TIMON, of Athens, the noted misanthrope, celebrated in Shakespeare's play, lived during the Peloponnesian War. He is more than once alluded to by Aristophanes and other comedians. Plutarch introduces a short account of his life in his biography of Mark Antony (ch. 70), who built a retreat called Timonium (Strabo xvii. 794) at Alexandria Timon also gave his name to one of Lucian's dialogues.

TIMON (320?–230), of Phlius, Greek sceptic philosopher and satirical poet, a pupil of Stilpo the Megarian and Pyrrho of Elis Having made a fortune by lecturing in Chalcedon he retired to Athens, where he died His writings (Diogenes Laërtius, ix. ch. 12) were numerous both in prose and in verse. he is said to have written epic poems, tragedies, comedies and satyric dramas, besides the Σίλλοι, three books of sarcastic hexameter verses, written against the Greek philosophers

The fragments (*c* 140 lines) are printed in F W A Mullach, *Frag phil. graec.* i (1860)

TIMOR, the largest of the Lesser Sunda Islands, in the Malay Archipelago, the north-eastern part of which, together with a small enclave in the south (Ocussi-Ambeno), belongs to Portugal, whilst the south-western half belongs to Holland and forms part of the Dutch East Indies. Dutch Timor with Sumbawa, Sumba, Flores and the Alor and Solor Isles, forms a residency of the D.E. Indies known as Timor and dependencies, with a population of 1,143,626. Timor stretches from S W to N E for 300 m. and has a mean width of 60 m. It lies west of the Arafura Sea It is outside the great volcanic belt extending from Java eastwards but it is within the volcanic region, and has a volcanic peak near the centre of the island There are no active volcanoes, but mud geysers exist It differs greatly from the other Lesser Sunda Islands, being traversed by a series of parallel mountain chains, with outliers in many places, especially on the eastern coast, descending to the sea. The centre of the country is a confused mass of very steep mountains. There are ridges from 4,000 to 8,000 ft in height, whilst the highest peak is Mt Rameau, 9,600 ft, in the centre of Portuguese Timor Mt Durulau, near it, is 8,300 and Mt. Suro 7,500 ft More than 20 other mountains range from 3,500 to 6,500 ft along or near the Dutch-Portuguese boundary

The geological structure of Timor is Archaean rock, with Permian beds, chiefly of limestone, containing numerous fossils Volcanic rocks are present Off the south-western coast are the islands of Semau, Rotti and Savu Semau (which has some remarkable springs) is small and unimportant Rotti, which is much larger, has well-developed Triassic beds and volcanic material It has extensive plains, several streams useful for agriculture, and many inlets, of which Buka Bay is the largest Savu is more than half the size of Rotti The climate differs considerably from that of Java and Sumatra, there being a short rainy season and a prolonged dry period Many trees lose their leaves during the dry season A temperature of 104° is reached

Fauna and Flora.—The flora has Australian forms, such as the eucalyptus. Vegetation is scanty and scrubby generally, though the uplands yield fairly under cultivation The woodlands, which nowhere form fine forests, contain much excellent sandalwood The fauna of Timor is of special interest since it proves, conclusively, that Timor has never formed part of Australia within recent geological epochs. The deep sea channel between has proved such an obstacle that only one Australian type is found—a marsupial, the cuscus (*Phalanger orientalis*), whereas Asiatic types include the grey monkey (*Macacus cynomologus*), deer, wild pig, civet-cat, shrew mouse, bat and a particular species of wild-cat, *Felis megalotis*, which is found only in Timor and Rotti As regards birds, there is a slight preponderance of Asiatic over Australian. Amongst the insects are few beetles, a rare rose-chafer (*Lomaptera timorensis*), such moths as the *Noctuae*, a new species of *Ophiodes*, *Remiga virbia*, and a humming-bird moth (*Protoparce orientalis*), and many butterflies, Pieridae and Lycaenidae being common, others including the rare and beautiful swallow-tails *Papilio aenomaus* and *P. liris*, and the deep purple-winged *Cethosia leschenaultii*. The very few land shells of Timor are allied to or identical with Moluccan and Celebes forms There are snakes, and a species of crocodile.

The soil of the plains is poor and as the Timorese have a very scanty knowledge of irrigation and primitive means of ploughing, cultivation is backward The mineral resources of Timor include gold, copper, gypsum and petroleum, but little or nothing has been done to use them.

The population of Timor is about 800,000, that of Rotti 46,823, and of Savu 27,365. It includes very few Europeans and Eurasians, or foreign Asiatics (the latter being mostly Chinese, with a small number of Arabs), and consists of Timorese, a much-mixed race, probably Malayo-Papuan-Polynesian. There is a more pronounced strain of Malayan blood in the people about the coast, whilst in the west (Kupang, Semau, etc.), there has been intermingling with the people of Rotti and Savu, who are lighter-complexioned, good-looking, well-featured people, of Malayan (and probably Polynesian) stock Inland amongst the mountains live the native Timorese, generally a dusky brown or blackish people, slender-figured and of tall or medium height Forbes mentions a race of dwarfish people living in the Fatu Matabia mountains. There are small communities of Christian converts, Catholic and Protestant in Dutch Timor, Catholic in Portuguese Timor, and a few Mohammedans along the coast The people of Rotti and Savu are largely Christian, and Mohammedan Except along the coast, the Timorese have been little touched by civilization They lead a very primitive life and are often at war with each other, there being numbers of small native kingdoms, under both Dutch and Portuguese rule The usual dress of the men consists of two pieces of patterned cottoned material, with a decorated belt, often a sort of shawl, thrown over the shoulder when not in full use, and sometimes a kind of turban headgear, and a cloth wallet is carried Women wear a *sarong*, also with a shawl, and they are fond of armlets of gold and silver, necklaces of glass, quartz or clay, and gold and silver chest plaques. Chiefs have special decorative garments tattooing is practised Weapons are the bow and arrow, spear (and shield), sword, and blow-pipe, for hunting, the use of the gun is known, and the men are very good horsemen The usual Timorese house is built of wood, on piles, and is round in shape, with a roof of grass or palm-leaf thatch, and only one room, (except in the case of chiefs and other notables), villages, and sometimes houses often being stockaded. There was a special hut in which the leader of a successful head-hunting expedition underwent purification—to appease the ghosts of the slain Pomali, or taboo, is very prevalent in Timor, and apart from the custom of placing a palm branch, as a sign of taboo, before fruit-trees, houses, growing crops, etc, to protect them—an effective method of preventing robbery—villages possess a regular *pomali* house, known as the *Uma-Luli*. It stands in a cleared space, within which not a stone may be overturned, or a twig plucked The building itself is raised above the ground on pillars and has two doors, one at the side and one at the end The presiding official at the ceremonies of *pomali* is known as the *Dato Luli*, and has great power Certain relics are preserved in the *pomali* house and there is a special part reserved where offerings are made to the *Vatu Luli*, or sacred stone Some houses have a *Luli* chamber, where sacrifices of animals (pigs) are made and where a bunch of rice is hung—to ensure a bountiful harvest. The dead are placed on a stage raised above the ground, sometimes covered with a roof, and kept until a burial feast can be arranged Stone carved seats for graves are known in Rotti

Polygamy and concubinage are practised, but not cleanliness Industry consists of weaving, plaiting and the manufacture of ornaments and weapons. Fishing and copra manufacture occupy people along the coast Trade is mostly in Chinese, Arab and Malay (Bugis) hands. Many languages and dialects are spoken. Rotti and Savu have languages of their own

History.—The first Dutch landing on Timor was in 1613 (the Portuguese had settled there nearly 100 years before), after a Portuguese garrison had been driven out of a fort on the neighbouring island of Solor. The Raja of Kupang permitted a settlement and from 1619 onwards the Dutch remained there Their chief enemies were the "black" Portuguese of Occussi, whose allies were the Timorese of Ambenu and Amarassi, and occasionally the white Portuguese, from Portuguese Timor. In 1749 the whole combination invested Kupang, but the Dutch succeeded in relieving the garrison and the Portuguese were almost annihilated Twenty years later the Portuguese, whose headquarters had been Lifau, in Occussi, made Dilli their capital,

but the "black" Portuguese of Occussi continued their attacks on the Dutch at Kupang, who, beyond making a treaty with 15 of the neighbouring Timorese chiefs, did little to resist them In 1797 the Dutch, who by this time had extended their influence as far as Atapupu, were in sufficient force to resist successfully a British attempt to take possession of Timor in the name of the Prince of Orange, which they repeated on the occasion of a second British attempt, in 1810, but after the capitulation of Java, the Dutch flag on Timor was hauled down, and during the period of British rule the Portuguese seized the Dutch district of Atapupu, being ejected therefrom by the Dutch when Timor was handed back to them by the Convention of 1814, though this led to many "incidents" and frontier disputes

The Dutch claimed the western half of Timor, but no attempt had been made to delimit frontiers A Dutch offer to buy out the Portuguese was refused, and in 1851 the attempt of a Portuguese Commissioner to fix a boundary was repudiated by his Government In 1859, however, a treaty was signed in which the main boundary through the centre of the island was described, and also the boundaries of the enclaves, claimed by both parties, though no previous survey had been made In 1893 a Convention was signed agreeing to carry out a survey of the main boundary, and, if possible, abolish enclaves In 1898 a Boundary Commission was set up, the main boundary was surveyed first, and then the boundaries of the enclaves, the task being complicated by dissensions amongst the native chiefs concerned, who forcibly prevented the survey of territories in dispute between themselves In 1904 a treaty was made recording the new boundaries, but the ratification was postponed until the Occussi enclave survey could be carried out A mixed commission formed in 1909 stopped work owing to a dispute about the meaning of an article of the Treaty of 1904, there were frontier affrays in 1913, and then came further treaty disagreement, resulting in recourse to arbitration In 1914 the Swiss Plenipotentiary at Paris, M Lardy, a member of the Hague Court of Arbitration, decided in favour of the Dutch view of the track of the eastern frontier of the Occussi enclave, Portugal accepted it and the Treaty of 1904 was then carried into effect

Dutch Timor has an area of a little more than 5,000 sq m, with a population of about 360,000 The capital, Kupang, and the seat of the Resident, is situated on Kupang Bay, in the extreme west of the island It has a harbour, and is the chief port, the only other port being Atapupu, on the western coast, near the boundary between Dutch and Portuguese Timor Both ports (also Baa, in Rotti, and Seba, in Savu), are places of call for vessels of the Royal Packet Navigation Company, which give communication with the other Lesser Sunda Islands, with Celebes, and with Java Kupang, which has a population of 5,493 (275 Europeans and Eurasians, and 1,286 foreign Asiatics, mostly Chinese), is a difficult port during the north-west monsoon Other towns are Sukubianaua, Sufa, Tiamplong, Putain, Lalogama and Atambua. Exports from Timor and Dependencies during 1926 were 66,974 and imports 234,714 guilders, consisting chiefly of sandal-wood, copra, ponies, cattle and hides Lack of inland communication hinders the development of the country Beyond a riding road across country from Kupang to Atapupu, and thence southwards, roads do not exist, but money has been voted for a survey on which to base a plan for road construction. Timor has no cable connection with Java or any other part of the Archipelago, but Kupang has a wireless station.

Portuguese Timor has an area of 18,989 sq kilometres The population is 442,261, the most heavily populated district being that of Motael, in which the capital, Dilli, is situated Until 1896 Portuguese Timor was joined administratively to the Portuguese colony of Macao, in China, but in 1896 it became autonomous, under a governor, who resides at Dilli, which is also the chief port of the colony, and is served by vessels of the Dutch Royal Packet Navigation Company, there being no Portuguese steamship service between Portuguese Timor and other parts of the Malay Archipelago, but a small Portuguese steamer takes cargo to Kupang. Its population is 3,500. Other towns are Liquica, Manatuto and Baucan, on the west coast Exports from Portuguese Timor in 1926 were 1,235,878 patacas and imports 1,168,242 patacas, chief exports being coffee, copra, hides, cocoa, shells and wax; imports cotton piece-goods, petroleum and wine.

TIMOR LAUT, TENIMBAR or **TENIMBER** (Dutch, TIMOR LAOET), a group of islands in the Malay Archipelago, south-west of the Aru Islands, between 6° 20′ and 8° 30′ S, and 130° 40′ and 132° 5′ E They are on the Archaean Ridge on which the Kei Isles stand, most are of recent coralline formation, and some are volcanic There are 66 islands, the largest being Yamdena, with an area of 1,100 sq m, 74 m long by 26 Thickly wooded hills extend along the east coast, the west coast is lower, where, opposite the island of Seira, a gulf extends far inland In places there are precipitous cliffs, and a narrow foreshore fringed with coco-nut palms and mangrove There are many small islands off the western coast of Yamdena—Seira, Wuliaru, Wotar and Laibobar The largest, Laibobar, has a volcano over 1,500 ft. Off the north-eastern coast of Yamdena, is Larat (15 m by 6), with a rocky coast and high cliffs, and with thick vegetation along the foreshore, beyond Larat lies Vordata, which is high, and off the south-western coast, separated by Egerton Strait, Selaru, which is about 30 m long, rather flat, and less wooded than Yamdena and Larat and with much grass land Other islands are Molu and Selu There are extensive swamps on many of the islands and the climate is not good, fever being very prevalent during the south-east monsoon The soil supports crops such as maize, rice (in small stretches), coco-nut and sago palms, yams and fruit such as plantains, mangoes and papayas Maize is the staple food There are practically no rivers and there is a lack of fresh water. The slight depth of soil prevents trees from attaining great height The flora includes sterculias and fig trees (*F rostigma*), leguminosae (trees and shrubs), myrtles, the scarlet hibiscus, pandans, palms, and a species of bread-fruit tree There are rare and lovely orchids of many kinds, crotons, dracaenas, and many varieties of ferns The fauna, a poor one, except in birds, comprises wild buffaloes, in large herds, wild pig, the *cuscus*, flying fox, many snakes, lizards and frogs, and 60 species of birds, including the scarlet lory (*Eos reticulata*), honey-eater (*Philemon timorlaoensis*), ground thrush (*Geocichla machiki*), and oriole (*Oriolus decipiens*) Butterflies are numerous, and include *Papilio aberram*, and amongst the beetles is a gorgeous golden-coloured buprestid (*Cyphogastra splendens*)

The estimated population of Timor Laut is about 25,000 The people are undoubtedly a mixed race Some of the men are tall, and handsome-featured, with well-formed bodies, others are short and thick-set, the complexion of nearly all being a rich chocolate brown. Forbes thinks, and the writer, who has studied them, agrees, that they are Malayo-Papuan-Polynesian, the islands being, probably, the last occupied by the Polynesian race during its eastern migration to the remote archipelagoes of the Pacific, some being left behind—to mingle with Papuans and Malays, the former, probably being the aboriginals and the latter settlers There are still many pagans, and a few Mohammedans Christianity is making rapid headway and has succeeded, with direct Dutch rule, in extirpating cannibalism, piracy, slavery, head-hunting and inter-tribal fighting. Male Christians wear cotton coats and short breeches, or *sarong;* the women wear *sarong* and *kebayah,* or bodice.

The pagan costume consists of loin-cloth, with a girdle, and, as full dress, bangles, armlets, ear-rings, necklaces, and a head-dress of bright-coloured cloth with bunches of flowers and bird plumes. The women wear a short *sarong*, suspended from a belt, have necklaces and ear-rings of bone, ebony and ivory, also of gold and silver, many bangles and artistically carved combs. They carry burdens in a basket on the back, suspended from

bands placed around the forehead. The men sometimes dye their hair a golden colour. Tattooing is known. They are a pleasant, trustful and fairly honest people, but the men are indolent, and the women do most of the work. Their artistic ability is high, and their houses of wood and *atap*, sometimes built in closely-packed settlements, generally on piles and entered from underneath, have carved pillars and show much artistry of construction. The men are skilful boat-builders, use the spear and bow and arrow (with which they are adept in shooting fish), hunt, search for trepang and tortoise-shell, are agriculturists, keep pigs and work in iron, copper and gold. The women cultivate the fields after the men have prepared the soil, weave and dye *sarongs*, and plait. Villages own an *Orang kaya*, or head man, but the people are communal and independent A favourite idol is termed *Duadilah*, the Sun-god.

Timor Laut, with two divisions, Larat and Saumlakki, is attached to the residency of Amboyna. The capital of Yamdena is Saumlakki at the south-western end of the island, and of Larat, the town of the same name, on the narrow strait which end, opposite Yamdena

The Timor Laut isles were first visited by Capt. Owen Stanley, in 1839, and became known to Banda traders in 1877. In 1878 H. O. Forbes, with his wife, visited the islands and stayed there three months, being warned before going, by the Dutch authorities, of the hostility and savagery of the inhabitants; for all practical purposes, he appears to have been the first European to have stayed any length of time in Timor Laut. Since his visit, the islands have been opened up by the Dutch, and the people have proved very responsive to outside civilizing influences, whilst trade is improving. (E. E. L.)

TIMOTEAN, a considerable group of tribes of South American Indians, forming an independent linguistic stock The Timotes and related tribes occupied the region about Merida and Truxillo and the valley of the Motatan river in western Venezuela Most of them are now extinct They were in general a warlike people, using javelins, spears and clubs, some also having poisoned arrows. A sedentary, agricultural folk, living in large communal houses, the men wore only a small cloth, the women either a very small apron or a cotton gown, belted at the waist

See P. de Aguado, *Historia de Venezuela* (Madrid, 1918).

TIMOTHEUS, Athenian statesman and general. son of Conon, the restorer of the walls of Athens. From 378–356 B C. he frequently held command in the war between Athens (in alliance with Thebes), and Sparta In 375 Timotheus was sent with a fleet to sail round Peloponnesus by way of demonstration against Sparta He gained over Cephallenia, secured the friendship of the Acarnanians and Molossians, and took Corcyra, but used his victory with moderation. In 373 Timotheus was appointed to the command of a fleet for the relief of Corcyra, then beleaguered by the Spartans. But his ships were not fully manned, and to recruit their strength he cruised in the Aegean. For this delay he was brought to trial, but acquitted. Having been superseded in his command he took service with the king of Persia. We next hear of him about 366, when, having returned to Athens, he was sent to support Ariobarzanes, satrap of Phrygia. But, finding that the satrap was in open revolt against Persia, Timotheus, in conformity with his instructions, abstained from helping him and turned his arms against Samos, then occupied by a Persian garrison, and took it after a ten months' siege (366–65) He then took Sestus, Crithote, Torone, Potidaea, Methone, Pydna and many other cities; but two attempts upon Amphipolis failed. An action was brought against him by Apollodorus, the son of the banker Pasion, for the return of money lent by the father. The speech for the plaintiff is still extant, and is attributed (though not unanimously) to Demosthenes. In the course of the Social War Timotheus was despatched with Iphicrates, Menestheus, son of Iphicrates, and Chares to put down the revolt. The hostile fleets sighted each other in the Hellespont; but a gale was blowing, and Iphicrates and Timotheus decided not to engage. Chares, disregarding their opposition, lost many ships, and in his despatches he complained so bitterly of his colleagues that the Athenians put them on their trial. Timotheus, who had always been disliked for his arrogance, was condemned to pay a very heavy fine. Being unable to pay, he withdrew to Chalcis, where he died soon afterwards. The Athenians showed their repentance by remitting the greater part of the fine to his son Conon. His remains were buried in the Ceramicus and statues erected to his memory in the agora and the acropolis.

See Life by Cornelius Nepos; Diodorus Siculus xv., xvi.; Isocrates, *De permutatione;* Pseudo-Demosthenes, *Adversus Timotheum;* C. Rehdantz, *Vitae Iphicratis, Chabriae, Timothei* (1845); and especially Holm, *Hist. of Greece* (Eng. trans, vol. iii.).

TIMOTHY or **TIMOTHEUS** in the New Testament was one of the younger companions of the Apostle Paul. He was connected with Lystra in Lycaonia, born of a pagan father and of a Jewish mother called Eunice, his grandmother being also a Christian When the apostle came across him at home, he was still uncircumcised, but a full member of the church at Lystra (Acts xvi. 1f., 2 Tim. i 5f.). As the defection of Barnabas and Mark had left St. Paul alone, he took Timotheus with him as a colleague, first of all circumcising him out of respect to the prejudices of the communities in which he was to do mission work This was a matter of convenience, not of principle. He accompanied St. Paul and Silas to Europe, where he was employed by them on various missions, especially among the Macedonian churches which he helped to found. But Corinth as well as Thessalonica and Philippi drew out his activities as an "apostle" in the wider sense of the term (2 Cor. i 19, etc). From Corinth he appears to have accompanied the apostle to Ephesus and Asia Minor (Acts xix. 22, 1 Cor. xvi 10 *seq.*). He is then associated with St Paul in his imprisonment, as the collocation of his name in the titles of Colossians, Philemon and Philippians indicates, whether that imprisonment was at Rome or elsewhere. In the Pastoral Epistles (*q v*) he is absent from his chief, in charge of work at Ephesus, and there is a notice of him in Hebrews (xiii 23), which chronicles his release from imprisonment, though there is no clue to its date or place. Tradition, probably based on inferences from the New Testament, made him bishop of Ephesus, where it is said he was martyred under Domitian, one legend asserting that he was clubbed to death by the mob for protesting against the orgies of Artemis worship. The Greek martyrology celebrates his death on Jan 22, the Latin on Jan. 24. (J. Mof.)

TIMPANI (It.), in music, the Italian name for kettledrums. (*See* Drum.)

TIMŪR (*Timur i Leng*, the lame Timūr), commonly known as Tamerlane, the renowned Oriental conqueror, was born in 1336 at Kesh, better known as Shahr-i-Sabz, "the green city," 50 m. south of Samarkand in Transoxiana. His father Teragai was head of the tribe of Berlas Great-grandson of Karachar Nevian (minister of Jagatai, son of Jenghiz Khan, and commander-in-chief of his forces), and distinguished among his fellow-clansmen as the first convert to Islamism, Teragai might have assumed the high military rank which fell to him by right of inheritance; but like his father Burkul he preferred a life of retirement and study. At the age of twenty Timūr had not only become an adept in manly outdoor exercises but had earned the reputation of being an attentive reader of the Koran.

About 1358, however, he came before the world as a leader of armies. His career for the next ten or eleven years may be thus briefly summarized from the *Memoirs*. Allying himself both in cause and by family connection with Kurgan, the dethroner and destroyer of Kazan, chief of the western Jagatai, he was deputed to invade Khurasan at the head of a thousand horse. This was the second warlike expedition in which he was the chief actor, and the accomplishment of its objects led to further operations, among them the subjection of Khwarizm and Urganj. After the murder of Kurgan the contentions which arose among the many claimants to sovereign power were arrested by the invasion of Toghluk Timūr of Kashgar, a descendant of Jenghiz. Timūr was despatched on a mission to the invader's camp, which led to his appointment to the government of Māwarā-'lnahr (Transoxiana).

By the death of his father Timūr was also left hereditary head of the Berlas. The exigencies of his quasi-sovereign position compelled him to have recourse to his formidable patron, whose reappearance on the banks of the Sihon created a consternation not easily allayed. Māwarā'lnahr was taken from Timūr and entrusted to a son of Toghluk; but he was defeated in battle by the bold warrior he had replaced at the head of a numerically far inferior force. Toghluk's death facilitated the work of reconquest, and a few years of perseverance and energy sufficed for its accomplishment, as well as for the addition of a vast extent of territory. During this period Timūr and his brother-in-law, Hosain—at first fellow-fugitives and wanderers in joint adventures full of interest and romance—became rivals and antagonists. At the close of 1369 Hosain was assassinated and Timūr proclaimed sovereign at Balkh, mounted the throne at Samarkand.

The next thirty years or so were spent in various wars and expeditions. Timūr not only consolidated his rule at home by the subjection of intestine foes, but sought extension of territory by encroachments upon the lands of foreign potentates. His conquests to the west and north-west led him among the Mongols of the Caspian and to the banks of the Ural and the Volga; those to the south and south-west comprehended almost every province in Persia, including Baghdad, Kerbela and Kurdistan. One of the most formidable of his opponents was Toktamish, who after having been a refugee at the court of Timūr became ruler both of the eastern Kipchak and the Golden Horde, and quarrelled with Timūr over the possession of Khwarizm It was not until 1395 that the power of Toktamish was finally broken. (*See* MONGOLS; GOLDEN HORDE.)

In 1398, when Timūr was more than sixty years of age, Farishta tells us that, "informed of the commotions and civil wars of India," he "began his expedition into that country," and on Sept. 12, "arrived on the banks of the Indus." His passage of the river and upward march along the left bank, the reinforcement he provided for his grandson Pir Mahommed (who was invested in Multan), the capture of towns or villages accompanied, it might be, with destruction of the houses and the massacre of the inhabitants, the battle before Delhi and the easy victory, the triumphal entry into the doomed city, with its outcome of horrors—all these circumstances belong to the annals of India In April 1399, some three months after quitting the capital of Mahmūd Toghluk, Timūr was back in his own capital beyond the Oxus. It need scarcely be added that an immense quantity of spoil was conveyed away According to Clavijo, ninety captured elephants were employed to carry stones from certain quarries for Timūr to erect a mosque at Samarkand.

The war with the Turks and Egyptians which succeeded the return from India was rendered notable by the capture of Baghdad, Aleppo and Damascus, by the great victory over the Turks at Angora (1402), where the Sultan Bayezid I. was captured, and thereafter dragged in the conqueror's train. (*See* TURKEY: *History,* and EGYPT: *History,* Mohammedan period.) This was Timūr's last campaign. Another was projected against China, but he was attacked by fever when encamped on the farther side of the Sihon (Syr-Daria) and died at Atrār (Otrar) on Feb. 17, 1405. Markham, in his introduction to the narrative of Clavijo's embassy, states that his body "was embalmed with musk and rose water, wrapped in linen, laid in an ebony coffin and sent to Samarkand, where it was buried." Timūr had carried his victorious arms on one side from the Irtish and the Volga to the Persian Gulf and on the other from the Hellespont to the Ganges.

Timūr's generally recognized biographies are—'Alī Yazdī, commonly called Sharifu 'd-Dīn, author of the Persian *Zafarnāma,* translated by Petis de la Croix in 1722, and from French into English by J. Darby in the following year; and Ahmad ibn Mohammed ibn Abdallah, al Dimashki, al 'Ajmi, commonly called Ibn 'Arabshāh, author of the Arabic *'Ajaibu 'l Makhlnkāt,* translated by the Dutch Orientalist Golius in 1636.

There are also the *Memoirs* (*Malfūzāt*) and *Institutes* (*Tuzukāt*), of which an important section is styled *Designs and Enterprises* (*Tadbīrāt wa Kangāshahā*). Upon the genuineness of these doubt has been thrown. The circumstance of their alleged discovery and presentation to Shah Jahān in 1637 was of itself open to suspicion

There are supposed likenesses of Timūr in the collections of Oriental mss. and drawings in the British Museum In Marlowe's *Tamburlaine* Timūr is described as tall of stature, straightly fashioned, large of limb, having joints strongly knit, long and sinewy arms, a breadth of shoulders to "bear old Atlas's burden," pale of complexion, and with "amber hair wrapp'd in curls" The outline of this description might be from Sharifu 'd-Dīn, while the colours are the poet's own.

Apart from modern European *savants* and historians, and the more strictly Oriental chroniclers who have written in Persian, Turkish or Arabic, the following authorities may be cited—Laonicus Chalcondylas, Joannes Leunclavius, Joachimus Camerarius, Petrus Perondinus Lazaro Soranzo, Simon Mairlus, Matthew Michiovius. A score or so of other names are given by Samuel Purchas. *See* also Sir Clements Markham's *Clavijo,* in the Hakluyt Society's publications; White's edition of Davy's translation of the *Institutes* (1783), Stewart's translation of the *Malfūzāt;* Malcolm's *History of Persia;* and *Trans Roy Soc.* (1885); Horn, "Gesch Irans in islam. Zeit," in Geiger and Kuhn, *Grundr. der iranisch. Philol.* (1904); works quoted, *s v* MONGOLS. (F. J. G.)

TIN, a metallic chemical element, symbol Sn (Lat. *stannum*) atomic number 50, atomic weight 118 70. Being a component of bronze, it was used as a metal thousands of years prior to the dawn of history; but it does not follow that prehistoric bronzes were made from *metallic tin.* When the unalloyed metal was first introduced cannot be ascertained with certainty. The "tin" of the Bible corresponds to the Hebrew *bedhil,* which is really a copper alloy known as early as 1600 B.C. in Egypt. All we know is that about the 1st century the Greek word *κασσίτερος* designated tin, and that tin was imported from Cornwall into Italy after, if not before, the invasion of Britain by Julius Caesar From Pliny's writings it appears that the Romans in his time did not realize the distinction between tin and lead: the former was called *plumbum album* or *candidum* to distinguish it from *plumbum nigrum* (lead proper) The word *stannum* definitely assumed its present meaning in the 4th century

Grains of metallic tin occur intermingled with the gold ores of Siberia, Guiana and Bolivia, and in a few other localities Of minerals containing this element mention may be made of cassiterite (*q.v.*) or tinstone, SnO_2, and tin pyrites, $Cu_4SnS_4+Fe_2SnS_4$; the metal also occurs in some epidotes, and in company with columbium, tantalum and other metals Of these "tinstone" is of the greatest commercial importance. It occurs in its matrix, either in or closely associated with fissure veins or disseminated through rock masses. It is also found in the form of rolled lumps and grains, "stream tin," in alluvial gravels; the latter are secondary deposits, the products of the disintegration of the first-named primary deposits. Almost everywhere primary deposits of tinstone are in or closely connected with granite or acid eruptive rocks of the same type, its mineral associates being tourmaline, fluorspar, topaz, wolfram and arsenical pyrites, the commonest gangue being quartz An exception to this mode of occurrence, however, is to be found in Bolivia where the tin ore occurs intimately associated with silver ores bismuth ores and various sulphides, whilst the gangue includes barytes and certain carbonates. Over five-sixths of the world's total production is derived from secondary alluvial deposits, but the tin obtained in Cornwall (where the alluvial deposits have been worked out) and Bolivia is from vein mining, while a small portion of that yielded by Australasia comes from veins and from granitic rocks carrying disseminated tinstone.

Production.—During the 18th century the world's supply of tin was mainly from England, Saxony and Bohemia; in 1801 England produced about 2,500 tons, while the supplies of Saxony and Bohemia had been greatly diminished. The English supply then gradually increased to about 10,000 tons in 1860, and this figure was fairly well sustained until about 1890, when a period of depression to about 4,000 tons set in In the opening decades of the 19th century supplies began to be drawn from the island of Banka. Billiton became of note in 1853. The Straits Settlements ranked as an important producer in 1870 and now produce a large part of the world's supply. Australian deposits were worked in 1872, and those of Bolivia somewhat later. The production of Nigeria, though relatively small, shows the greatest proportional increase in the twelve years 1915–1926. The following table shows the output (in tons) of the largest producers and also the total world's output for certain recent years

	1915	1920	1925	1926
Federated Malay States	46,756	34,935	45,925	45,946
Bolivia	21,544	27,821	32,980	32,113
Dutch East Indies	19,255	21,181	32,704	33,006
Nigeria	4,837	5,168	6,175	7,042
China	7,095	10,566	8,789	6,538
Siam	8,998	6,201	6,802	6,978
Total (all countries) .	126,872	122,097	145,437	143,968

Properties.—An ingot of tin is pure white (except for a slight tinge of blue); the colour depends, however, upon the temperature at which it is poured—if too low, the surface is dull, if too high, iridescent. It exhibits considerable lustre and is not subject to tarnishing on exposure to normal air. The metal is fairly soft and easily flattened out under the hammer, but almost devoid of tenacity. That it is elastic, with narrow limits, is proved by its clear ring when struck with a hard body in circumstances permitting of free vibration The specific gravity of cast tin is 7 29, of rolled tin 7·299 and of electrically deposited tin 7 143 to 7·178 A tin ingot is distinctly crystalline; hence the characteristic crackling noise, or "cry" of tin, which a bar of tin gives out when being bent. This structure can be rendered visible by superficial etching with dilute acid; and as the minuter crystals dissolve more quickly than the larger ones, the surface assumes a frosted appearance (*moirée métallique*) The metal is bimorphous by cooling molten tin at ordinary air temperature tetragonal crystals are obtained, while by cooling at a temperature just below the melting point rhombic forms are produced. When exposed for a sufficient time to very low temperatures (to —39° C for 14 hours), tin becomes so brittle that it falls into a grey powder, termed the *grey modification,* under a pestle; indeed, when kept in cold climates for several years, it sometimes crumbles into powder spontaneously (*see* ALLOTROPY). At ordinary temperatures tin proves fairly ductile under the hammer, and its ductility seems to increase as the temperature rises up to about 100° C. At some temperature near its fusing point it becomes brittle, and still more brittle from —14° C downwards. Iron renders the metal hard and brittle; arsenic, antimony and bismuth (up to 0 5%) reduce its tenacity; copper and lead (1 to 2%) make it harder and stronger but impair its malleability; and stannous oxide reduces its tenacity. Tin fuses at about 230° C; at about 1,600° C it begins to volatilize slowly; at about 2,270° C it boils The hot vapour produced combines with the oxygen of the air into white oxide, SnO_2. Its coefficient of linear expansion between 0° and 100° is 0·002717; its specific heat 0 0562; its thermal and electrical conductivities are 145 to 152 and 114 5 to 140·1 respectively, compared to silver as 1,000. The metal is scarcely affected by dilute hydrochloric or sulphuric acids; very dilute nitric acid slowly dissolves it, but strong acid converts it to β-stannic acid (*see* below); concentrated hydrochloric acid attacks it fairly readily, and concentrated sulphuric acid when hot.

Industrial Applications.—Commercially pure tin is used for making such apparatus as evaporating basins, infusion pots, stills, etc. It is also employed for making two varieties of tin-foil—one for the silvering of mirrors (now superseded) the other for wrapping up chocolate, toilet soap, tobacco, etc The mirror foil must contain some copper to prevent it from being too readily amalgamated by the mercury. For making tin-foil the metal is rolled into thin sheets, pieces of which are beaten out with a wooden mallet. As pure tin does not tarnish in the air and is proof against acid liquids, such as vinegar, lime juice, etc., it is utilized for culinary and domestic vessels. But it is expensive, and tin vessels have to be made very heavy to give them sufficient stability of form; hence it is generally employed merely as a protecting coating for utensils made of iron usually. (*See* TIN-PLATE.) Rolled plates of mild steel are "pickled" in dilute hydrochloric or sulphuric acid, annealed, cold rolled, re-annealed at a lower temperature, again pickled in weaker acid, and washed with water They are then tinned by passing through a bath of the molten metal which is divided into two sections and so arranged that the plate passes through a flux of molten zinc chloride floating on the metal in the first section, and emerges through a coating of grease floating on the metal in the second section; they are then rolled in order to remove excess of tin and to impart polish to the surface

By far the greater part of the tin produced metallurgically is used for making alloys. Ordinary solder is a mixture of equal parts of tin and lead; pewter (*q.v*) is 3 parts of tin to 1 part of lead. Locomotive bearings are a lead-copper alloy containing about 8% of tin. Bronze (*q v*) is an alloy of tin with copper, and the properties differ greatly from those of either metal separately. Coinage bronze contains 5% of tin (with the addition of about 1% of zinc); bronzes containing 9–10% of tin are used as gun-metal, those having 10–12% are used as engineers' brasses, those with 12–15% for bearings and those with 16–24% for bells, the precise proportion depending upon the type of bell required Speculum metal contains 33% of tin and 67% of copper. All the properties of these alloys are, however, considerably modified by the rate of cooling, and processes such as hammering and cold working.

COMPOUNDS OF TIN

Tin forms two well-marked series of salts, in one of which it is bivalent, these salts being derived from stannous oxide, SnO, in the other it is quadrivalent, this series being derived from stannic oxide, SnO_2.

Stannous Oxide, SnO, is obtained in the hydrated form $2SnO\,H_2O$ from a solution of stannous chloride by addition of sodium carbonate; it forms a white precipitate, which can be washed with air-free water and dried at 80° C without much change by oxidation; if it be heated in carbon dioxide the black SnO remains Precipitated stannous hydrate dissolves readily in caustic potash; if the solution is evaporated quickly it suffers decomposition, with formation of metal and stannate,

$$2SnO + 2KOH = K_2SnO_3 + Sn + H_2O.$$

If it is evaporated slowly, anhydrous stannous oxide crystallizes out in forms which are combinations of the cube and dodecahedron. Dry stannous oxide, if touched with a glowing body, catches fire and burns to stannic oxide, SnO_2 Stannous oxalate when heated by itself in a tube leaves stannous oxide

Stannic Oxide, SnO_2—This, if the term is taken to include the hydrates, exists in a variety of forms (1) *Tinstone* (*see* above and also CASSITERITE) is proof against all acids. Its disintegration for analytical purposes can be effected by fusion with caustic alkali in silver basins, with the formation of soluble stannate, or by fusion with sulphur and sodium carbonate, with the formation of a soluble thiostannate (2) A similar oxide (*flores Jovis*) is produced by burning tin in air at high temperatures or exposing any of the hydrates to a strong red heat. Such *tin-ash,* as it is called, is used for the polishing of optical glasses; "putty powder" is another name for a similar preparation used for polishing. *Flores stanni* is a finely divided mixture of the metal and oxide obtained by fusing the metal in the presence of air for some time (3) *Metastannic acid* (generally written $H_{10}Sn_5O_{15}$, to account for the complicated composition of metastannates, *e g*, the sodium salt $H_8Na_2Sn_5O_{15}$) is the white compound produced from the metal by means of nitric acid. It is not the true meta-acid, however, and is therefore better called β-stannic acid (*see* below). It is insoluble in water and in nitric acid and apparently so in hydrochloric acid; but if heated with this latter for some time it passes into a more soluble compound, which is a basic chloride, β-stannyl chloride. β-stannic acid is distinguished from ortho- or α-stannic acid by its insolubility in nitric and sulphuric acids. The salts are obtained by the action of alkalis on the acid. (4) Orthostannic acid, so-called, is really the meta-acid and is better called α-stannic acid; it is obtained as a white precipitate on the addition of sodium carbonate or the exact quantity of precipitated calcium carbonate to a solution of the chloride. This acid, H_2SnO_3, is readily soluble in acids forming stannic salts, and in caustic potash and soda, with the formation of metastannates. Of these sodium stannate, Na_2SnO_3, is produced industrially by heating tin with Chile saltpetre and caustic soda, or by fusing very finely powdered tinstone with caustic soda in iron vessels. A solution of the pure salt yields

fine prisms of the composition $Na_2SnO_3+10H_2O$, which effloresce in the air. The salt is used as a mordant in dyeing and calico-printing, being called "preparing salts" in the latter industry Alkaline and other stannates when treated with aqueous hydrofluoric acid are converted into fluostannates or stannifluorides (*e.g.*, K_2SnO_3 into K_2SnF_6), which are closely analogous to, and isomorphous with, fluosilicates or silicifluorides.

A colloidal or *soluble stannic acid* is obtained by dialysing a mixture of tin tetrachloride and alkali, or of sodium stannate and hydrochloric acid. On heating it is converted into colloidal β-stannic acid A hydrated *tin trioxide*, $2SnO_3 \cdot H_2O$, has been described by Spring

Stannous chloride, $SnCl_2$, can only be obtained pure by heating pure tin in a current of pure dry hydrogen chloride. It is a white solid, fusing at 250° C to an oily liquid which boils at 606°, and volatilizing at a red heat in nitrogen, a vacuum or hydrogen chloride, without decomposition The vapour density below 700° C is somewhat high. but above 800° C corresponds to nearly $SnCl_2$ The chloride readily combines with water to form a crystallizable hydrate $SnCl_2 \cdot 2H_2O$, known as "tin salt" or "tin crystals" This salt is also formed by dissolving tin in strong hydrochloric acid and allowing it to crystallize, and is industrially prepared by passing sufficiently hydrated hydrogen chloride over granulated tin contained in stoneware bottles and evaporating the concentrated solution produced in tin basins over granulated tin The basin itself is not attacked The crystals are very soluble in cold water, and if the salt is really pure a small proportion of water forms a clear solution, but on adding much water most of the salt is decomposed, with the formation of a precipitate of oxychloride, $2Sn(OH)Cl \cdot H_2O$. The same oxychloride is produced when the moist crystals are exposed to the air Hence all tin crystals as kept in the laboratory give with water a turbid solution, which contains stannic in addition to stannous chloride The complete conversion of stannous into stannic chloride may be effected by a great many reagents—for instance, by chlorine (bromine, iodine) readily, by mercuric chloride, with precipitation of calomel or metallic mercury; by ferric chloride on warming, with formation of ferrous chloride; by arsenious chloride in strong hydrochloric acid solutions, with precipitation of brown metallic arsenic. All these reactions are available as tests for "stannosum" or, alternatively for the respective agents A strip of metallic zinc when placed in a solution of stannous chloride precipitates the tin in crystals and takes its place in the solution Stannous chloride is largely used in the laboratory as a reducing agent, in dyeing as a mordant

Stannic chloride, $SnCl_4$, named by Andreas Libavius in 1605 *Spiritus argenti vivi sublimati* from its preparation by distilling tin or its amalgam with corrosive sublimate, and afterwards termed *Spiritus fumans Libavii*, is obtained by passing dry chlorine over granulated tin contained in a retort; the tetrachloride distils over as a heavy liquid, from which the excess of chlorine is easily removed by shaking with a small quantity of tin filings and redistilling. It is a colourless fuming liquid of specific gravity 2·279 at 0° C; it freezes at $-33°$, and boils at 113·9°. The chloride unites energetically with water to form crystalline hydrates (*e g*, $SnCl_4 \cdot 3H_2O$), easily soluble in water With one-third its weight of water it forms the so-called "butter of tin" It combines readily with alkaline and other chlorides to form double salts, *e g*, M_2SnCl_6, analogous to the chloroplatinates; the salt $(NH_4)_2SnCl_6$ is known industrially as "pink salt" on account of its use as a mordant to produce a pink colour. The *oxymuriate of tin* used by dyers is $SnCl_4 \cdot 5H_2O$. The plain chloride solution is similarly used. It is usually prepared by dissolving the metal in aqua regia (*q.v.*).

Stannous fluoride, SnF_2, is obtained as small, white monoclinic tables by evaporating a solution of stannous oxide in hydrofluoric acid in a vacuum. *Stannic fluoride*, SnF_4, is obtained as white hygroscopic crystals from stannic chloride and anhydrous hydrofluoric acid at a high temperature; it forms a characteristic series of salts, the stannifluorides, M_2SnF_6, isomorphous with the silici-, titani-, germani- and zirconi-fluorides *Stannous bromide*, $SnBr_2$, is a light yellow substance formed from tin and hydrobromic acid. *Stannic bromide*, $SnBr_4$, is a white crystalline mass, melting at 33° and boiling at 201°, obtained by the combination of tin and bromine, preferably in carbon bisulphide solution *Stannous iodide*, SnI_2, forms yellow red needles, and is obtained from potassium iodide and stannous chloride *Stannic iodide*, SnI_4, forms red octahedra and is prepared similarly to stannic bromide. Both iodides combine with ammonia

Stannous sulphide, SnS, is obtained as a lead-grey mass by heating tin with sulphur, and as a brown precipitate by adding sulphuretted hydrogen to a stannous solution; this is soluble in ammonium polysulphide, and dries to a black powder. *Stannic sulphide*, SnS_2, is obtained by heating a mixture of tin, mercury, sulphur and sal-ammoniac (in the proportions 12, 6, 7 and 6 respectively) in the beautiful form of *aurum musivum* (mosaic gold)—a solid consisting of golden yellow, metallic lustrous scales, and used chiefly as a yellow "bronze" for plaster-of-Paris statuettes, etc The yellow precipitate of stannic sulphide obtained by adding sulphuretted hydrogen to a stannic solution readily dissolves in solutions of the alkaline sulphides to form *thiostannates* of the formula M_2SnS_3; the free acid, H_2SnS_3, may be obtained as an almost black powder by drying the yellow precipitate formed when hydrochloric acid is added to a solution of a thiostannate

Organic Compounds of Tin.—Numerous organic compounds of tin are known, such as tin tetraethyl, $Sn(C_2H_5)_4$ Where the four radicals are different, the compound can exist in enantiomorphous forms (*see* STEREOCHEMISTRY); thus W J. Pope and his collaborators (1900–1902) resolved methylethylpropyl tin iodide, $Sn(CH_3)(C_2H_5)(C_3H_7)I$, into dextro- and laevo-modifications. Compounds of tin with β-diketones (*see* KETONES) are also known The simplest is stannic bisacetylacetone dichloride, $Sn(C_5H_7O_2)_2Cl_2$ (W. Dilthey, 1902), and G T Morgan and H D K Drew (1920) showed that in all such compounds with univalent β-diketones tin has a co-ordination number of 6, *i e*, the constitution is $[R_2SnX_2]$, X being a halogen atom, and the same co-ordination number is found in "pink salt" (*see* above), $[SnCl_6](NH_4)_2$ A co-ordination number of 8 is, however, indicated in tetra-aquabisacetylacetone stannibromide $[Sn(C_5H_7O_2)_2, 4H_2O]SnBr_6$

Methyl stannic iodide (stanniform), CH_3SnI_3, a yellow crystalline substance melting at 87° C, has been applied in therapeutics (1929) as antiphlogistic, analgesic and antiseptic, it combines the usefulness of tin in staphylococcic infections with the powerful germicidal properties of iodine

Hydrides.—A hydride, SnH_4, of melting point $-150°$ C, has been obtained by electrolysis of a stannous sulphate solution between lead electrodes, a trace of colloids (*e g*, 0·5% of dextrin) being used as a stabilizer; it forms only about 0·01% of the resulting gas and is separated from this hydrogen by condensation in liquid air. A second hydride, Sn_2H_2, is said to be produced as a grey powder by immersing aluminium foil in an alkaline solution of potassium stannite

Analysis.—Tin compounds when heated on charcoal with sodium carbonate or potassium cyanide in the reducing blowpipe flame yield the metal and a scanty ring of white SnO_2 Stannous salt solutions yield a brown precipitate of SnS with sulphuretted hydrogen, which is insoluble in cold dilute acids and in real sulphide of ammonium $(NH_4)_2S$; but the yellow, or the colourless reagent on addition of sulphur, dissolves the precipitate as a salt of SnS_2 The solution on acidification yields a yellow precipitate of this sulphide Stannic salt solutions give a yellow precipitate of SnS_2 with sulphuretted hydrogen, which is insoluble in cold dilute acids but readily soluble in sulphide of ammonium, and is re-precipitated therefrom as SnS_2 on acidification. Only stannous salts (not stannic) give a precipitate of calomel in mercuric chloride solution. A mixture of stannous and stannic chloride, when added to a sufficient quantity of solution of chloride of gold, gives an intensely purple precipitate of gold purple (purple of Cassius). The test is very delicate, although the colour is not in all cases a pure purple Tin is generally quantitatively estimated as the dioxide or electrolytically

PRODUCTION

Although deposits of tin are very widely distributed, the two areas which are of principal importance are the Asiatic deposits, comprising Malaya, Siam and China, and those of Bolivia. These two areas provide about 85% of the world's total output. Until 1916 the British Empire production exceeded that of foreign countries; but since that date, owing to the enlarged output from Bolivia and the Dutch East Indies, the production of other countries has been the larger. In 1925 the world's most important producer of tin was still the Federated Malay States where the alluvial deposits of the Kinta valley form the richest tinfield. The only tin-ore known in Malaya is the dioxide, cassiterite. The methods of working are ground sluicing and hydraulic mining, open cast-workings; underground workings and dredging In Burma the most important occurrences of tinstone are in the Bawlake State of Karenni, at the Mawchi Mines, in the Amherst district (*a*) at Belugyum, (*b*) east and west of the Seludang range; and in the Thaton, Tovoy and Mergui Districts.

The Burmese mineralized belt continues southwards through the F.M.S to the islands of Singkef, Banka and Billiton in the Dutch East Indies, thus forming the world's richest tin-producing area. In 1924 it supplied over 60% of the world's total output; and the Dutch East Indies alone contributed no less than 23·2% of the world's production. It was, however, stated in 1925 that within 12 years the bulk of the rich secondary deposits of Dutch East Indies, of Malaya, of Siam and of Lower Burma will have been exhausted. Other Asiatic occurrences of tin are those of French Indo-China in the province of Tongking; in China, in the provinces of Yunnan, Kwangsi, Hanan, Kwangtung and Fukien; and in Japan in (*a*) the Akenob district, Tajima province, (*b*) the Taniyama mine, Satsuma province, (*c*) the Kiura mine, Bungo province, (*d*) mines near Takayama and Hirukawa.

In North and central America cassiterite is known to occur in very small quantities, also in Canada, United States, Mexico and British Honduras. The most important producer in South America is Bolivia, whose tinfields supplied 21 4% of the world's total output in 1924. The chief mines occur in La Paz, Cochabamba, Oruro and Potosi. The most important point about the Bolivian deposits is that they are primary, and lode-mining is much more likely to yield larger outputs over a longer period of future years than is the case with the Asiatic deposits. Tin is widely distributed in Australasia—all the States of the Commonwealth of Australia and also New Zealand produce the mineral—but in 1923 the whole area yielded only 2½% of the world s total.

In the continent of Africa the most important tin producer is Nigeria. The tinstone occurs in the granites of the Younger Intrusive Series and in the tourmaline pegmatites of a somewhat earlier age. The pegmatites are found in all the crystalline areas of the Protectorate, but carry tinstone only in a few widely separated localities In the Transvaal, cassiterite occurs in pipe-like ore-bodies and veins in the Bushveld granite and overlying quartzites. In south-west Africa alluvial and detrital deposits have been worked hitherto, but many lodes occur and may be worked in future. In Swaziland tin-ore occurs both in alluvial deposits and veins. Most of the concentrates from Swaziland and the Union are shipped to the Straits Settlements for smelting. Other contributing countries are the Gold Coast, Nyassaland, Belgian Congo, Portuguese East Africa, South West Africa and Rhodesia. In 1924 the continent of Africa produced 5·47% of the world's production of tin for that year, mainly contributed by Nigeria.

In Europe the chief producing countries are Great Britain, Czechoslovakia, Germany, Portugal and Spain. With regard to the mines in Cornwall and Devon, during the 50 years ending 1800 the output varied between 2,000 and 3,500 tons a year. The maximum output during the World War was 6,537 in 1914. By 1922, when so few mines were working, the production was only 370 tons. By 1924, owing to the greatly improved conditions, the figure had risen to 1,725. In 1925 about 95% of the production occurred in the Camborne-Redruth area. Tin-smelting is an important industry in the United Kingdom, ores from Nigeria, Bolivia and other countries being treated in addition to domestic ores

The following table gives the world's production, in long tons, of tin ore for 1918, 1923 and 1925

	1918	1923	1925
Great Britain	3,954	1,021	2,339
Nigeria	5,004	5,860	6,256
Swaziland	358	107	277
Union of S. Africa	1,422	918	1,157
India (Burma)	647	1,400	1,300
Federation of Malay States	37,369	37,643	45,926
Unfederated Malay States	2,720	1,727	2,145
Australia	4,747	3,283	3,016
Approx total	57,100	52,000	62,600
Bolivia	29,104	29,767	32,074
Dutch East Indies	10,200	31,019	32,749
Siam	8,835	6,334	8,062
China	8,730	8,727	8,500
Other countries	226	1,740	2,000
Approx. total	66,100	78,600	83,400
World's total (approx)	123,200	130,600	146,000

The 1924 total was approximately 137,860 long tons.

TINAMOU, the name of a group of birds peculiar to South America, having some superficial resemblances to the partridge.

A RUFOUS TINAMOU OF GUIANA

The elongated bill, small head and slender neck are diagnostic. The plumage is some shade of brown, variously barred with darker tints. The wings are short and rounded and the male incubates the highly-burnished eggs. They are exceedingly stupid but are excellent to eat. Over 60 species are recognized. They are considered a group of palaeognathine birds and form the family *Tinamidae*. The little tinamou (*Crypturus pileatus*) ranges from the Amazon to Mexico, while the rufous tinamou (*Phychotus rufescens*) inhabits southern Brazil and Paraguay.

TINDAL, MATTHEW (d. 1733), English deist, the son of a clergyman, was born at Beer Ferrers (Ferris), Devonshire, probably in 1653. He studied law at Lincoln college, Oxford, under the high churchman George Hickes, dean of Worcester; in 1678 he was elected fellow of All Souls college. About 1685 he became a Roman Catholic, but returned to the Church of England at Easter, 1688. His early works were an *Essay of Obedience to the Supreme Powers* (1694); an *Essay on the Power of the Magistrate and the Rights of Mankind in Matters of Religion* (1697); and *The Liberty of the Press* (1698). The first of his two larger works, *The Rights of the Christian Church associated against the Romish and all other priests who claim an independent power over it*, pt. i., appearing anonymously in 1706 (2nd ed., 1706; 3rd, 1707; 4th, 1709), is a forcible defence of

Erastianism. Author, publisher and printer were prosecuted, but this did not prevent the issue of a fourth edition and gave the author the opportunity of issuing *A Defence of the Rights of the Christian Church,* in two parts (2nd ed., 1709). The book was, by order of the House of Commons, burned, along with Sacheverell's sermon, by the common hangman (1710) It continued to be the object of denunciation for years, and Tindal scented in a pastoral letter by Dr. Gibson, bishop of London, a charge of having undermined religion and promoted atheism and infidelity. He replied in the anonymous tract, *An Address to the Inhabitants of London and Westminster* (2nd ed, 1730). In this tract he defends the deists, and anticipates here and there his *Christianity as Old as the Creation; or, the Gospel a Republication of the Religion of Nature* (London, 1730, 2nd ed., 1731; 3rd, 1732; 4th, 1733), which was regarded as the "Bible" of deism. He died at Oxford on Aug. 16, 1733.

TINEO, a town of Spain, in the province of Oviedo; on a tributary of the Narcea, among the northern outliers of the Cantabrian mountains, and on the high road from Cangas de Tineo to the Biscayan port of Cudillero Pop. (1920), 22,009. Mining, agriculture and stock-rearing are the principal industries.

TINGUIAN, a tribe of north Luzon, in the Philippines, of Malayo-Indonesian stock More brachycephalic, and probably belonging to a later wave of immigration than the Igorot (*q.v.*) group, and showing stronger traces of Indian influence on culture probably traceable to Sumatran origin. The same influence appears in rice-cultivation methods, and irrigated terraces are less elaborate than those of the Igorot, who do not use the buffalo Marriage restrictions are based on blood-relationship only, not on clan, and the polity is democratic. A Creator is believed in, and spirits of various functions good and bad, some of which inhabit guardian stones The home of the dead, where life goes on as on earth, is sometimes placed in a mountain. The dead are dried before burial. Mediums, usually female, communicate with spirits.

See Cole, *The Tinguian* (1922).

TINNÉ, ALEXANDRINE PETRONELLA FRANCINA (1839–1869), Dutch traveller in Africa, born at The Hague on Oct 17, 1839, was the daughter of Philip F. Tinné, a Dutch merchant who settled in England during the Napoleonic wars Her father died when she was five years old, leaving her the richest heiress in the Netherlands. After travelling in Norway, Italy and the East, and visiting Egypt, when she ascended the Nile to near Gondokoro, Miss Tinné left Europe again in 1861 for the Nile regions. Accompanied by her mother and her aunt, she set out from Cairo on Jan. 9, 1862. After a short stay at Khartum the party ascended the White Nile to a point above Gondokoro, and explored a part of the Sobat, returning to Khartum in November. Baron Theodor von Heuglin (*q v*) and Dr. H. Steudner having meantime joined the ladies at Khartum, the whole party set out in Feb 1863 for the Bahr-el-Ghazal

Ascending the Bahr-el-Ghazal the limit of navigation was reached on March 10 From Meshra-er-Rek a journey was made overland, across the Bahr Jur and south-west by the Bahr Kosango, to Jebel Kosango, on the borders of the Niam-Niam country. During the journey all the travellers suffered severely from fever. Steudner died in April and Madame Tinné in June, and after many fatigues and dangers the remainder of the party reached Khartum in July 1864, where Miss Tinné's aunt died Miss Tinné returned to Cairo by Berber and Suakin In Jan. 1869 she started from Tripoli with a caravan, intending to proceed to Lake Chad, and thence to the upper Nile On Aug 1, however, on the route from Murzuk to Ghat, she was murdered, together with two Dutch sailors, by Tuareg who believed that her iron water tanks were filled with gold

See John A. Tinné's *Geographical Notes of an Expedition in Central Africa by three Dutch Ladies* (Liverpool, 1864), and Sir H. H. Johnston, *The Nile Quest,* ch. xvi. (London, 1903).

TINNED FOODS: *see* FOOD PRESERVATION.

TINNEVELLY, a town and district of British India, in the Madras presidency. The town is on the left bank of the Tambraparni river, on the other side of which is Palamcottah, the administrative headquarters of the district. Pop. (1921) 53,783. It is on the South Indian railway, 444 m. S.W. of Madras. A branch line was opened to Tiruchendur in 1923. Its most noteworthy building is a beautifully sculptured temple of Siva.

The DISTRICT OF TINNEVELLY has an area of 4,325 sq m. It is for the most part a plain with an average elevation of 200 ft., sloping to the east with slight undulations. It is watered by numerous short streams, the principal being the Tambraparni with a length of 80 m The chief irrigation work is the Srivaikuntam anicut or dam on this river. In the north the scenery is unattractive and the soil poor; in the south red sandy soil prevails in which little save the Palmyra palm will grow. This palm yields toddy as well as a coarse sugar. Along the banks of the rivers are rice-fields, cotton, millet, pulse and oil-seeds are grown, and cloth, mats, lace and sugar manufactured There is a trade in cotton stuffs, and fishing is carried on. The district contains many ancient and magnificent buildings. In 1921 the population was 1,901,396. The number of Christians was 192,350, Tinnevelly being the most Christian district in India. The Society for the Propagation of the Gospel and the Church Missionary Society have important stations at Tinnevelly town and Palamcottah, as also have the Jesuits It was here that St Francis Xavier began his preaching in India

The early history of Tinnevelly is mixed up with that of Madura and Travancore. Down to 1781 it is a confused tale of anarchy and bloodshed. In that year the nawab of Arcot assigned the revenues to the East India Company, which then undertook the internal administration Several risings subsequently took place, and in 1801 the whole Carnatic, including Tinnevelly, was ceded to the British

TIN-PLATE AND TERNE-PLATE. Tin-plate is a sheet of iron or steel which has been thinly coated with tin by being dipped in a molten bath of that metal Terne-plate is a sheet of iron or steel coated with a lead-tin alloy containing about 85% lead and 15% tin. The word terne was applied to this plate because of its dull appearance due to the large proportion of lead in the coating. The purpose of the tin in terne-plate coating is to act as a binder between the lead and the iron, which do not alloy

There are two processes for tinning In the "palm-oil" process, which is the older, the plates, after being properly annealed, are scoured with sand and water and pickled in dilute sulphuric acid alternately until they are perfectly clean and bright They are then washed in water, and after being boiled in palm oil to remove all traces of acid and water are dipped into a bath of molten tin covered with oil to prevent oxidation. They are then taken to a second bath containing purer tin than the first. After this they are scoured with a hempen rubber and dipped in a third bath containing the purest tin of all; then they are passed through rolls to finish the surface and regulate the thickness of the coating In the "acid process" only a single bath of tin is required The molten metal is covered with a layer of muriate of zinc, which acts as the flux, and by means of rolls the plates are passed through this down into the tin, to be brought out at another point in the bath where there is a layer of oil on the surface

The process of coating terne-plate is very similar to the galvanizing (*q v*) process The sheets, after having been pickled, are placed in the same kind of an acid solution, except the acid is somewhat weaker. The sheets first pass into a neutralized solution of zinc chloride. This flux enables the lead-tin mixture to adhere better to the base metal. Burners located under the intake side of the "kettle" keep its temperature at about 700 to 725° F The metal passes through the lead-tin alloy, under the flux, at the bottom of the kettle As the sheets emerge through the exit rolls, they pass through palm oil The rolls serve to pull the sheets through, and, together with the oil, they wipe off the excess metal and produce a smooth coating. This entire process is now completed by one machine; formerly it was necessary to dip and redip the sheets by hand Tongs are used to push the sheets down through the flux box until they are gripped and pulled out by the rolls. As the sheets leave the oil bath, an air spray cools them. They then pass through a set of flannel disk rolls that squeeze off the excess oil, and on to a conveyor They pass from the conveyor to cleaning machines, consisting of flannel disk rolls and

brushes, using sawdust, peanut hulls, meal or bran further to absorb and to clean off the oil The weight of coating is more difficult to control than it is in galvanizing It is affected by the heat of the bath. speed of the machine, the kind of rolls used and the surface of the sheet coated The temperature limits of the operation are very narrow.

The sheets employed in the manufacture of tin-plate and terneplate are known as "black plates" Formerly iron alone was used, and was of two grades, coke-iron and charcoal-iron, the latter being the better, received a heavier coating of tin, and this circumstance is the origin of the terms "coke-plates" and "charcoal plates" by which the quality of tin-plate is still designated Later steel was used but it was found that iron plate was more durable. Now both iron and steel plates are available. (*See* SHEETS, IRON AND STEEL.) It has been attempted to lower the price of terneplate by using coatings entirely too light Although much of this light-coated terne-plate is still used, high grade plate, properly coated, is obtainable. The service pure iron renders will, no doubt, cause more and more of this product to be used as the base for terne roofing plate as well as long ternes Two different types of finishes are obtainable; "bright dry" or "dark oil" These different effects are imparted as it travels through the machine

Long ternes are similar to terne-plates except that the sheets are larger, and the tin content usually runs about 12½%. The lead in the lead-tin alloy makes long terne-plate ideal for fabrication into caskets, automobile gasolene tanks and other products in the manufacture of which deep drawing and stamping (*see* PRESSED METAL) is necessary. The lead serves as a lubricant in forming operations, causing the sheets to flow uniformly under the dies. (B CHA)

TIN PRINTING: *see* LITHOGRAPHY

TINTAGEL (tĭn-tăj'ĕl) or **TREVENA,** village, Cornwall, England, 4½ m N W. of Camelford Pop (1921) 1,307. It stands on a bare upland, close to the sea; and below it is Tintagel Haven, or Porth, a small cove surrounded by cliffs of almost black slate Ruins of a castle are built partly on the mainland, partly on a rugged promontory, Tintagel Head, united by a narrow peninsula to the shore The Norman walls are so darkened and weathered that, from a little distance, they seem a part of the rock itself The cruciform parish church of St Marcelliana stands on a high cliff, west of the castle Although restored, it retains traces of Saxon workmanship in the chancel, besides two Norman doorways, a font of the same period, a stone altar bearing five crosses and a fine 15th-century brass In the churchyard the graves are buttressed, storms being frequent and violent. For a time the church belonged to Fontevrault abbey in Normandy; but it was made over by Edward IV to the collegiate church of Windsor. A 9th-century roodstone stands in the village. Portions of the vicarage date from the 14th century.

Tintagel (Tintajol, Dundagel) is a parish a portion of which appears in the Domesday Survey as Bossincy (Botcinnu). The castle probably existed in pre-Saxon times, and under the Norman earls of Cornwall was rebuilt, embattled and furnished with munitions of war It was in a ruinous condition in Leland's time (*c.* 1540). The borough of Bossiney, which apparently owed its existence to the castle, shared its fortunes. Its charter was surrendered to Charles II and a new one obtained from his brother in 1685 Provision was made for the administration of the borough. Bossiney acquired the right of electing two members of parliament in 1553. In 1784 the vicar of Tintagel, as mayor and only qualified elector, enjoyed the probably unique privilege of returning two members to the House of Commons. In 1832 there were ten resident legal voters within the borough and nine out-voters. The Reform Act transferred their votes to the county.

TINTERN ABBEY, in Monmouthshire, one of the most famous ecclesiastical ruins in England, on the River Wye. The abbey was founded by Walter de Clare in 1131 for Cistercian monks. The existing church, however, dates from the latter part of the 13th century; it is unroofed, and the nave is imperfect, but many of the finest details of a style transitional from Early English to Decorated are preserved. The church is cruciform. Cloisters and other monastic buildings, of which there are considerable remains, lay to the north of the church. The foundation was dissolved by Henry VIII.

TINTOMETER, a commercial instrument which makes it possible to register colours (*e.g.*, of oils) by matching them against the light transmitted by one or more of a set of coloured glasses, each glass being of a slightly different tint from those on either side of it in the set. (*See* COLOUR)

TINTORETTO, JACOPO ROBUSTI (1518–1594), one of the greatest painters of the Venetian school, was born in Venice in 1518, though Ridolfi says in 1512. His father, Battista Robusti, was a dyer, or "tintore", hence the son got the nickname of "Tintoretto," little dyer. His father, noticing his artistic bent, took him to the studio of Titian. Ridolfi is our authority for saying that Tintoretto had only been ten days in the studio when Titian sent him home once and for all. The reason, according to the same writer, is that the great master observed some very spirited drawings by the boy and it is inferred that he became at once jealous of so promising a scholar. This, however, is mere conjecture. From this time forward the two always remained upon distant terms—Robusti being indeed a professed and ardent admirer of Titian, but never a friend, and Titian turning the cold shoulder to Robusti, who sought for no further teaching, but studied on his own account with laborious zeal from casts, bas-reliefs etc. He placed over his studio the inscription "Il disegno di Michelangelo ed il colorito di Tiziano" (Michelangelo's design and Titian's colour) He is said to have studied more especially from models of Michelangelo's "Dawn," "Noon," "Twilight" and "Night," and from Sansovino's statues, and to have modelled in wax and clay small figures, which he suspended in a box with an aperture for a candle Thus, according to Ridolfi, Robusti's art was self-taught. More recent criticism, however, has averred that he probably proceeded to some other painter's studio on leaving Titian's Berenson and Thode have suggested that Bonifazio may have been his master while Hadeln thinks Bordone more likely However, he had a hard struggle to obtain recognition He assisted Schiavone in his studio and undertook every commission which offered itself One of Tintoretto's early pictures still extant is in the church of the Carmine in Venice, the "Presentation of Jesus in the Temple" In 1547 he painted the "Last Supper" in the Church of S Marcuola. The "Christ Washing the Apostles' Feet" painted for the same church is now in the Escorial. For the Scuola della Trinità he painted four subjects from Genesis Two of these, now in the Venetian Academy, are "Adam and Eve" and the "Death of Abel," both noble works of high mastery, which leave us in no doubt that Robusti was a consummate painter

In 1548 he was commissioned for four pictures in the Scuola di S. Marco—the "Finding of the body of St Mark in Alexandria" (now in the Brera, Milan), the "Saint's Body brought to Venice," the "miraculous preservation of a Saracen sailor at sea by the Saint" (these two are in the library of the royal palace, Venice), and the highly and justly celebrated "Miracle of the Slave." These works were greeted with general applause, including that of Titian's intimate, the too potent Pietro Aretino The painter's straits and obscure endurances were over. He married Faustina de' Vescovi, daughter of a Venetian nobleman, and settled in a house in the Fondamenti de Mori near the church of the Madonna dell' Orto. Here he painted three of his leading works—"The Worship of the Golden Calf," "The Presentation of the Virgin" and the "Last Judgment"

The next conspicuous event in the professional life of Tintoretto is his enormous labour and profuse self-development on the walls and ceilings of the Scuola di S. Rocco, a building which may now almost be regarded as a shrine reared by Robusti to his own genius. The building had been begun in 1524 by Sante Lombardi, after the design of Bart. Buono and was very deficient in light, so as to be particularly ill-suited for any great scheme of pictorial adornment. The painting of its interior was commenced in 1560. In that year five principal painters, including Tintoretto and Paul Veronese, were invited to send in trial-designs for the centre-piece in the smaller hall named Sala dell' Albergo, the subject being S. Rocco received into Heaven. Tintoretto produced not a sketch but

a picture, and got it inserted into its oval. The competitors remonstrated, not unnaturally; but the artist, who knew how to play his own game, made a free gift of the picture to the saint, and, as a by-law of the foundation prohibited the rejection of any gift, it was retained *in situ*—Tintoretto furnishing gratis the other decorations of the same ceiling. (This is one version of the anecdote. there is another version, which has the like general bearing.) In 1565 he resumed work at the scuola, painting the magnificent "Crucifixion," for which a sum of 250 ducats was paid In 1576 he presented gratis another centre-piece—that for the ceiling of the great hall, representing the "Plague of Serpents"; and in the following year he completed this ceiling with pictures of the "Paschal Feast" and "Moses striking the Rock." Robusti next launched out into the painting of the entire scuola and of the adjacent church of S Rocco. He offered in November 1577 to execute the works at the rate of 100 ducats per annum, three pictures being due in each year. This proposal was accepted and was punctually fulfilled, the painter's death alone preventing the execution of some of the ceiling-subjects. The whole sum paid for the scuola throughout was 2,447 ducats. Disregarding some minor performances, the scuola and church contain fifty-two memorable paintings, which may be described as vast suggestive sketches, with the mastery of finished pictures, "Adam and Eve," the "Visitation," the "Adoration of the Magi," the "Massacre of the Innocents," the "Agony in the Garden," "Christ before Pilate," "Christ carrying His Cross" and the "Assumption of the Virgin" are leading examples in the scuola; in the church, "Christ curing the Paralytic"

It was probably in 1560, the year in which he began working in the Scuola di S Rocco, that Tintoretto commenced his numerous paintings in the ducal palace, he then executed there a portrait of the doge, Girolamo Priuli Other works which were destroyed in the great fire of 1577 succeeded—the "Excommunication of Frederick Barbarossa by Pope Alexander III." and the "Victory of Lepanto" After the fire Tintoretto started afresh, Paul Veronese being his colleague In the Sala dello Scrutinio Robusti painted the "Capture of Zara"; in the hall of the senate, "Venice, Queen of the Sea" and two others; in the Sala del Collegio 4 pictures among which the "Espousal of St. Catherine"; in the Sala dell' Anticollegio, four decorative masterpieces—"Bacchus, with Ariadne crowned by Venus," the "Three Graces and Mercury," "Minerva discarding Mars," and the "Forge of Vulcan"—which were painted towards 1578; in the Antichiesetta, "St George and St. Louis, with St Margaret," and "St. Jerome and St. Andrew"; in the hall of the great council, nine large compositions, chiefly battle-pieces. We here reach the crowning production of Robusti's life, the last picture of any considerable importance which he executed, the vast "Paradise," in size 74 ft. by 30, reputed to be the largest painting ever done upon canvas. It is a work so stupendous in scale, so colossal in the sweep of its power, so reckless of ordinary standards of conception, so pure an inspiration of a soul burning with passionate visual imagining and a hand magical to work in shape and colour, that it has defied the connoisseurship of three centuries, and has generally (though not with its first Venetian contemporaries) passed for an eccentric failure All Venice applauded the superb achievement Robusti was asked to name his own price, but this he left to the authorities Robusti died on May 31, 1594. The register of deaths in S. Marciliano states that Tintoretto died of fever, aged seventy-five years, eight months and fifteen days—thus bringing us to Sept. 16, 1518 as the true date of his birth. He was buried in the church of the Madonna dell' Orto by the side of his favourite daughter Marietta (*c.* 1556–1590?) who had herself been a portrait-painter of considerable skill, as well as a musician, vocal and instrumental. In 1866 the grave was opened, and the remains were moved to the chapel on the right of the choir.

Tintoretto painted his own portrait at least twice (Uffizi, Florence and Louvre, Paris). It is a face somewhat blunt and rugged, but yet refined—concentrated and resolute, its native ardours of frankness and energy welded down into lifelong laboriousness, with a pent look as of smouldering fire. The eyes are large, dark and round; the grizzled hair close and compact.

In 1574 he obtained the reversion of the first vacant broker's patent in a fondaco, with power to bequeath it—an advantage granted from time to time to pre-eminent painters. For his phenomenal energy in painting he was termed "Il Furioso." An agreement is extant showing that he undertook to finish in two months two historical pictures each containing twenty figures, seven being portraits. The number of his portraits is enormous; their merit is unequal, but the really fine ones cannot be surpassed. The Venetians said that he had three pencils—one of gold, the second of silver and the third of iron. The only pictures (if we except his own portrait) on which he inscribed his name are the "Miracle of Cana" in the church of the Salute (painted originally for the brotherhood of the Crociferi), the "Miracle of the Slave," and the "Crucifixion" in the Scuola di S Rocco; the last was engraved in 1589 by Agostino Caracci

Of pupils Robusti had very few, his two sons and Martin de Vos of Antwerp were among them Domenico Robusti (1560–1635) whom we have already had occasion to mention, frequently assisted his father in the groundwork of great pictures. Some of his works are to be seen in the academy at Venice and in S Maria degli Angeli at Murano.

We conclude by naming a few of the more striking of Tintoretto's very numerous works not already specified in the course of the article In Venice (S Giorgio Maggiore), a series of his later works, the "Gathering of the Manna," "Last Supper," "Entombment," "Resurrection"; (S Cassiano) a "Crucifixion," the figures seen from behind along the hill slope; (St Mark's) a mosaic of the "Baptism of Christ." In Milan (the Brera), "St Helena and other saints." In Florence (Uffizi) three fine portraits including that of the sculptor Jac Sansovino, (Pitti Gallery), "Venus," "Vulcan" and "Cupid." In Dresden "The Rescue" In Cologne (Wallraff-Richarts Museum), "Ovid and Corinna" In Munich (Pinakothek) eight paintings executed (1579–1580) for the Duke of Mantua, illustrating historical scenes—one of the siege of a fortified town is astonishingly fine In England (Hampton Court), "Esther and Ahasuerus," and the "Nine Muses"; (the National Gallery), "The Origin of the Milky Way," a memorable *tour de force*, "Christ washing Peter's Feet," also a spirited smallish work, "St George and the Dragon" A fine portrait of a Doge has recently been acquired by the Melbourne Gallery from Prince Lichnowski's collection In the Ca d'oro museum, Venice, are a number of distinguished portraits of Venetian Senators Tintoretto's unparalleled mastery of the human form is revealed in his drawings of which a volume has recently been published (D. von Hadeln, *Handzeichnungen des Tintoretto*, 1922)

Meyer, *Jacopo Tintoretto* (Munich 1923). (W M R; X)

TIPASA, a town and commune on the coast of Algeria, in the department of Algiers, 30 m W of the capital The modern village (pop 753, of which 618 are Europeans), founded in 1857, is remarkable chiefly for its pleasant situation and sandy beach The roadstead is exposed to the north-east and north-west There is a mole about 90 ft long and anchorage in six fathoms The Roman city of Tipasa was built on three small hills which overlooked the sea. Of the houses, most of which stood on the central hill, no traces remain; but there are ruins of three churches—the Great Basilica and the Basilica Alexander on the western hill, and the Basilica of St. Salsa on the eastern hill—two cemeteries, the baths, theatre, amphitheatre and nymphaeum.

Tipasa was founded by the Phoenicians, was made a Roman military colony by the emperor Claudius, and afterwards became a municipium Christianity was early introduced, and in the third century Tipasa was a bishop's see. In 484 the Vandal king Huneric (477–484) sent an Arian bishop to Tipasa; whereupon a large number of the inhabitants fled to Spain, while many of the remainder were cruelly persecuted. After this time the city disappears from history.

See S Gsell, *Promenades archéologiques aux environs d'Alger* (1926);

TIPPERA, a district of British India, in the Chittagong division of Bengal. Area, 2,560 sq m ; pop. (1921) 2,743,073. The administrative headquarters are at Comilla (pop. 25,914). The district has a flat and open surface, with the exception of the isolated Lalmai hills (100 ft), and is for the most part laid out in well-cultivated fields, intersected by rivers and creeks. The principal rivers are the Meghna, or estuary of the Brahmaputra, the Gumti, Dakatia and Titas

Tippera formed part of the Tripura State (*q v.*) till 1733 when it was conquered and annexed to the Mogul empire by the nawal of Bengal When it came under the East India company in 1765, more than a fifth of its present area was under the immediate rule of the raja of Tripura, who paid a tribute of ivory and elephants Since then nothing has disturbed the peace of the district with the exception of a serious raid in 1860 by the Kukis or Lushais, who burnt down 15 villages, killed 185 persons, and carried off 100 prisoners

TIPPERARY, a county of Ireland in the province of Munster, bounded north-west by Galway, north-east by Offaly County, east by Leix County and Kilkenny, south by Waterford, and west by Cork, Limerick, Clare and Galway The county is the sixth in size of the Irish counties, having an area of 1,062,963 acres, or about 1,661 sq m Pop (1926) 140,946 Sandstone heights stand out above the limestone plain The Knockmealdown Mountains on the southern border reach an elevation of 2,609 ft To the north of this range are the Galty or Galtee Mountains (Galtymore 3,015 ft) To the east, bordering Kilkenny, are the Slievear-dagh Hills, and near Templemore the Devil's Bit Mountains (1,583 ft) with a curious gap on the summit In the north-west is Keeper Hill, 2,278 ft The folded character of the Carboniferous limestone is seen in the anticlinal boss on which stands the acropolis of Cashel The Suir has its source in the Devil's Bit Mountains, and flows southward and eastward by Templemore, Thurles, Caher, and Clonmel The Nore, which also rises in the Devil's Bit Mountains, soon passes into Leix County, and the Shannon forms part of the western border The Mitchelstown stalactite caverns were discovered accidentally in 1833 They are in the extreme south-west of the county; take their name from the neighbouring town of Mitchelstown, 6 m distant in County Cork; and were explored by M Martel in 1895.

Tipperary is one of the counties generally considered to have been formed by King John in 1210; in 1328 Edward III made it a county palatine in favour of the earl of Ormonde; and, though the king shortly afterwards resumed his regal prerogative, the county was regranted in 1337 In 1372 the grant was confirmed to James Butler, earl of Ormonde, the lands belonging to the Church retaining, however, a separate jurisdiction, and being known as the county of Cross Tipperary, or the Cross of Tipperary In 1621 James I took the county palatine into his own hands It was, however, restored in 1664 to James, 12th earl and 1st duke, whose regalities were further made to include the county of the Cross. On the attainder of James, 2nd duke, in 1715, the jurisdiction reverted to the Crown, and the last Irish palatinate thus ended.

The subsoil in the lower grounds is limestone, which is overlaid by a rich calcareous loam. The Golden Vale, the most fertile district in Ireland, stretches from Cashel to the town of Limerick. There is some mining The lead ore mined for many centuries at Silvermines south of Nenagh is silver-bearing, and is associated with zinc blende Indications of ore have been traced along the junction of the limestone with the older rocks Good slates are quarried in the Silurian area in Clashnasmuth townland on Slieve-naman There is a considerable number of meal and flour mills.

Communications are supplied by the Great Southern railway, the main line of which crosses the county from north-east to south-west by Templemore and Thurles The Ballybrophy (Leix County) and Limerick branch from this line serves the north of the county by Roscrea (junction for Birr) and Nenagh The Waterford and Limerick line passes through the south of the county by way of Clonmel and Tipperary, crossing the main line at Limerick Junction. The two lines are also connected by the Thurles, Fethard and Clonmel branch.

The county will benefit considerably from the electricity power stations in process of construction along the lower Shannon.

The administrative Counties of Tipperary North Riding and Tipperary South Riding together return 7 members to Dáil Eireann.

TIPPERARY, a town of Co. Tipperary, Ireland, near the Slieve na muck or Tipperary hills, a branch of the Galtee range, on the Great Southern railway, 3 m. S E of Limerick Junction and 110¼ S.W of Dublin Pop. (1926) 5,554. Its butter market ranks next to that of Cork. Condensed milk is manufactured. The town first acquired importance through the erection of a castle by King John, of which there are no remains A monastery founded for Augustinians by Henry III. gave a second impulse to its growth The gatehouse is all that remains of this foundation. Formerly Tipperary was a corporation from a grant made in 1310 by Edward II. New Tipperary was founded outside the town in 1890.

TIPPOO SAHIB (1753–1799), sultan of Mysore, son of Hyder Ali (*q.v*), was born in 1753. He was instructed in military tactics by French officers in the employment of his father. In 1767 in the invasion of the Carnatic he commanded a corps of cavalry, and fought in the Mahratta War of 1775–79. On the outbreak of the first Mysore War in 1780 he was put at the head of a large body of troops, and defeated Brathwaite on the banks of the Coleroon in Feb 1782. He succeeded his father in Dec. 1782, and in 1784 concluded peace with the British, and assumed the title of sultan. In 1787–88 he subjugated the Nairs of Malabar, and in 1789 provoked British invasion by ravaging the territories of the raja of Travancore When the British entered Mysore in 1790, he retaliated by a counter-invasion, but was compelled by Cornwallis's victory near Seringapatam to cede half his dominions (March 16, 1792) When the British renewed hostilities in March 1799, he was shut up in Seringapatam and finally killed during the storming (May 4, 1799).

See L B Bowring, *Haidar Ali and Tipu Sultan* (1893).

TIPTON, an urban district in the Wednesbury parliamentary borough, Staffordshire, England, 1½ m N of Dudley, served by the L M S and G W. railways Pop (1921), 34,130 It has important coal mines and ironworks, numerous furnaces and rolling mills. Its principal products are heavy iron goods, including anchors and cables. The modern town sprang up round Tibbington, mentioned in Domesday.

TIRAH, a mountainous tract of country on the Peshawar border of the North-west Province of India. It lies between the Khyber pass and the Khanki valley, and is inhabited by the Afridi and Orakzai tribes It is chiefly notable as the scene of the Tirah Campaign of 1897 It is a cul-de-sac in the mountains, lying off all the roads to India, and comprises an area of some six to seven hundred square miles and includes the valleys lying round the source of the Bara river. The five chief valleys are Maidan, Rajgul, Waran, Bara, Mastura The chief passes are Sampagha pass (6,500 ft), separating the Khanki valley from the Mastura valley; the Arhanga pass (6,995 ft), separating Mastura valley from Maidan, Saran Sar (8,650 ft), leading from the Zakka Khel portion of Maidan into the Bara valley; the Tseri Kandao (8,575 ft.), separating Maidan from the Waran valley, and the Sapri pass (5,190 ft.), leading from the east of the Mastura valley into the Bara valley in the direction of Mamanai. The whole of Tirah was thoroughly explored and mapped at the time of the Tirah campaign.

Tirah Campaign, an Indian frontier war in 1897–98. The Afridis had for 16 years received a subsidy from the Indian Government for the safeguarding of the Khyber pass, in addition to which the Government had maintained for this purpose a local regiment entirely composed of Afridis, who were stationed in the pass. Suddenly, however, the tribesmen rose, captured all the posts in the Khyber held by their own countrymen, and attacked the forts on the Samana ridge near Peshawar. It was estimated that the Afridis and Orakzais could, if united, bring from 40,000 to 50,000 men into the field. The preparations for the expedition occupied some time, and meanwhile the Mohmand rising north-west of the Khyber pass was first dealt with (*see* MOHMAND).

The general commanding was Gen. Sir William Lockhart (*q v.*), commanding the Punjab army; he had under him 34,882 men, British and native, in addition to 20,000 followers. The frontier post of Kohat was selected as the base of the campaign, and it was decided to advance along a single line On Oct. 18 the operations commenced, fighting ensuing immediately The Dargai heights, which commanded the line of advance, were captured without difficulty, but abandoned owing to the want of water. On the 20th the same positions were gallantly stormed by the Gordon Highlanders and 3rd Sikhs, with a loss of 199 killed and wounded. The progress of the expedition, along a wretched track through the mountains, was obstinately contested on Oct. 29 at the Sampagha pass leading to the Mastura valley, and on the 31st at the Arhanga pass from the Mastura to the Tirah valley. The force, in detached brigades, now proceeded to traverse the Tirah district in all directions, and to destroy the walled and fortified hamlets of the Afridis. The two divisions available for this duty numbered about 20,000 men. A force about 3,200 strong, commanded by Brig -Gen. Westmacott, was first employed to attack Saran Sar, which was easily carried, but during the retirement the troops were hard pressed by the enemy and the casualties numbered sixty-four On Nov. 11 Saran Sar was again attacked by the brigade of Brig -Gen. Gaselee Experience enabled better dispositions to be made, and the casualties were only three The traversing of the valley continued, and on Nov. 13 Brig -Gen Kempster's brigade visited the Waran valley via the Tseri Kandao pass Little difficulty was experienced during the advance, and several villages were destroyed; but on the 16th, during the return march, the rearguard was hotly engaged all day and had to be relieved by fresh troops next morning The casualties numbered seventy-two. Almost daily the Afridis, too wise to risk general engagements, waged a perpetual guerrilla warfare, and the various bodies of troops engaged in foraging or survey duties were constantly attacked On Nov 21 a brigade under Brig -Gen Westmacott was detached to visit the Rajgul valley The road was exceedingly difficult and steady opposition was encountered The objects were accomplished, and the casualties during the retirement alone numbered twenty-three The last important work undertaken was the punishment of the Chamkannis, Mamuzais and Massozais. This was carried out by Brig -Gen Gaselee, who joined hands with the Kurram movable column ordered up for the purpose The Mamuzais and Massozais submitted immediately, but the Chamkannis offered resistance on Dec 1 and 2, the British casualties numbering about thirty The Kurram column then returned to its camp, and Sir W Lockhart prepared to evacuate Tirah, despatching his two divisions by separate routes—the 1st under Maj -Gen. W. Penn Symons to return via the Mastura valley, destroying the forts on the way, and to join at Bara, within easy march of Peshawar, the 2nd division under Maj.-Gen. Yeatman Biggs, and accompanied by Sir W. Lockhart, to move along the Bara valley. The base was thus to be transferred from Kohat to Peshawar. The return march began on Dec 9 The cold was intense, 21 degrees of frost being registered before leaving Tirah The movement of the 1st division though arduous was practically unopposed, but the 40 miles to be covered by the 2nd division were contested almost throughout The actual march down the Bara valley (34 miles) commenced on the 10th, and involved four days of the hardest fighting and marching of the campaign The road crossed and recrossed the icy stream, while snow, sleet and rain fell constantly On the 10th the casualties numbered about 20. On the 11th some 50 or 60 casualties were recorded among the troops, but many followers were killed or died of exposure, and quantities of stores were lost On the 12th the column halted for rest. On the 13th the march was resumed in improved weather, though the cold was still severe The rearguard was heavily engaged, and the casualties numbered about sixty. On the 14th, after further fighting, a junction with the Peshawar column was effected. The 1st division, aided by the Peshawar column, now took possession of the Khyber forts without opposition Negotiations for peace were then begun with the Afridis, who, under the threat of another expedition into Tirah in the spring, at length agreed to pay the fines and to surrender the rifles demanded. The expeditionary force was broken up on April 4, 1898. A memorable feature of this campaign was the presence in the fighting line of the imperial service native troops under their own officers, while several of the best known of the Indian princes served on Sir W. Lockhart's staff. (C. J B)

TIRANA, the capital of Albania, lies at the southern end of the plain of Kroya (Albanian, *Kruja*). Pop. (1924) about 18,000, including the troops, the civilians numbering only 3,600. Nearly three-quarters of the total are Muslims, and the remainder divided between Orthodox and Roman Catholics. Tirana is beautifully situated at the foot of the richly wooded highlands inhabited by the Mirdite Albanians It is a picturesque town, with many mosques, gardens and olive groves.

Tirana was founded early in the 17th century, and was long the seat of a Greek bishop, although the majority of its inhabitants are Muslims.

TIRARD, PIERRE EMANUEL (1827–1893), French politician, was born of French parents at Geneva on Sept 27, 1827. In 1869 he was elected mayor of the 11th arrondissement of Paris and deputy for the Seine. In 1871 he sat among the extreme Left in the National Assembly at Versailles. In 1876 he was returned for the 1st arrondissement of Paris to the Chamber of Deputies He held office in a series of ministries between 1870 and 1885, and when Carnot became president of the Republic in 1887 he asked Tirard to form a ministry. He had to deal with the Wilson scandal which had led to President Grévy's downfall, and with the revisionist agitation of General Boulanger His refusal to proceed to the revision of the constitution of 1875 led to his defeat on March 30, 1888. He returned to power next year, and decided to bring Boulanger and his chief supporters before the High Court, but Boulanger fled. He also arrested Philip, duke of Orleans, who had visited France in disguise He resigned office on March 15, 1890 on the question of the Franco-Turkish commercial treaty He replaced M. Rouvier in the Ribot cabinet (1892–1893) as minister of finance, and died in Paris on Nov 4, 1893

TIRE (RUBBER) MANUFACTURE: *see* TYRE.

TIRHUT, a division of British India, in Behar and Orissa, situated between Nepal and the Ganges. The name was formerly applied only to a single district, which in 1873 was divided into the two districts of Darbhanga and Muzaffarpur In 1908 the four northern districts of Darbhanga, Muzaffarpur, Saran and Champaran were detached from the Patna division and formed into a new division, to which the name of Tirhut was officially given Total area, 12,598 sq m ; total pop (1921), 9,949,268 It is a continuous alluvial plain, traversed by many rivers and supporting a dense population Tirhut is a corruption of Tirabhurti, meaning the river-side country, a name which has been found on seals of the 4th or 5th century A D, discovered at Basarh in Muzaffarpur district. In its present limits it corresponds roughly with the ancient kingdom of Mithila (*q v.*)

TIRIDATES or TERIDATES, a Persian name, given by Arrian in his *Parthica* (preserved by Photius, *cod.* 58, and Syncellus, p 539 *seq*) to the brother of Arsaces I , the founder of the Parthian kingdom, whom he is said to have succeeded. But Arrian's account seems to be quite unhistorical. (*Cf* PARTHIA)

The king commonly called TIRIDATES II. was set up by the Parthians against Phraates IV. in 32 B C., but expelled when Phraates returned with the help of the Scythians (Dio Cass li 18; Justin xlii. 5 *seq.; cf.* Horace, *Od.* i. 26). Tiridates fled to Syria, where Augustus allowed him to stay, but refused to support him. During the next years Tiridates invaded Parthia again; some coins dated from March and May, 26 B C, with the name of a king "Arsaces Philoromaios," belong to him; on the reverse they show the king seated on the throne, with Tyche stretching out a palm branch towards him. He was soon expelled again, and brought a son of Phraates into Spain to Augustus. Augustus gave the boy back to his father, but declined to surrender "the fugitive slave Tiridates" (Justin xlii. 5; Dio liii. 33; cf *Mon. Ancyr.* 5, 54; in li. 18 Dio wrongly placed the son's surrender in 30 B.C).

TIRIDATES III , grandson of Phraates IV , lived as a hostage in Rome and was educated there When the Parthians rebelled against Artabanus II in A D. 35 they applied for a king to

Tiberius, who sent Tiridates. With the assistance of L. Vitellius Tiridates entered Seleucia, but could not maintain himself long (Tacitus, *Ann.* vi. 32 *sqq.;* Dio Cass lviii 26). (Ed. M)

TIRLEMONT (Flemish *Thienen*), a town in the province of Brabant, Belgium, 11 m. S E of Louvain Pop. (1925) 20,346. It still preserves its enceinte, 6 m in circumference The principal church, Notre Dame du Lac, begun in the 12th century and enlarged in the 15th, is still unfinished The church of St. Germain, also 12th century, contains a fine altar-piece by Wappers.

TIRMIDHI [Abū 'Isā Mohammed ibn 'Isā ut-Tirmidhi] (d 892), Arabian traditionalist, was born at Tirmidh on the Jiḥūn He travelled through Khurasan, Iraq and Hejaz His *al-Jāmi' us-Ṣaḥīh* (published at Bulaq, 1875) is one of the six canonical collections of traditions. He included every tradition that had ever been used to support a legal decision He also wrote the *Kitāb ush-Shama'il* (printed at Calcutta, 1846) on the character and life of Mohammed

TIROL, an Austrian province comprising an area of 4,882 sq.m of almost wholly mountainous country elongated in an east-west direction to which rock formations and human activities are also oriented Three distinct lithological belts exist The northern third of the province is a limestone zone, including the Lechtal and N Tirol Alps, which forms a series of parallel ranges that sink from heights exceeding 9,000 ft (Parseier Spitz—9,963 ft) northwards and eastwards The porosity of this rock and the resultant steep slopes hinder tree growth and cultivation, so that more than half is either poor pasture or barren land. Only on old glacial deposits in the valleys do conditions improve and the deep groove of the Inn valley is therefore a striking contrast Although the unifying thread of the human life of the province, it is throughout its longitudinal course a geological boundary and is floored with mixed débris derived from the flanking limestone to the north and the crystalline or schistose belts to the south. As a result there is on its alluvial fans and drained lower terraces an intensive cultivation, helped by the *fohn* winds, and a number of settlements; nevertheless, the chief interests of its inhabitants are pastoral In the cultivated districts maize, rye and fruit predominate in the west, rye and wheat in the lower valley.

South of the Inn valley, the twofold crystalline zone of the Central Alps appears, part granite and gneiss, part schist and slates, forming the main chain and including from west to east the glaciated Ötztal, Stubai and Zillertal Alps, and continues east of the transverse course of the river in the lower, unglaciated, slaty Kitzbühl Alps. In this zone *Almen* or summer mountain pastures, often above the tree line, dominate human life, 50% of the productive surface being so utilized, and numbers of cattle are exported to South Germany both for breeding and killing Horse breeding, too, is common, the favourite breed being the Noric type for farm and other hard work Forestry is not so important here as in the limestone zone where some 60% of the productive surface is forested, while, generally, methods are less scientific than elsewhere in Austria.

TOBLACHER SEA, IN THE VALLEY OF THE RIENZ, ONE OF THE MANY BEAUTIFUL LAKES IN TIROL

Industries.—Once an important mining centre for copper and rare metals, Tirol now raises only 1½% of the Austrian output Salt takes first place and is worked at Hall being conducted in the form of brine by a leat from the Salzberg, 5½ m. distant. The raising of lignite, zinc ores (Imst), and oil shale (Kufstein), and the preparation of cement (Lower Inn valley) complete the list of important mineral interests

In the development of manufactures Tirol is aided by its rich supplies of water power Large electrical power stations exist at Landeck, Matrei, Wiesberg, etc , in some cases associated with the extraction of aluminium and the preparation of calcium carbide. Cotton manufacturing has spread across from Vorarlberg (*q.v*) to the Western Tirol, woollen goods are important in Innsbruck and the Ziller valley, paper, wood pulp and cellulose works are found near and along the Inn, while small iron goods and metal wares are widely manufactured, the former in the Stuba valley. the latter principally at Innsbruck and Schwaz; in addition saw mills and breweries are widespread.

BOY IN TYPICAL COSTUME OF AUSTRIAN TIROL

Population.—The population of Tirol—314,836 (1923)—is almost entirely German in speech, Roman Catholic in religion and advanced in education, having at Innsbruck (*q v.*) one of the three universities of Austria The greatest density of settlement is found along the great longitudinal trade route of the Inn, with a concentration at Innsbruck, where it is crossed by the transverse route from Germany to Italy by the Brenner Pass. The limestone zone is very scantily peopled in contrast to the well-watered crystalline belt on which isolated farms and small towns in the valleys are more common The old isolation of these mountain valleys is fast disappearing under the swelling annual tide of tourists and, with its passage go many of the old customs and picturesque peculiarities of costume The province, like all others in the Federal Republic of Austria, has a large measure of local autonomy, centred at Innsbruck, but matters such as national defence, legal administration, foreign affairs, etc , are handled by the National parliament to which it sends representatives

HISTORY

In 15–14 B C the country, later known as the Tirol then inhabited by the Rhaetians (probably a Celtic race), was conquered by Drusus and Tiberius The frontier of Italy was then advanced to a line running approximately from Gargazon to the Klausen Pass, the country north of this being organized into the province of Rhaetia After 500 years of Roman rule, during which the country was probably almost completely Romanized, it fell a prey to the Teutonic invasions The rich valleys of the upper Adige were colonized by Ostrogoths, from whom the present inhabitants are descended A little later the Germanic Bajuvarii conquered and occupied the whole northern district, which was quickly Germanized The Lombards, who entered the country almost simultaneously from the south, establishing a duchy in Trent, came in smaller numbers, and were absorbed in the Latin population; from this difference sprang the later ethnographical and political controversy Lombardy became part of the Frank empire of the Carolingians in A D 774, Bavaria definitively in 788, but the Imperial administrative system developed with time into the feudal rule of semi-independent counts In 1004 the emperor Henry II. granted the county of Trent to the bishop of Trent In 1027 Conrad II. enlarged this fief by the counties of Bozen and Vintschgau, bestowing the counties north of this line on the bishop of Brixen

Unable themselves to exercise temporal authority, the bishops delegated their governmental powers to lay lords. The most powerful of these was a family deriving its name from the castle of Tirol, near Meran, who as early as 1150 were counts and bailiwicks of Trent, acquired extensive lands from the bishop of Brixen in 1248, and by 1271 had practically replaced the ecclesiastical power by their own throughout Tirol. This family became extinct with the famous Margaret Maultasch, and Tirol passed by arrangement to Duke Rudolph IV. of Austria (1363). From this date until 1918 Tirol formed part of the Habsburg monarchy. At first Tirol was held as an appanage of a junior branch of the family, but was finally united with the main Austrian possessions in 1665

Tirol's geographical situation, the highway over the Brenner from northern to southern Europe, and the Arlberg route from east to west meeting at Innsbruck, gave it a great strategic importance, since command of the Brenner dominates the gate to Italy. Tirol was therefore frequently the theatre of severe fighting. Its sturdy population, however, guarded its liberties well The spread of Protestantism in Germany occasioned a great peasants' rising in 1525, which forced concessions from the emperor. Although the Counter-Reformation afterwards made of Tirol the most wholly Catholic of all Austrian crownlands, the estates (in which, alone in Austria, the peasants were represented), always preserved an unusual degree of liberty, and Tirol always cherished a strong feeling of unity and local patriotism. The most famous incident in the stormy history of the Tirolese was their insurrection in 1809 against the French and Bavarian rule established by Napoleon after the treaty of Pressburg (1805) Led by Andreas Hofer, the sturdy peasants frequently defeated numerically superior forces; but, after the disastrous peace of Schonbrunn (1809) had given Tirol (except its southern fringe, assigned to Italy) definitely to Bavaria, the revolt was ruthlessly crushed by weight of numbers Hofer was arrested, and finally shot at Mantua by Napoleon's express order (Feb 10, 1810) The Treaty of Paris (1814) reunited Tirol and restored it to Austria

The South Tirol Question.—During the World War the valleys of the South Tirol were the scene of fierce fighting, and the Tirolese poured forth their blood and their money in defence of the Habsburg monarchy Nevertheless they were doomed to suffer even more severely at the hands of the victorious Allies than did their Austrian rulers An irredentist agitation for the annexation of the Italian-speaking Trentino had begun in Italy even before 1848, growing stronger as time went on From the commencement of the war the Italian Government negotiated with both Austria and the Allies for a price for the co-operation of Italy in the struggle The Austrian cabinet agreed to cede the Trentino, but refused to yield to any further Italian demands Italy therefore concluded the Treaty of London (May, 1915) with the allied powers by which she was promised, among other rewards, the Brenner frontier, which she claimed on strategical grounds The Treaty of St Germain (*q v*) handed over to Italy not only the Italian-speaking Trentino but also the Upper Adige, inhabited by a population of purely German origin and speech, and numbering about 215,000 souls. As there were some 13,500 Germans in the Trentino, the total German population included within the new Italy amounted to approximately 229,000 This departure from the principle of national self-determination elicited strong but fruitless protests from the Tirolese communes That a miscarriage of justice had been committed was subsequently acknowledged by one—President Wilson—of the statesmen responsible for it If Italy could put forward a case for her acquirement of the Brenner frontier, based on strategical necessity, she could not honestly advance any racial or political claims to the Upper Adige; nor, indeed, did she advance such claims until the advent of the Fascist Government

At the Peace Conference, Italy was not required to sign any treaty safeguarding the rights of minorities within her frontiers (*See* MINORITIES) Signor Tittoni, however, on December 27, 1919, declared publicly that Italy was under a moral obligation to apply the provisions of the Minorities Treaties towards her own minorities. Similar declarations were made on several occasions by responsible Italian statesmen, and the policy of the Italian Government towards their new subjects was at first not illiberal. Unhappily, both for Italy and the German minority itself, this policy was abandoned by the Fascists in favour of one of Italianization, inaugurated in July 1923—a policy that succeeded only in arousing a spirit of intense resentment and irredentism among the liberty-loving Tirolese

TIRPITZ, ALFRED VON (1849–), German admiral, was born on March 19, 1849, at Kustrin, the son of a high Prussian magistrate, and in 1865 he entered the Prussian navy, the training for which followed the British model In 1869 he became an officer, in 1888 postcaptain, in 1895 rear-admiral; in 1899 vice-admiral; in 1903 admiral, in 1911 Admiral of the Fleet In 1897 he became secretary of state for naval affairs, and then, to his regret, had no further chance of practical service at sea On March 15, 1916, for political reasons, he resigned all his offices

From his 29th year he was employed only in important positions of organisation or leadership His creative talents were first utilised when torpedoes developed into an arm suitable for war, in building torpedo boats and in working out a tactical system for their mass employment His work during this period proved of great value to him later when constructing a fleet of great battleships Here, and in constructing the fleet, he accomplished model work with a minimum of expense After practical service at sea as captain, he became chief of staff of the Supreme Naval Command in 1892, and began the preliminary work for his plan of fleet construction by profound studies in the history and practice of naval warfare The idea of the offensive use of arms was the guiding note of all Tirpitz's work His memoranda, designed to educate the naval officers in modern ideas of their profession, fell into British hands and in this way influenced British tactical ideas also. He combined practical operations with model squadrons of useless ships with the elaboration of his tactical ideas Simultaneously with this went on the transformation of the modern ship of war, with its technical complications, into an apparatus which worked with mechanical perfection He encouraged the education of crews to independent action in all emergencies His tactical memorandum, No 9 (printed in *Nauticus, Jahrbuch fur Deutschlands Seeinteressen*, 1926), afterwards served to convince the reluctant Reichstag of the necessity of forming a German fleet according to definite laws.

General Policy.—As a statesman, Tirpitz aimed at securing the growing maritime interests of the German people He felt the building of a fleet to be a necessity and no luxury, since it made Germany a more acceptable ally and helped to create a sort of balance of power at sea. He considered that it was an economic and a social necessity that the working German people should gain greater independence from all political eventualities. He further saw in Germany the power of the future on which the smaller European powers might lean at sea In view of the formation of great self-sufficient economic units in the world, he probably considered his ideas to be a consistent continuation of Bismarck's train of thought, and perhaps thought of a kind of economic Pan-Europa under a wise German leadership

Tirpitz opposed the suggestion that Germany might annex Holland, one reason being that he was always anxious to spare the small Nordic states. He would also have been prepared to make the Danes concessions in Schleswig in order to win their friendship, and was anxious for Italy to have a considerable fleet. Tirpitz never asked for war and always believed that a war could only interrupt Germany's rise, but he supported a rapprochement with Russia as Bismarck wished it, and a German-Russian-Japanese understanding He disapproved of the German Baghdad policy because it infringed simultaneously on the Russian and British spheres of influence He was against irritating America in any way and disapproved both of the German intervention in Manila and of the British-German blockade of Venezuela. Moreover he saw clearly that in forming Germany into a sea power he would have to reckon with the opposition of Great Britain. He believed firmly, however, that it must be possible, if Germany proceeded with caution, to pass through the danger zone of the time of fleet construction without war, and that, finally, an honest understanding between Germany and Great Britain could only be advanced if Germany was a real power on sea as on land. Summing up British psychology and British love for everything straight and strong, he reckoned that Germanic England, whose statesmanship and power at sea he rated very highly, would in the end prefer a rapprochement with a strong Germany to any other political combination It was only unwillingly and with hesitation that he adopted "the idea of risk" aimed at Great Britain in his naval estimate of 1900.

Even after the outbreak of the World War, Tirpitz did not change his opinion that, taking all in all, the rapprochement between Germany and Britain was advanced rather than hindered by the construction of the fleet, and that only the outbreak of the War, which was most unwelcome to him, had prevented the last maturing of his political aims His naval programme always aimed at leaving Britain a sufficient superiority He considered that the formula of the respective strengths of three to two suggested by Lloyd George, which Churchill later, although with reservations, altered to 16 to 10 or eight squadrons to five, gave Britain sufficient protection against aggressive German intentions

The Naval Programme.—In organising the construction of the German fleet, Tirpitz thought out each step to its last consequences. He refused flatly to construct the greater cruiser fleet which the Emperor was anxious to have when he was appointed secretary of state, in view of the experience of the past with cruiser warfare and the lack of German foreign bases His aim was and remained the formation of a battle fleet. His naval estimates carefully avoided votes for new constructions of ships which depended on the momentary humour of the deputies He aimed at securing legal authority for the number of ships of the fleet to be built, for their regular replacement and maintenance. Inevitably a certain stiffness thus came into the naval programme, which was at times a little inconvenient during the critical years. Tirpitz feared that his successor would abandon important principles of his programme He believed that the diplomats did not grasp the real idea of his programme The squadron of eight ships as a tactical unit was the base of his naval programme. The first law of 1898 approved a double squadron of ships of the line with the necessary cruisers The law of 1900 doubled the battle fleet. Supplementary laws of 1904, 1906 and 1908 reduced the maximum age of ships and thereby altered the plan of new construction. The foreign cruiser fleet and the torpedo-boat forces were increased, and account was taken of the British dreadnought programme The Kiel Canal was widened to take battleships. The supplementary bill which Tirpitz introduced after Agadir in 1912 only increased the number of ships to be constructed by a little, but increased the strength of the active fleet. The supplementary law of 1912 was to be the last bill of the naval programme. The fleet of 1920 was to consist of one flagship of the fleet, five squadrons of battleships of eight ships each, 12 cruisers for home service, eight large cruisers for foreign service and 40 small cruisers, including 10 for foreign service. Three squadrons of ships of the line with the necessary cruisers were to be always ready as a battle fleet. His construction programme was reduced after the negotiations with Haldane in 1912, and only provided for three new ships to be distributed over several years. Taking 61 great battleships and a life of 20 years, three large ships would be launched regularly every year on this plan.

If Britain had really recognised German sea-power, Tirpitz would probably have agreed to some arrangement on the lines of the later Washington agreement of 1922, dealing with the proportionate strength of the two Powers Tirpitz only became deeply interested in the construction of submarines after the Diesel engines were perfected for service in 1908 The ultimate strength of submarines was then fixed at 72. There was never any idea of mercantile submarine warfare. Tirpitz considered the battle fleet to be the best protection for the extensive German coast line, and spent little money on its fortification. But he modernised Heligoland, and expanded it into a fortified harbour. Parallel with the construction of the fleet, the state wharves were systematically expanded and grew to be industrial implements of the first order

Political Relations.—Tirpitz's relations with the Emperor were peculiar. The Emperor could not do without him to organise the expansion of the fleet, although not really liking his rather stiff manner. Tirpitz energetically opposed fantastic plans of naval construction. He often was hampered by William II.'s political ways, but so long as he controlled the construction of the fleet he held firmly to his real aim Tirpitz was a convinced Monarchist and remained so after the War Up to the outbreak of the World War, Tirpitz enjoyed a steadily increasing popularity The circle of his real co-workers and colleagues was, however, always small. The number of his personal friends was even smaller. He was a good judge of men and exploited the special talents of his subordinates ruthlessly He himself always retained his wide general view and never lost himself in details In the corps of naval officers his aims were not always fully understood He probably never revealed his ultimate aims to any of his friends, and, like all great men, was often compelled to stand alone He was careful to keep up relations with deputies and with the press He recognised very early the importance of publicity Before the War Tirpitz exercised but little influence on the Admiralty staff. But he controlled the construction of the ships The orders to the fleet and army at the outbreak of War were not known to him. Before the War he purposely paid little attention to the mobilization plans of the fleet

In politics Tirpitz seldom played an active part. He knew nothing of the British offer of an alliance at the close of the 19th century. Although he offered his advice to the chancellor von Bethmann Hollweg he was not consulted when important political measures were taken; for example, when a cruiser was sent to Agadir in 1911. At the end of 1911, he could have become chancellor of the Reich, but he never desired this office During the critical time of Lord Haldane's visit in 1912, Tirpitz stated that he would have given up his supplementary naval estimate completely for a real neutrality agreement with Britain. He did not entirely approve of the measures taken by the German Government after the murder in Sarajevo (1914) and was for avoiding the threatened war at all costs Tirpitz did not share the opinion that Britain would stand out of the war, and foresaw that the sympathies of America would be on the side of Britain. He was in favour of a short war, and for putting the German fleet to a decisive battle. He believed that the intervention of America would in any case prevent a complete victory, but thought that if Germany exercised all her forces, the German Reich could remain a really great power, and at the worst acknowledge defeat whilst her forces were still unexhausted. He was also against any form of annexation but was only anxious lest the Belgian coast should pass into the possession of Britain In general, he saw the War as the last struggle of freedom against the world capitalism of the Anglo-Saxons.

At the beginning of the War Tirpitz offered to take over the entire control of the navy, including the military control, but this was refused. His advice was hardly listened to by the politicians and hardly ever taken. The naval battle for which he wished was not fought. He early recognised the importance of the new

U-boats for the issue of the War, but was against employing U-boats too early in the commercial War, and named the spring of 1916 as the right moment. He disapproved of the attitude of the German Government during the exchange of Notes with America on the occasion of the sinking of the "Lusitania" and the "Sussex," regarding it as weak. Tirpitz was not implicated in the declaration of the U-boat warfare in 1917, and later stated that had he guessed Russia's coming collapse and known of President Wilson's efforts for peace, he would probably have used his influence against U-boat warfare in 1917.

Post-War Activities.—After leaving his post in 1916, Tirpitz entered politics and helped to found the *Vaterlandspartei;* and after the War had ruined his life's work, he entered the Reichstag in 1921 as German National Deputy. He generally remained in the background in plenary sittings, but he played an influential part behind the scenes. He spoke in favour of the Dawes Plan and against the Pact of Locarno

See article in Nov. 1925 issue of *Sud-deutsche Monatshefte* on attempts at a naval agreement with Great Britain, and Ulrich von Hassel, *Admiral von Tirpitz* For his own statement of the case *see* his *Erinnerungen* (1918) and *Politische Dokumente; der Aufbau der deutschen Weltmacht* (1924). TIRSO DE MOLINA, the pseudonym of Gabriel Tellez (1571–1648), Spanish dramatist Born at Madrid, he professed in the Order of Mercy on Jan. 21, 1601 Sent by his superiors on a mission to the West Indies in 1615, he returned to Europe in 1617, and resided at the Mercenarian monastery in Madrid His first publication, the incomplete *Cigarrales de Toledo* (1621?), is a miscellany, containing short tales, novels, verses and three plays; one of the novels, *Los Tres maridos burlados,* probably derived from Il Cieco da Ferrara's *Mambriano,* and the play entitled *El Vergonzoso en palacio* are admirable examples of witty contrivance The preface to the *Cigarrales de Toledo* (the second part of which was never printed) states that Tirso de Molina had already written 300 plays, and at this period of his career he was second only to his friend Lope de Vega in popularity. He rose to important positions in his order, became superior of the monastery at Trujillo in 1626, was elected later to the posts of reader in theology and *definidor general,* and in May 1632 was appointed chronicler of the Order of Mercy His *Deleitar aprovechando* (1635) is a devout counterpart of the *Cigarrales de Toledo,* much inferior to its predecessor in interest; a sequel was promised to this collection of pious tales, pious lyrics and *autos,* but, as in the case of the *Cigarrales de Toledo,* the continuation never appeared. A first part of Tirso's plays was published in 1627, the third part (before the second) in 1634, the second and fourth in 1635, and the fifth in 1636 A sixth volume of dramatic pieces, consisting of light comedies, was announced; but the project was abandoned As official chronicler of his order, Tirso compiled the elaborate *Historia de la merced,* which occupied him till Dec 24, 1639, and still survives in manuscript, and on Sept. 29, 1645, he became superior of the monastery at Soria He died there on March 12, 1648.

Only a fraction of his plays have been preserved In 1624 he had written 300 plays, and in 1634 he stated that he had composed 400 within the previous 20 years; of this immense production not more than 80 plays are in existence Tirso de Molina is universally known as the author of *El Burlador de Sevilla y convidado de piedra,* the piece in which Don Juan is first presented on the stage; but *El Burlador de Sevilla* represents only one aspect of his genius. No less remarkable than his representation of perverse depravity in *El Burlador de Sevilla* is his dramatic treatment of a philosophical enigma in *El Condenado por desconfiado* Though manifestly attracted by exceptional cases, by every kind of moral aberration, by the infamous and the terrible, his range is virtually unlimited. He reveals himself as a master of historical interpretation in *La Prudencia de la mujer,* and of tragical pathos in *La Venganza de Tamar;* his sympathetic, malicious wit finds dramatic expression in *El Vergonzoso en palacio* and *Don Gil de las calzas verdes,* and the fine divination of feminine character in *Averígüeló Vargas* and *La Villana de Vallecas* is incomparable. Tirso de Molina has neither Lope de Vega's inventive resource, nor his infinite seduction; he has neither Calderon's idealistic visions, nor his golden music; but he exceeds Lope in massive intellectual power and in artistic self-restraint, and he exceeds Calderon in humour, in creative faculty, and in dramatic intuition That his reputation extended beyond the Pyrenees in his own lifetime may be gathered from the fact that J Shirley's *Opportunity* is derived from *El Castigo del penséque;* but he was neglected in Spain itself during the long period of Calderon's supremacy, and his name was almost forgotten till the end of the 18th century, when some of his pieces were timidly recast by Dionisio Solis and later by Juan Carretero. The renaissance of his fame, however, dates from 1839–42, when an incomplete but serviceable edition of his plays was published. He is now accepted as among the greatest dramatists of Spain.

TIRUPATI, a town of British India, in the North Arcot district of Madras, with a station on the Madras and Southern Mahratta railway, 84 m N E of Madras city Pop (1921), 17,434 It is famous for a temple on the neighbouring hill of Tirumala, 2,500 ft above the sea, which is one of the most frequented places of pilgrimage in southern India The town is noted for its brass-work and wood-carving

TIRYNS (Gr. *Tē-runs,* anglicized *ti-rinz*), a prehistoric fortress and afterwards a small Greek city, on an isolated ridge of rock near the east side of the plain of Argos in Peloponnese, about 3 m from the coast, and from the port of Nauplia. There is a railway station close to the site In Greek legend it was founded by Proetus, brother of Acrisius, king of Argos His successor, Perseus, founded Mycenae some 10 m further inland Later, Heracles here served Eurystheus in many "labours," and Tydeus and his son Diomedes held it. After the Dorian conquest (*q v*) Tiryns, like Mycenae, declined as Argos grew, it sent its small contingent to fight at Plataea (*q v*) in 479; but about 460 it was destroyed by the Argives Pausanias (*c* A D 170) was shown here the "palace of Proetus," and the "chambers of his daughters," and wondered at the "Cyclopean" walls, the τίρυνς τειχιόεσσα of Homer *Il* ii 559 The same walls in 1884 attracted the attention of Heinrich Schliemann, the excavator of Troy (1871) and Mycenae (1875), who uncovered, with W Dörpfeld, a prehistoric "palace" remarkable for many points of resemblance to the "House of Odysseus" in the *Odyssey;* but made only a few soundings into the stratified remains under its floors These were carefully examined from 1908 onward by members of the German Archaeological Institute in Athens, and though their conclusions are not yet fully published, the following outline of the archaeology of Tiryns is assured

The natural ridge on which Tiryns stands is about 330 yd from north to south, and 112 at widest from east to west; the greater height of its southern half now is mainly due to superstructures From about 2000 B C a small unfortified settlement can be traced on, and also around this ridge, with three superposed layers of mud-brick houses; on what was probably the summit (under the later *megaron*) was a remarkable round building, nearly 90 ft. across, also of mud brick but roofed with slates and tiles, probably for some public or official use

About 1600 B C. the southern half of the ridge was heavily fortified with rude but massive walls, to protect a new "palace" of which the plan is obscure (for it lies underneath its successor), but the arts and industries are derived, like those of the contemporary "shaft graves" at Mycenae, from the "Middle Minoan" culture of Crete (*q v*) The settlement which it dominated extended some hundreds of feet to south and east of the ridge Communication was by a gateway in the east wall, underneath the later "propylaea." About ½ m away, on the hill called St. Elias,

cist graves and rock-chambers are found, of various dates, and on the same hill is a ruinous "beehive tomb" like those at Mycenae, Heraeum and Midea, and probably contemporary with them, but nothing has survived from its contents

The "early palace" perished by violence and was succeeded, about 1300 B C, by another, which occupied the whole area of the early citadel, and was in turn defended by the massive but rudely-fashioned walls which are now conspicuous. These considerably enlarge the area of the fortress and enclose also the whole of the northern half of the ridge The latter, however, was not occupied by buildings (except a pot kiln and some workshops) but was levelled upwards with debris as a place of refuge for dependants and their cattle The same principal entrance, heavily fortified, in the middle of the east side, served both this "lower citadel" and the "upper" section south of it, which was further protected by an inner gate with bolted doors, as at Mycenae, within which a covered porch (*propylaea*) panelled with wood above a stone plinth, gave access to a level outer court occupying the whole of the south end, and sustained by very thick substructures These contain, on their east and south frontages, the famous "galleries" which served as store rooms in peace, and as casemates in war. As the "later palace" within these fortifications was not itself designed for defence, its construction was slighter, and it has perished above plinth level Its plan, however, which has attracted the attention of commentators on Homer, since Schliemann's time, is completely traceable The outer court gives access, through a second porch, to an inner one, about 53 ft by 70 ft., containing a domestic altar, furnished to east and west by colonnades, and giving access northward through a deep portico with two columns to a vestibule (with three doors outward and one inward) and so to a great hall to which the Homeric name *megaron* is commonly applied This hall, about 40 ft by 30 ft., has a central hearth, between four column bases, which supported a roof with some kind of louvre or clerestory to let out the smoke. On the cement floor, which is ornamented with painted panels of octopus and dolphins, a space is marked out between the hearth and the east wall, as the place of honour, but there is neither dais nor any other doorway but that of the vestibule. From the latter a small door leads west to a bathroom, of which the floor is a single limestone slab draining to the main sewer, as at Cnossus (*q.v*); in this room were found the remains of a clay bath-tub

This "later palace" also perished by violence, and parts of its mud-brick walls were so calcined that at first sceptical scholars acclaimed them as Byzantine, and there was, in fact, a small Byzantine church (now removed), with a graveyard near the south end of the site As it evidently lay long desolate, little remains of its decorative splendour except fragments of fresco, and of an alabaster frieze inlaid with blue enamel like the θριγκὸς κυάνοιο of *Od.* vii. 87. The pottery is of degenerate Late Mycenaean style

The frescoes of the "earlier palace," with rich spiral and floral designs, resemble those of contemporary Cnossus (*L M*, i. ii); those of the "later" included a majestic procession of women bearing offerings, an elaborate hunting scene, in which a boar is attacked by hounds and men, and other animals are represented, an assault on a palace; a chariot procession; and bull-baiting gymnastic of the Cnossian kind. A small painted plaque shows the worship of an armed goddess; and a fragment with ass-headed personages may be a masquerade

To the centuries after the destruction of the palace belong a series of graves with pottery of "geometrical" style, safety pins, and other objects of the Early Iron age In the 7th century a temple was dedicated to Hera on the site of the Mycenaean *megaron*, and furnished with rude terracotta offerings.

TISA (Ger. *Theiss*), tributary of the Danube, rises in the north-eastern Carpathian mountains in Ruthenia at a height of about 6,300 ft, and is formed by two streams, the Black Tisa (Cerna Tisa) and the White Tisa (Bilá Tisa) which unite above Rachovo where the mountain valley begins to widen A few miles below Rachovo the river takes a generally westerly direction and makes a great curve around the Nyirség plateau entering Hungary near the top of the curve and then continuing south-west to Szolnok From here its course across the Hungarian plain is parallel to the Danube, which it enters near the small plateau of Titel, 20 m. east of Novisad The winding course is about 870 m. long and the basin, covering an area of 56,600 sq m., is shared by Czechoslovakia, Hungary, Rumania and Yugoslavia Two of its tributaries, the Szamos and Maros, coming from the impermeable rocks of Transylvania, bring a great volume of water, but these and the main stream quickly lose their velocity on reaching the plain where the fall is less than 3 cm per km. Two periods of high water occur on the middle and lower Tisa, one in spring due to snow melting, the other in June following the summer rain; to this the Körös is a big contributor The spring flood coincides with that of the Danube which, having a quicker flow, dams back the Tisa and causes extensive flooding sometimes felt as far as Szolnok Huge canalisation and diking works have been undertaken to protect the surrounding lowland. The Tisa is navigable for steamers as far as Szolnok, 197 m., or as far as Tiszafured, 255 m, depending upon the stage of the water, and for rafts and floating timber almost anywhere. It is joined to the Danube by the Francis Joseph canal and its tributary, the Béga, and is canalised to Timisoara

TISCHENDORF, LOBEGOTT FRIEDRICH KONSTANTIN VON (1815–1874), German biblical critic, the son of a physician, was born on Jan 18, 1815, at Legenfeld, near Plauen, in the Saxon Vogtland He was educated at the gymnasium of Plauen and the university of Leipzig, where he qualified as a lecturer in 1840 with a dissertation on the recensions of the New Testament text. These studies convinced him of the absolute necessity of new and exacter collations of mss. From October 1840 till January 1843 he was in Paris, studying in the great library, eking out his scanty means by working for other scholars and for the publisher Didot The great triumph of these laborious months was the decipherment of the palimpsest *Codex Ephraemi Syri Rescriptus*, abandoned as illegible by earlier collators The New Testament part was printed before he left Paris and the Old Testament in 1845. From Paris he had paid short visits to Holland (1841) and England (1842). In 1843 he visited Italy, and after a stay of thirteen months went on to Egypt, Sinai, Palestine and the Levant, returning by Vienna and Munich. (*See* his *Reise in den Orient* [Leipzig, 1845–46]) From Sinai he brought a great treasure, forty-three leaves of what is now known as the *Codex Sinaiticus* He kept the place of discovery a secret, and the fragments were published in 1846 as the *Codex Friderico-Augustanus*, a name given in honour of the king of Saxony. He now became professor extraordinarius in Leipzig, and married (1845). In the same year he began to publish an account of his travels in the East (2 vols, 1845–1846). In 1850 appeared his edition of the *Codex Amiatinus* and of the Septuagint version of the Old Testament; in 1852, amongst other works, his edition of the *Codex Claromontanus*. In 1853 and 1859 he made a second and a third voyage to the East. In the last of these, in which he had the active aid of the Russian government, he at length got access to the remainder of the precious Sinaitic codex, and persuaded the monks to present it to the tsar, at whose cost it was published in 1862 (in four folio volumes). In 1859, he had been made professor of theology and biblical palaeography. The mss. brought to Europe on the first two journeys are catalogued in the

Anecdota sacra et profana (Leipzig, 1855, enlarged 1861). *See* also the *Monumenta sacra inedita* (Leipzig, 1846), and *Nova collectio* of the same (1855–1869). The 3rd volume of the *Nova collectio* gives the results of his last Eastern journey. Side by side with his industry in collecting and collating mss, Tischendorf pursued a constant course of editorial labours, mainly on the New Testament, until he was broken down by overwork in 1873. He died on Dec. 7, 1874, at Leipzig.

Four main recensions of Tischendorf's text of the New Testament may be distinguished, dating respectively from his editions of 1841, 1849, 1859 (*ed. vii.*), 1869–72 (*ed. viii.*) The edition of 1849 may be regarded as historically the most important from the mass of new critical material it used; that of 1859 is distinguished from Tischendorf's other editions by coming nearer to the received text; in the 8th edition the testimony of the Sinaitic ms received great (probably too great) weight

His edition of the Roman text, of the *Septuagint*, with the variants of the Alexandrian ms, the Codex Ephraemi and the Friderico-Augustanus, was of service when it appeared in 1850, but, being stereotyped, was not greatly improved in subsequent issues. Besides this may be mentioned editions of the New Testament Apocrypha [*De Evangeliorum apocryphorum origine et usu* (1851), *Acta Apostolorum apocrypha* (1851); *Evangelia apocrypha* (1853; 2nd ed, 1876); *Apocalypses apocryphae* (1866)] and various minor writings, in part of an apologetic character, such as *Wann wurden unsere Evangelien verfasst?* (1865, 4th ed, 1866), *Haben wir den echten Schrifttext der Evangelisten und apostel?* (1873), and *Synopsis evangelica* (7th ed, 1898).

See in addition to the handbooks on New Testament criticism, Carl Bertheau's article on Tischendorf in Herzog-Hauck, *Realencyklopadie* (3rd ed, 1907).

TISI, BENVENUTO (1481–1559), commonly called Il Garofalo, one of the most distinguished painters of the Ferrarese school, was born at Ferrara His father, Pietro Tisi, head of the shoemakers' guild in that city, originally came from Garofalo, a village in the Polesine According to Vasari, the boy first studied with Domenico Panetti, and then went to an uncle at Cremona, where he frequented the workshops of Boccaccio Boccaccino In 1499 he proceeded to Rome and remained 15 months with Giov. Baldini, a Florentine painter. Family affairs caused his return to Ferrara in 1501 Soon afterwards he may have worked under Lorenzo Costa in Mantua. In 1504 he was again at Ferrara, where he became friendly with the two brothers Dossi. Towards the close of 1509 he returned to Rome and made the acquaintance of Raphael and saw Michelangelo's frescoes on the vault of the Sistine chapel just completed After 1512 we find him settled at Ferrara, never quitting the city for any length of time until his death in 1559 His earlier works recall the style of Panetti and Boccaccino In his middle period he was influenced by his association with Dossi Then Raphael's and Michelangelo's influence made itself felt. He was a prolific artist and almost every church of Ferrara was supplied with a picture from his brush Garofalo's earliest dated picture, "The Minerva and Neptune" of 1512, in the Dresden gallery, displays the influence of Lorenzo Costa. His paintings in the Borghese and Doria collections are probably earlier, being in the manner of Dossi and Boccaccino. Other important works are "The Immaculate Conception" (1514) and "The Madonna del Pilastro" in the pinacoteca at Perugia and "The Mater Dolorosa" at Dresden He did not always confine himself to sacred subjects, and one of his finest works dealing with mythology is "The Sacrifice to Ceres" in the National Gallery (Mond collection). He was also employed in decorating palaces of Ferrarese nobles His paintings in monochrome in the Seminario at Ferrara are fine and well preserved, and those in the ceiling of one of the rooms recall Mantegna's ceiling in the Camera du Sposi at Mantua He continued constantly at work until, in 1550, blindness overtook him

See G. Morelli, *Italian Painters, The Borghese and Doria Galleries* (1892–93); J. E. G. Gardner, *The Painters of the School of Ferrara* (1911).

TISSAPHERNES (Pers. *Cithrafarna*), Persian soldier and statesman, son of Hydarnes. In 413 he was satrap of Lydia and Caria, and commander in chief of the Persian army in Asia Minor (Thuc. viii. 5). When Darius II. ordered the collection of the outstanding tribute of the Greek cities, he entered into an alliance with Sparta against Athens, which in 412 led to the conquest of the greater part of Ionia. But Tissaphernes was unwilling to take action and tried to achieve his aim by astute and often perfidious negotiations; Alcibiades persuaded him that Persia's best policy was to keep the balance between Athens and Sparta, and rivalry with his neighbour Pharnabazus of Hellespontic Phrygia still further lessened his energy When, therefore, in 408 the king decided to support Sparta strenuously, Tissaphernes was removed from the generalship and limited to the satrapy of Caria, whereas Lydia and the conduct of the war were entrusted to Cyrus the Younger On the downfall of Athens, Cyrus and Tissaphernes both claimed jurisdiction over the Ionian cities, most of which acknowledged Cyrus as their ruler; but Tissaphernes took possession of Miletus, where he was attacked by Cyrus, who gathered an army under this pretence with the purpose of using it against his brother Artaxerxes II. The king was warned by Tissaphernes, who took part in the battle of Cunaxa, and afterwards tried to destroy the Greek mercenaries of Cyrus by treachery He was then sent back to Asia Minor to his old position as general in chief and satrap of Lydia and Caria He now attacked the Greek cities, to punish them for their allegiance to Cyrus This led to the war with Sparta in 399 Tissaphernes, who once again had recourse to subtle diplomacy, was beaten by Agesilaus on the Pactolus near Sardis (395); and at last the king yielded to the representations of Pharnabazus, strongly supported by the chiliarch (vizier) Tithraustes and by the queen-mother Parysatis, who hated Tissaphernes as the principal cause of the death of her favourite son Cyrus Tithraustes was sent to execute Tissaphernes, who was lured to Colossae and slain in 395 (Ed M)

TISSERAND, FRANÇOIS FÉLIX (1845–1896), French astronomer, was born at Nuits-Saint-Georges, Côte d'Or, on Jan 13, 1845 He entered the École Normale Supérieure in 1863, and in 1866 became *astronome adjoint* at the Paris observatory In 1868 he took his doctor's degree with a brilliant thesis on Delaunay's method He went to Malacca to observe the solar eclipse of Aug 1868 In 1873 he became director of the Toulouse observatory, and while there published *Recueil d'exercices sur le calcul infinitésimal.* He went with the French expedition of 1874 to Japan, and of 1882 to Martinique, to observe the transits of Venus In 1878 he became a member of the Académie des Sciences, and of the Bureau des Longitudes, and in 1883 he obtained the chair of celestial mechanics at the Sorbonne In his principal work, *Traité de mécanique céleste* (4 vols, 1888–96), he coordinated the researches of Laplace and of subsequent workers in the same field, and gave a *résumé* of the state of knowledge in that department of astronomy at the end, as Laplace's *Mécanique céleste* did for the beginning of the 19th century In 1892 he became director of the Paris observatory. He died suddenly on Oct 20, 1896

TISSOT, JAMES JOSEPH JACQUES (1836–1902), French painter, was born at Nantes on Oct 15, 1836 He studied at the École des Beaux Arts in Paris under Ingres, Flandrin and Lamothe In 1861 he showed "The Meeting of Faust and Marguerite," which was purchased by the state for the Luxembourg Gallery. He fought in the Franco-German War, and, falling under suspicion as a Communard, left Paris for London Here he studied etching with Sir Seymour Haden, drew caricatures for *Vanity Fair,* and painted portraits as well as *genre* subjects It was many years before he turned to the chief work of his career—the production of a series of 700 water-colour drawings to illustrate the life of Christ and the Old Testament He disappeared from Paris, whither he had returned after a stay of some years in England, and went to Palestine In 1895 the series of 350 drawings of incidents in the life of Christ was exhibited in Paris, and in 1896 in London They were then published by the firm of Lemercier in Paris. He died at Buillon (Doubs) on Aug 8, 1902

TISSUE CULTURE. The body is composed of countless myriads of cells assembled in tissues and organs. The cells belong to several types: wandering cells such as blood leucocytes and tissue macrophages which roam through the entire organism; epithelial cells, the noblest elements of the body, which form the glands, brain, skin, etc.; connective tissue cells present everywhere under various appearances, etc They are the units of a strictly organized community. Their existence is bound to that of the whole. If the whole is taken apart, its component tissues and

organs die after a short time. The cultivation of tissues consists precisely in maintaining in a condition of active life cells that have been removed from the body. The aim of this method is to study the innate properties of each cell type, and the mechanism of their organization into tissues and organs. Its ultimate purpose is the discovery of the laws which express the relations between the tissues and the body fluids, and the building up of cell sociology.

History.—The method of tissue culture may be considered the indirect outcome of studies made independently by several biologists on the survival of cells outside of the organism However, the first chapter of its history was written in 1907 by R G. Harrison in the beautiful experiments where nerve fibres were caused to grow *in vitro* from fragments of the central nervous system of frog embryos. In 1910, these experiments were extended by other workers to adult and embryo tissues of birds and mammals, which were observed to survive in a drop of plasma But after a few days, degeneration began and death occurred. In these experiments, as well as in those of Harrison, the tissues were not cultivated in the proper sense of the word. They were only in a condition of survival. A second chapter was begun in 1911 when A. Carrel developed a procedure by which the death of the surviving tissues could be indefinitely postponed and found, in 1912, that embryo proteins possess the power of promoting the unlimited proliferation of tissue cells. Then, it became possible really to cultivate cells, that is, to cause them to manufacture new protoplasm from the substances contained in their medium. A long interruption occurred in the progress of these investigations due to the World War. But, in 1921, the development of procedures permitting the main cell types to be obtained in pure cultures opened a third and important period in the history of the method. Blood and tissue macrophages, iris epithelium, cartilage cells, thyroid cells, Malpighian epithelium, lens cells, and several types of malignant cells were isolated from other tissue elements and maintained in a pure state. At the same time, it became possible to measure accurately the rate of growth of the strains of tissue cells. New procedures were perfected by which living tissues could be maintained indefinitely in flasks where they were washed, fed, and measured without being disturbed and without danger of infection from bacteria. These great practical improvements rendered the method of tissue culture very much easier, and widely extended its application to physiological and pathological problems. Although it has not as yet reached its complete development, it may be considered the most powerful instrument now possessed for the investigation of cell physiology.

Technique.—The handling of the delicate and minute structures which compose the tissues demands elaborate techniques and a long apprenticeship for their mastery But the principles of these techniques are very simple The cells are cultivated in flat, round flasks made of pyrex glass and varying in size from 3 to 8cm. in diameter (*see* fig.). The flasks possess a wide, oblique neck 3cm. in length Dust and bacteria from the air do not fall into the flask when it is opened, but remain on the wall of the neck where they are destroyed by flaming. By means of a spatula, the tissue cells are conveniently handled inside the flasks After being flamed, the neck is hermetically sealed with a rubber cap. It is thus possible entirely to protect the tissues against bacteria which are their deadly enemies, and also maintain in the air of the container the proper amount of humidity and of carbon dioxide. Through the bottom of the flask, the tissues may be examined with a microscope at a magnification of about 120 diameters. When the cells must be studied in greater detail, they are removed from the flask with a spatula, placed on a thin cover-glass, and examined while still living, at a magnification of 1,500 diameters.

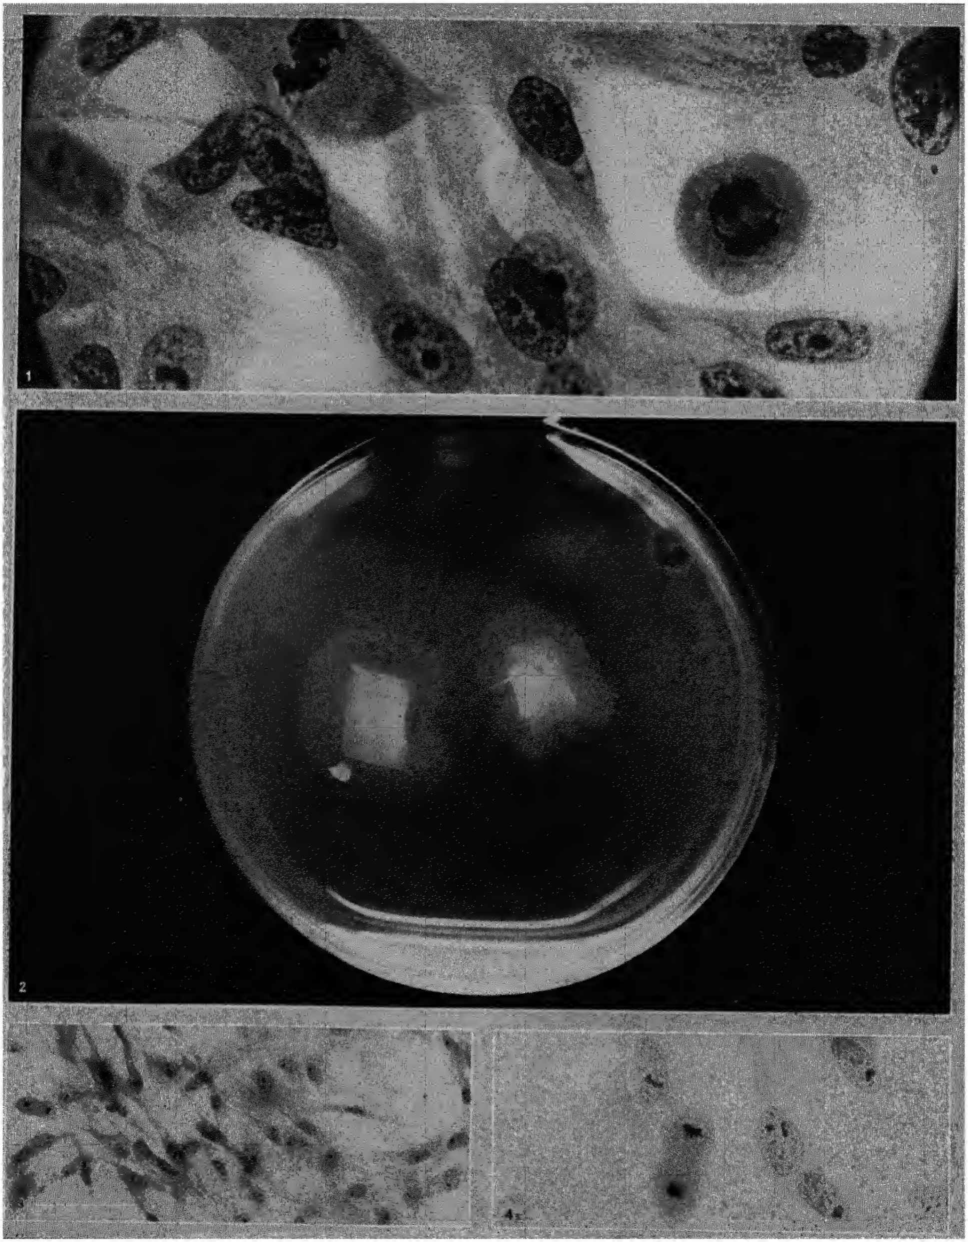
FLAT ROUND FLASK 3.5 CM. IN DIAMETER. FOR CULTIVATION OF TISSUES

1. Solid medium; 2. nutrient fluid medium

On the bottom of the flask is spread the medium which must supply the tissues with a scaffold for their growth and with the substances necessary for the synthesis of new protoplasm. This medium is composed of two parts, one solid and the other fluid (fig 1). The solid part is made of coagulated blood plasma, that is, of a clot of blood from which the red and white corpuscles have been removed. Such a plasma is obtained by freeing blood of its corpuscles by centrifugation. It then becomes a clear, citrin fluid which is introduced into the flask with a pipette. The tissue cells are next deposited by a spatula in this medium which coagulates after a few minutes. Thus they become embedded in a transparent jelly, which they use as a scaffold, but not as a nutrient medium. The fluid medium is placed on the surface of the coagulum. Its rôle is to remove the waste products of the culture, and to supply the tissues with the necessary nutrient substances. Every two or three days, the fluid is removed and replaced by a large amount of a saline solution composed of sodium, potassium and calcium chlorides, sodium phosphate and bicarbonate, and glucose, which is called Tyrode solution. After the tissues have been thoroughly washed, the fluid is removed and replaced by a small amount of nutrient medium. This medium ordinarily consists of embryo proteins, or proteoses and peptones, or blood serum, according to the nature of the tissues. The tissues and fluids are handled with sterile instruments in rooms which are kept strictly clean It is most important that no bacteria be allowed to penetrate into the flasks. If infection of the medium takes place, death of the tissues soon occurs. This accident is almost completely prevented by the recently developed techniques After the preparation of the culture is completed, the flasks are placed in an incubator and maintained at body temperature

Several cell types have so far been obtained in pure state: connective tissue cells or fibroblasts, epithelial cells, blood and tissue macrophages, and the malignant elements of a few tumors. Strains of fibroblasts are cultivated easily from almost every embryo, or adult tissue of human beings, dogs, rats, mice, fowls, etc. They remain packed together while macrophages wander through the medium. In addition, they multiply more rapidly than epithelial cells. Therefore, it is easy to obtain colonies composed exclusively of them Fibroblasts are either polygonal or spindle-shaped with long, sharp processes, and with an oval nucleus which generally contains two smaller nucleoli. They aggregate in a dense tissue which doubles in volume every 48 hours when kept at body temperature in a medium composed chiefly of embryo proteins. They grow indefinitely. A strain of chicken fibroblasts isolated 16 years ago is multiplying to-day at the same rate as at the beginning of its life *in vitro*. When the flasks are taken from the incubator and kept at room temperature, the cells stop multiplying and remain in this condition for three or four weeks without dying. Therefore, living culture cells can be sent for long distances without inconvenience Strains of tissue cells have been exchanged between laboratories located in New York and Berlin and after this long journey have promptly regained their usual rate of growth. Epithelial cells are more difficult to obtain in pure culture. Nevertheless, since Fischer isolated a strain of epithelium from the few cells of the iris which adhere to the lens of the chick embryo, pure cultures of thyroid gland, Malpighian epithelium, lens epithelium and several types of carcinomatous cells have been obtained by Ebeling, Kirby, Fischer and Carrel. Their rate of growth is less than that of the connective tissue cells, but they can be maintained in a condition of active life for several years. They keep their normal characteristics indefinitely. They grow in a thin layer at the surface of the solid medium, and rarely form a dense tissue. They readily digest the coagulum. Leucocytes from the blood and wandering cells from the tissues have also been obtained in pure cultures. They do not aggregate as a tissue, but remain isolated from one another and scatter through the medium. When they accumulate in a large number or are packed together, they generally die or become transformed into fibroblasts. Their growth is slow and they are less resistant than epithelial or connective tissue cells. However, they can live in flasks for several months The malignant elements of sarcomata and carcinomata have also been isolated and maintained alive indefinitely outside of the body.

The rate of growth of the colonies of epithelial cells and of



FIBROBLAST STRAINS

1. A 17 month old strain of Sarcomatous Fibroblast (a cell forming connective tissue) of a rat. 2. Two colonies of 17 month old strain of malignant fibroblasts from a rat sarcoma (tumour of embryonic connective tissue) growing in a flask 3.5" in diameter. 3. Pure strain of normal rat fibroblasts. 4. A 16 year old strain of normal chicken fibroblasts

fibroblasts can easily be ascertained. The measurements are made by placing the flasks on a projectoscope and drawing the outline of the colony immediately after the preparation of the culture and subsequently every two days. The area of the colony at the different stages of its development is measured with a planimeter, and the ratio of the area of new growth to that of the original fragment is calculated. The relative increase of the colony in 48 hours expresses the rate of growth. The curve representing the continuous growth of a colony of epithelial cells or of fibroblasts in a flask containing a nutrient medium is a parabola. If the medium is non-nutrient, the curve is S-shaped. Modifications in the form of this curve indicate whether the medium contains substances that activate or depress the rate of cell multiplication. This method cannot be used for measuring the activity of wandering cells, because they never grow as a tissue, but remain at certain distances from one another and scatter on several planes. Their rate of multiplication can be approximately reckoned by the time taken by the cells to invade the entire area of the flask.

The growth energy of a colony at a given instant is a function of several independent variables: its growth energy at the preceding instant, and the concentration in the pericellular fluid of the substances that increase or decrease cell activity. It could be ascertained by the activity displayed during an instant by the cells in a medium containing neither activating nor retarding substances, if such a measurement were possible. But the residual growth energy, which was found to vary at the same time as the inherent energy, may be used as a measurement of the latter. The residual energy is expressed by the duration of life and the proliferative activity of the cells in Tyrode solution.

The morphology of the tissue cells growing *in vitro* is studied while they are living Fragments of the coagulum containing cells are taken from the flasks and put on thin glass slides. They may also be readily cultivated in glass chambers especially constructed for cytological studies. The living unstained cells are photographed or cinematographed When stained with neutral red, trypan blue, and Janus green, the cytoplasmic structures may be observed while in full activity. Cinematographic records can be taken at such a magnification that the details of the mitochondria, segregation apparatus, and surface membrane of the cells are clearly shown

Mode and Rate of Growth of Tissues.—This method has already supplied some important information regarding the physiological properties of tissue cells, the rôle of blood serum toward the tissues, and the nature of the chemical substances that determine the unlimited multiplication of fixed cells. The rate of growth of connective tissue and of epithelial cells in a nutrient medium of unvarying composition remains uniform indefinitely. Such a law appears to be the expression of one of the more fundamental properties of tissue cells. Since their rate of growth remains unchanged as long as the medium does not vary, the cell colonies may be considered to be immortal. A strain is able to transform an unlimited amount of chemical energy. The energy spent by the cells must arise entirely from the substances contained in the culture medium, and will never be exhausted as long as the same medium is supplied to them. It appears that the potentialities of tissues are much greater than those they display within the normal organism, and that the manifestation of their activity is determined by the physico-chemical conditions of the pericellular fluid. The dependence of cells on the composition of the medium was further emphasized by a study of the rate of growth of colonies of fibroblasts or epithelial cells in media of varying composition. It was found that the activity of the colonies is a function of the concentration of nutrient substances within the medium, when waste products and other inhibiting substances are constantly removed. If cell colonies in different conditions of activity are placed in similar media, their rates of multiplication soon become identical. Fragments of connective tissue of chick embryos and adult chickens cultivated in a nutrient medium grew at first at varying rates, but after a few weeks no difference was observed in the activity of both colonies.

The residual energy of embryo tissues, which is always very large, varies in inverse ratio with the age of the animal from which the tissues have been extirpated. The duration of their survival *in vitro* may extend over a period of three months. On the other hand, the residual energy of the tissues of an adult animal is very small. The connective tissue cells of an old animal are in a dormant condition. If cultivated in a nutrient medium, a long time elapses before they begin to proliferate. Should their resting state be attributed to a factor preventing them from spending their energy, or to a complete lack of energy? An investigation of the behaviour of these tissues in a medium completely lacking in nutrient substances showed that they possess very little residual energy. This means that they have no reserves in store However, they have not lost the power of accumulating the substances which supply them with energy. When they are placed in a nutrient medium, they begin to multiply and to store up reserves. Adult fibroblasts may be compared to a motor which possesses no energy of its own, but runs as soon as it is supplied with fuel.

The persistence of the essential characteristics of cells cultivated *in vitro* has opened a new field to histology. When the rate of growth and the constitution of the medium of a pure strain have been ascertained, the relations existing between the structure of the cells and their physiological state become apparent immediately. Blood monocytes, tissue macrophages and fibroblasts have been studied according to these principles. The appearance of the cells varies greatly with their nutritional condition. The anatomy of a cell type can be modified at will by simple changes in the nature and the concentration of the substances contained in its medium

A profound transformation of classical cytology began when it became possible to identify cells not only by their morphology, but also by their physiological characteristics Through the new techniques, a cell type is defined by the appearance of its colonies, its mode of locomotion as recorded by cinematography, its effect on the medium, its rate of growth, the nature of the substances which inhibit its multiplication, the nature and concentration of the substances required for proliferation, etc. The advantages of this conception of cytology are obvious. If all the manifested and hidden potentialities of every cell type were known, the behaviour of a tissue under given conditions could be predicted. The events in which the tissues take part are determined by the response made to the physico-chemical conditions of the medium by each cell according to its innate qualities. On the mode of response of a cell type to other cells and to the humours depend the characteristics of the community.

Physiological Factors of Growth.—The effect of blood plasma on tissue cells remained unknown until it was tested on pure cultures of fibroblasts and epithelium These experiments showed that, first, blood serum is not a nutrient medium for epithelial cells and fibroblasts; it inhibits their proliferation when added to a nutrient medium. Secondly, blood serum is an excellent nutrient medium for monocytes, tissue macrophages, and sarcomatous macrophages Thirdly, the proteins and amino acids of the blood do not promote the proliferation of connective tissue and epithelial cells. Serum proteins or lipoids possess the property of restraining cell proliferation But blood serum taken from an animal a few weeks old neither stimulates nor inhibits the growth of colonies of fibroblasts. When the age of the animal increases, its serum becomes more and more growth-inhibiting. The progressive increase in the growth-inhibiting properties of blood serum takes place rapidly at the beginning of life and very slowly in old age. The curve expressing this phenomenon resembles that of the decrease in function of the age of the patient in the rate of healing of a wound, as expressed in du Noüy's equation. The age of an animal can be ascertained approximately by the growth index of its serum The inhibiting power of serum is due chiefly to lipoids. After extraction of the lipoids, the remaining proteins are far less inhibiting than the whole serum. On the contrary, the isolated lipoids are toxic. In old age, the inhibiting effect of serum is augmented because both proteins and lipoids are more concentrated.

The nature of the substances responsible for cell multiplication remained unknown until fibroblasts and epithelium were found to multiply with great velocity in the presence of embryo juice.

This juice is a complete food. For 16 years, a strain of fibroblasts has been fed on it, and has built up many thousands of colonies from the substances that it contains. The substance responsible for the unlimited growth of the cells is a protein, which is mixed with a lipoid having some inhibiting power. The primary split products of certain proteins produce as extensive a multiplication of fibroblasts as embryo juice does. The incomplete digests of ox fibrin, casein, egg albumin, liver, testi, thyroid, thymus, pituitary gland, etc, increase the rate of growth of fibroblasts, epithelial cells and macrophages The split products of crystalline egg albumin, on the contrary, possess little growth-promoting power. When the digestion is carried further and the digests are composed chiefly of amino acids, their effect on the growth of tissue cells disappears almost completely It is probable that the proteins of embryo juice are not absorbed as such by the cells after they have been hydrolyzed. The power of tissue juice to cause growth may possibly be attributed to the ease with which its proteins can be transformed into polypeptides by the tissue ferments. Monocytes and macrophages do not require embryo juice or protein split products in their medium in order to proliferate and manifest other forms of activity. They are voracious cells and feed upon red blood corpuscles, protein precipitates and muscle fragments, and also on plasma, embryo juice and protein split products at a low concentration.

Through the method of tissue culture, the fundamental characteristics of the main cell types and the mechanisms that make them an organized whole are being progressively elucidated Although the techniques will be still further improved, they have reached such a degree of development as to permit the construction of a new science of cytology based not only on the morphology, but chiefly on the physiological properties of the cells.

TISTA, a river of northern India, which rises on the edge of the Tibetan plateau, has a tumultuous course southward through the mountain gorges of Sikkim and Darjeeling and flows through North Bengal and Cooch Behar for another 170 miles till it joins the Brahmaputra in the district of Rangpur In the 18th century its course was due south to join the Ganges; but in 1787 great floods diverted the stream towards the south-east, and it made its way by a new channel into the Brahmaputra

TISZA, ISTVÁN (Stephen), COUNT (1861–1918), Hungarian statesman, was born on April 22, 1861, youngest son of Kálmán Tisza (*q v*) Educated at Berlin, Heidelberg and Budapest, he entered the ministry of the interior, where he specialized in agrarian matters His *Magyar agrárpolitik* (Budapest, 1897), authoritative on its subject, was translated into German the same year. In 1886 Tisza began his long parliamentary career, and on June 17, 1903, he was entrusted with the formation of a ministry of pacification, but was unable to secure a majority On Oct 27, however, with the assistance of the Free Principles Party, he succeeded in composing a cabinet, in which he was minister of the interior as well as premier On Nov. 16–18, to meet the obstruction of the opposition, he introduced new and stringent rules of procedure which he declared adopted, thereupon suspending the session The Andrássy group, however, left him soon after, and after a stubborn battle with anarchical conditions in which legislation was impossible Tisza appealed to the country and was heavily defeated After Count Khuen-Hédervary became prime minister (Jan. 1910) Tisza reorganized the old Liberal party under the name of the National Party of Work with a programme of a return to the strict principles of the compromise of 1867. In the elections of June 1910 this party secured an overwhelming majority, due largely to Tisza's own personal suggestion and unceasing activity. In view of the obstruction of the extreme Left against the army legislation, Tisza, considering that the threat of complications in the Balkans made it essential not to weaken the Austro-Hungarian army, had himself elected president of the Lower House in 1912, introduced new standing orders, and forced the Army bill through, ejecting the opposition from the House. A member fired three times at Tisza, who remained calm in his chair This scene made him very popular. He had to fight some duels with his adversaries, including one with Count Michael Karolyi, which left the two adversaries bitter enemies.

On June 15, 1913, Tisza was for the second time nominated prime minister. In his first memorandum on foreign policy, written after the second Balkan War, he deplores the growth of Serbia and the collapse of Bulgaria, Turkey and later Greece. Rumania, where public opinion was growing hostile to the dual monarchy, should be assured its territorial integrity, but if it abandoned its alliance, Bulgaria should be brought to bear against it. War should be avoided In home politics, Tisza was willing to favour such of the non-Hungarian nationalities as would support the State. He attempted to reach an understanding with the leaders of the Transylvanian Rumanians, but without success.

After the murder of the heir to the throne at Sarajevo, Tisza, in a letter to Francis Joseph (July 1) opposed Berchtold's suggestion for a sudden attack on Serbia. A week later he again urged his view that diplomatic steps were necessary and a severe ultimatum should be sent, but its conditions should not be impossible of acceptance. To avoid the intervention of the Entente, Tisza carried a motion in the council of ministers (July 19) that the integrity of Serbia's territory should be respected even if war was declared Though the war against Serbia was declared, he exerted himself for peace by accepting Sir Edward Grey's last proposal (July 31). Afterwards he was anxious to miss no opportunity of concluding peace. He was opposed to all German aspirations of territorial aggrandizement and to the introduction of unlimited submarine warfare. He was a true partisan of German alliance, but he admitted no interference with Hungary's sovereign rights and was strongly opposed to the German idea of an economic "Mittel Europa"

Tisza had many controversies with the Austrian Supreme Command and general staff He was convinced that the fate of Hungary was bound up with that of the dual monarchy, but equally intent on preserving Hungary's predominance within the monarchy. It was for this reason that he opposed the plans of Conrad von Hotzendorf (*q.v.*) to annex further territory, and advocated moderate peace terms in Serbia and Belgium He refused, however, to make any territorial concessions to Rumania, such as might have kept her from joining the war against the Central Powers His influence was immense so long as Francis Joseph lived. It was he who forced Berchtold to leave the foreign ministry although he refused himself to become foreign minister.

King Charles, however, was under the influence of Tisza's Austrian and Hungarian enemies. Their rancour was fostered by the participation of Tisza, a Calvinist, with the primate of Hungary in the act of coronation. The pretext for Tisza's dismissal in June 1917 was his refusal to grant the suffrage to soldiers at the front and his opposition to the demands of the Socialists.

The new cabinet had but a minority in parliament. Tisza, now chief of the opposition and in the majority, framed a resolution in which he affirmed the necessity of the German Alliance and pointed out the ambiguous behaviour of the Czechs in the Reichsrath. Finding his position difficult, he went to the front. In the Bukovina and in Italy he commanded a regiment with distinction. During this time his only political action was his mission to Croatia and Bosnia (Sept. 1918). Returning to Budapest, he declared (Oct 17) "We have lost the war," and thus gave the signal for the collapse. He wanted a peace with honour, not a treacherous one. His last two weeks he spent in attempting to unite different parties; he was even ready to accept Karolyi's leadership in order to save the country and to procure a good peace Too proud and too conscientious to allow the publication of his pacific endeavours, he was set as a mark for the defeatist soldiers and the mob. Though warned of his grave danger, he remained in Budapest, working until his last moment to unite the historical parties. He was killed by soldiers on Oct. 31, 1918, the first day of Count Karolyi's revolution. His last words were, "It had to be."

See István Tisza, *Ossres Munke*, 2 vol., 1925 (Personal Recollections,

letters June to end of Dec. 1914, pub. by the Hungarian academy). The first volume of the letters was translated into German by O. von Wertheimer, *Graf Stefen Tisza; Briefe* (1928).

TISZA, KÁLMÁN [Koloman] (1830–1902), Hungarian statesman, was born at Geszt on Dec 10, 1830, the son of Lajos Tisza and the countess Julia Teleki, and educated at his father's castle. In 1848 he obtained a post in the ministry of instruction of the revolutionary Government. After the war he travelled abroad, afterwards (1855) becoming assistant curator of the Calvinist church at Nagyszalonta He publicly and vehemently opposed the Austrian "Patent" of Sept 1, 1859 and the "October Diploma" of 1860 In Aug. 1860 Tisza married the countess Helen Degenfeld-Schomburg, a union which brought him into close connection with the Karolyis, the Podmaniczkys and the Odescalchis. He was unanimously elected to represent Debreczen at the 1861 diet, and vice-president of the house at its second session, and became leader of the more radical party on the death of Count László Teleki

From 1867 onwards his influence increased steadily, despite the rupture of his party, which he reconstructed at the conference of Nagyvárad (March 17, 1868), when the famous *Bihari pontok,* or articles of Bihar, were subscribed, which bound the Tisza party to repeal all laws or institutions contrary to, and to promote all measures necessary for, the national independence Thus the delegation system and the common ministries were marked out for attack, while every effort was to be made to procure for Hungary a separate army, a separate diplomacy and a separate financial system. It was chiefly owing to the efforts of Tisza and his party that Austria remained neutral during the Franco-German War. In 1875 his party amalgamated with the followers of Deák into the *Szabadelvu párt* or Free Principles Party, which took office under Bela Wenckheim (1811–1879), whom (Oct. 2) Tisza succeeded as prime minister, a post he held, with a few interruptions, for the next 15 years In 1879 he materially contributed to the formation of the Austro-German alliance. Not till 1888, when the national army bill was introduced, did he encounter any serious opposition, but thenceforth his position became precarious, and he resigned office on March 13, 1890 It was owing to his influence, above all things, that Hungary acquired a consolidated government and a position of predominance in the dual monarchy It is an open secret that, on the retirement of Andrássy, he was offered the chancellorship He refused it because, to use his own expression, "I am as wholly and solely Hungarian as the river (Theiss, Hung *Tisza*) whose name I bear"

See G. Gratz, *Kálmán Tisza* (*Modern Magyar Statesmen,* I) (Hung; 1902); P Busbach, *The Last Five Years* (Hung; 1895).

TITANIC, LOSS OF THE, at 2 20 A M. on April 15, 1912, the White Star liner "Titanic," at that time the largest ship afloat, on her maiden voyage, went to the bottom of the Atlantic after striking at full speed on an iceberg, with a loss of 1,513 souls out of 2,224 on board. The full record of the disaster is contained in the reports of the inquiries held at once in America by a committee of Congress under Senator Smith, and later in London by a special commission presided over by Lord Mersey (report issued July 30)

See British Parliamentary Papers No 2253, *Shipping Casualties* (*Titanic*) 1912 (ed 6352).

TITANIUM (symbol Ti, atomic number 22, atomic weight 48·1). In a substantially pure state, titanium has a very restricted commercial application. The method adopted by Hunter is the standard one for the production of the pure element, but an impure product may be obtained from the dioxide by the application of Goldschmidt's thermit reaction (*see* below) or by reduction with carbon in the electric furnace. Pure titanium is silver-white with a fracture similar to that of steel It is hard and brittle when cold, but at a low red heat it is malleable and can be forged readily like iron. The specific gravity is 4.5 and the melting point, according to Hunter, 1850°C. It is soluble in dilute sulphuric acid, in hot concentrated hydrochloric acid and in *aqua regia,* whilst hydrofluoric acid readily dissolves it. It combines with nitrogen with avidity. With oxygen and the halogens, compounds of quadrivalent titanium are produced.

The existence of the element known as titanium was discovered in 1789 by the Rev. William Gregor during an investigation of a peculiar black sand found at Menachan in Cornwall. This black mineral he called menachanite (or meccanite) and the new element he named menachite Four or five years later, the German chemist, Klaproth, discovered a new metal whilst investigating the composition of the mineral rutile. On account of the strength of the chemical combination in which it was held, he gave to the new element the name titanium—an allusion to the Titans of Greek mythology, the incarnation of natural strength. In 1797 Klaproth investigated the mineral ilmenite—which was identical with menachanite—and recognized that titanium and the menachite of Gregor were identical Nevertheless, titanium is the name which is now universally adopted for the element. Attempts to isolate titanium were first made by Lampadius in 1797 and later by Berzelius and other investigators The metallic-looking products isolated by early investigators were generally nitrides or carbides, for titanium has a pronounced affinity for oxygen, carbon, and nitrogen. In 1895, Moissan published an account of his experiments on the reduction of titanium dioxide with carbon at the temperature of the electric furnace. His final product was free from nitrogen and silicon but contained about 2% of carbon, probably as the carbide This was the purest titanium isolated till the work of Hunter in 1910, who adopted a method previously used, unsuccessfully, by Nilson and Petterssen By heating titanium tetrachloride with sodium in an air-tight steel cylinder, with exclusion of air, Hunter obtained titanium nearly 100% pure.

Although frequently regarded as one of the rare elements, titanium occupies the ninth place in Clarke's table of the estimated abundance of the elements in the earth's crust This table discloses the interesting fact that titanium is more abundant than such common elements as carbon, phosphorus or sulphur, and much more abundant than the useful metals, lead, copper and zinc There is, however, a distinctive difference between the mode of occurrence of titanium and that of these other metals, for whereas the greater part of the titanium is so widely diffused through the earth's crust as to make its recovery economically impossible, the less abundant metals are concentrated in segregated deposits (mineral veins, lodes, etc) capable of satisfactory exploitation Hence, of all the numerous titanium-bearing minerals, only three or, at most, five are entitled to be classed as possible ores of titanium. They are rutile (TiO_2), ilmenite ($FeTiO_3$), titaniferous magnetite (magnetite is Fe_3O_4), and possibly titanite ($CaO{\cdot}TiO_2{\cdot}SiO_2$) and perovokite ($Ca,Fe''$) TiO_3 Rutile occurs in igneous, in metamorphic, and in sedimentary rocks, and its mineral associates include a wide range of species Although widespread in occurrence, deposits of commercial importance are few in number and, so far, restricted to certain localities in the United States, Canada, Norway and South Australia Rutile crystallizes in the tetragonal system, commonly as short, stout prisms or elongated prisms frequently showing striated prism faces. It is normally reddish-brown to red, the specific gravity of the ordinary red variety being 4 18 to 4 25 Titanium dioxide contains 60% of titanium and 40% of oxygen Actually, the mineral usually contains from 54 to 59% of titanium with minute quantities of vanadium and iron Rutile is infusible before the blowpipe and insoluble in acids, but fused alkalis and alkali carbonates bring it into solution Ilmenite crystallizes in the hexagonal system as rhombohedra, but it is rarely seen as good megascopic crystals. Commonly it occurs as embedded grains and masses, whilst it may also be found as a sand. The mineral is iron-black with a metallic lustre. Although it is customary to assign to it the formula $FeTiO_3$, numerous analyses indicate the formula $FeTiO_3,xFe_2O_3$ whilst others correspond to neither formulation. Ilmenite is both cheaper and more plentiful than rutile, and probably the most extensive deposits of the mineral are those of the province of Quebec, Canada, and the Ekersund-Soggendal district of Sweden Other important deposits are found in the United States and South Australia, whilst ilmenite is a by-product from the crude monazite sands of Ceylon and Travancore, India. For industrial purposes the only distinction between ilmenite and titaniferous magnetite is in the titanium

content. Ore, classed as ilmenite, has a titanium content of 18 to 24% or more, whilst titaniferous magnetite seldom carries more than 15% of titanium.

Although titanium is unimportant commercially, yet when alloyed with other elements it forms a number of useful products. Four of these alloys—ferrocarbon titanium, carbon-free ferrotitanium, cuprotitanium, and manganotitanium—are in commercial use Ferrocarbon titanium is made by reduction of ilmenite with coke in an electric furnace, or by charging rutile mixed with carbon into an electric furnace containing molten iron or steel. The alloy so produced has a high carbon content (5 to 8%) but this can be reduced below 1% by remelting with rutile Ferrocarbon titanium normally contains Ti 15—18, C 7, Si 1·5%, the rest being iron and small quantities of impurities. The carbon-free ferrotitanium is produced by the thermit process. The finely-powdered ilmenite (or oxides of iron and titanium) mixed with aluminium powder, in the correct proportions, is ignited by means of a fuse. A rapid reaction takes place in which the oxides are reduced to the elemental condition and an alloy of the following composition is produced: Fe, 67—69; Ti, 25; Al, 5—6; Si, 1—1 05; P, 0 05; S, 0.01%. Cuprotitanium is made by the alumino-thermic reduction of rutile to which copper has been added, and manganotitanium is similarly produced by the reduction of rutile to which manganese or its oxide has been added. Titanium in the form of its alloys acts as a final deoxidizer and denitrogenizer for metals The addition of the ferro-alloys to steel yields a cleaner and sounder product, whilst the cuprotitanium and manganotitanium are used as deoxidizers in brass and bronze practice Titanium in the form of its compounds finds many useful applications Ilmenite and rutile, as well as artificial titanium dioxide, have been used in the making of arc-lamp electrodes. Titanium compounds have proved of value as pigments in the paint industry, dyes and mordants in the textile and leather industries, refractory colouring materials for use in ceramics and in the manufacture of artificial teeth. Titanium white, TiO_2, is put on the market as a pigment to compete with white lead and zinc white.

Titanium forms a wide range of salts in which it exhibits valencies of 4, 3, and 2. Titanium tetrachloride, $TiCl_4$, which may be conveniently prepared by passage of chlorine over heated titanic oxide (TiO_2) and carbon, is a colourless liquid boiling at 136·4° C. It fumes excessively in the air and was used as a smoke-screen during the World War By electrolytic reduction of a solution of the tetrachloride in hydrochloric acid, a violet solution of titanium trichloride is obtained. This compound has pronounced reducing properties and has been utilized for many useful volumetric processes (Knecht and Hibbert, *New Reduction Methods in Volumetric Analysis,* 1910). Salts of quadrivalent titanium are normally colourless, but the titanous salts, containing tervalent titanium, are generally violet or green, and include some powerful mordants which produce brilliant and stable colours, *e.g*, $Ti_2(SO_4)_3,Na_2SO_4,5H_2O$. Hydrogen peroxide gives with titanium salts a yellow to brown coloration due to the formation of pertitanic acid, TiO_3,xH_2O

TITANOTHERIA, an extinct family of hoofed, herbivorous mammals remotely allied to the horses, tapirs and rhinoceroses and ranging from the Lower Eocene to the close of the Lower Oligocene in North America, to the Middle or Upper Oligocene in Mongolia. The earlier members of the group were small and hornless but these gradually gave rise to huge animals surpassing the existing rhinoceroses in size and characterized by the presence of a transversely placed pair of large horn-like outgrowths above the nose. For the origin of the group, *see* PERISSODACTYLA.

TITANS, in Greek mythology, the children of Uranus (Heaven) and Ge (Earth). The Greek name is Τιτᾶνες, the etymology of which is uncertain According to Hesiod (*Theog.,* 133), the male Titans were Oceanus, Cocus, Crius, Hyperion, Iapetus and Cronus; the female, Thea, Rhea, Themis, Mnemosyne, Phoebe and Tethys. Later authors add other names. After the rebellion of Cronus and the birth of Zeus (*see* CRONUS), a struggle ensued between Zeus and Cronus in which the Titans nearly all sided with the latter, but were finally defeated, and imprisoned in Tartarus (Hesiod, *Theog.,* 153–210, 617 et seq.).

The standard work on the subject is M. Mayer, *Die Giganten und Titanen in der antiken Sage und Kunst* (1887); *see* also the classical dictionaries *s.v.*

TITCHENER, EDWARD BRADFORD (1867–1927), Anglo-American psychologist, was born on Jan. 11, 1867, in Chichester, England, possibly a descendant of John Tychenor (1532) of Chichester. For four years he attended Malvern college in Worcestershire, and then at the age of 18 (1885) he became a member of Brasenose college at Oxford. Here for four years more he was senior scholar in classics and philosophy and senior Hulmean exhibitioner. In his fifth year at Oxford he was a research student in physiology under Burdon-Sanderson, to whom he later acknowledged an intellectual debt. At this time physiological psychology as a laboratory science was just becoming established in Germany and America, and Titchener, trained in philosophy and physiology, turned to the new science and went to Wundt (*q.v*), the "founder" of experimental psychology, at Leipzig, where was the first and the leading psychological laboratory Here he received his Ph.D. degree in 1892 Then, with the Wundtian impress upon him, in the days when psychological laboratories were still rare, he accepted the post in the laboratory at Cornell university, Ithaca (N.Y), where he remained until his death 35 years later His chief work is the *Experimental Psychology,* the most thorough and extensive encyclopaedic handbook of experimental psychology that has been written in English. The first two volumes, covering qualitative psychology, appeared in 1901; the third and fourth volumes, treating of quantitative psychology or psychophysics, were published in 1905

In America, Titchener always represented the Wundtian traditions, he never became part of the American trend in psychology, a trend that emphasizes individual differences among persons and the application of psychology to human welfare Titchener stood for the "pure" scientific psychology of the generalized, normal, adult mind In the early days he thus became the exponent of the school of structural psychology which opposed functional psychology; in later times he represented the opposition to behaviourism and to the psychology of mental tests His systematic contributions to theoretical psychology are to be found in his *Lectures on the Elementary Psychology of Feeling and Attention* (1908), *Lectures on the Experimental Psychology of the Thought-Processes* (1909), *Text-book of Psychology* (1910) and, to a less extent, in his *Beginner's Psychology* (1915) He died in Ithaca (N Y), Aug. 3, 1927

See the biographical sketches, under the title "Edward Bradford Titchener," by H C Warren, in *Science,* vol. lxvi. (1927), and by E G Boring in *The American Journal of Psychology,* vol. xxxviii. (1927); also "Titchener at Leipzig," by Frank Angell, in *The Journal of General Psychology,* vol. 1 (1928). (E G. BOR)

TITE, SIR WILLIAM (1798–1873), British architect, the son of Arthur Tite, a Russian merchant, was born in London in Feb. 1798, and died on April 20, 1873. The rebuilding of the Royal Exchange, opened in 1844, was Tite's greatest undertaking He was M P. for Bath (1855–73) and president of the Royal Institute of British Architects (1861–63 and 1867–70).

See *Journal, Royal Institute of British Architects,* pp. 209–212 (London, 1873–74).

TITHES, a form of tribute consisting of a tenth of a man's property or produce, connected politically with taxation, and religiously with the offering of "firstfruits" to deity. This custom was almost universal in the ancient world, and can be traced in Babylonia, Persia, Arabia, Egypt, Greece, Rome and even in China. The tax probably originated in a tribute laid by a conqueror or ruler on his subjects; and we may assume that the custom of dedicating a tenth of the spoils of war to the gods led to a religious extension of the term, the original offerings to deity being "firstfruits." Among the early Hebrews, for example, the king could exact a tithe from cornfields, vineyards, and flocks

(1 Sam. viii. 15, 17); and on the religious side the oldest laws (*e.g.*, Exod. xxxiv. 26) speak of bringing the firstfruits of the land to the house of Yahveh By the 7th century (Deuteronomy) the word "tithe" has come to be used regularly for religious dues. But the analysis of tithe-legislation in the books ascribed to Moses is a complicated problem, owing to the way in which strata of legislation belonging to different periods are combined in the Pentateuch as we now have it; and for detailed investigation reference should be made to the works mentioned below. Ultimately the tithe system became a means of contributing to the regular support of the priests, as ministers of the public ritual.

Tithes in Christendom.—The earliest authentic example of anything like a law of the State enforcing payment appears to occur in the capitularies of Charlemagne at the end of the 8th or beginning of the 9th century. Tithes were by that enactment to be applied to the maintenance of the bishop and clergy, the poor, and the fabric of the church. In course of time the principle of payment of tithes was extended far beyond its original intention. Thus they became transferable to laymen and saleable like ordinary property, in spite of the injunctions of the third Lateran Council, and they became payable out of sources of income not originally tithable.

The Council of Trent definitely enjoined payment of tithes, and excommunicated those who withheld them (Sessio xxv. 12). In England the earliest example of a legal recognition of tithes appears to be in a decree of a synod in 786 (quoted by Selden, *History of Tithes*, ch viii. 2) Other examples before the conquest occur in the laws of Alfred, Athelstane, Edgar, and Canute. It was Selden's denial of the divine right of tithes which brought down the wrath of the Star Chamber upon his head (1618), and he was forced to retract his opinion.

Tithes in English Law.—Two chronological divisions may conveniently be made

(i.) Before the Commutation Acts (1836 *sqq.*). Tithes were classified by origin, as "praedial," or arising immediately from the ground, *e.g.*, grain of all sorts, hay, wood and the like; "mixed," or arising from things immediately nourished by the ground, *e g.*, colts, lambs, eggs and the like; or "personal," namely, of profits arising from the honest labour and industry of man, and being the tenth part of the clear gain, *e g.*, fishing, mills and the like; or according to value, as great, *e g.*, corn, hay and wood; or little, which embraced all others. Of common right tithes were only payable of such things as yield a yearly natural increase and generally only once a year. They were recoverable by a writ against the owner of the tithable property usually brought in the ecclesiastical courts, the jurisdiction of which in this respect was confirmed by the statutes *Circumspecte agatis* (13 Edw. I), *Articuli cleri* (9 Edw II.), and others of Henry VIII. and Edward VI; and an act 2 and 3 Edw VI. made any person refusing to set out tithes liable to pay double the value in the ecclesiastical court or treble in a common law court. At the time of the Commutation Acts, it was common for a tithe-owner to accept a fixed sum of money or fixed quantity of the goods tithable in place of the actual tithes, whether in respect of a whole parish or only of particular lands within it; and this could be sued for in the ecclesiastical courts. In the City of London there were customary tithes; in other towns and places there were compositions for tithes which were confirmed by local acts of parliament; and according to a return presented to the House of Commons in 1831, there were passed between 1757 and 1830 no less than 2,000 local acts containing commutation clauses.

(ii.) The principle of the Tithe Commutation Acts (1836–1860) is to make permanent and general the system which had been only partial or temporary (in most cases), and to substitute a corn rent (known as a tithe rent charge), permanent in quantity and payable in money, but fluctuating in value, for all tithes, whether payable under a *modus* or composition or not, which may have heretofore belonged either to ecclesiastical or lay persons (Phillimore, *Eccles. Law*, ii. 1161). Commissioners (now the board of agriculture) are appointed to execute the acts; a rent charge on all lands liable to tithes at the time of the passing of the first act is substituted for those tithes, of which the gross amount is ascertained either by voluntary parochial agreement, or, failing that, by compulsory award confirmed by the commissioners, and the value of the tithes is fixed in the latter case by their average value in the particular parish during the seven years preceding Christmas 1835, without deduction for parochial or county and other rates, charges and assessments falling on tithes, the rent charge being liable to all the charges to which tithes were liable The rent charge is apportioned on all the lands liable in the parish, and such apportionment may be altered or a new one made, and the value of the rent charge is fixed at the value (at the time of confirmation of the apportionment) of the number of imperial bushels and decimal parts of bushels of wheat, barley and oats as the same would have purchased at the prices so ascertained by the advertisement (of prices of corn) to be published immediately after the passing of the act 6 and 7 Will IV c 71, in case one-third part of such rent charge had been invested in the purchase of wheat, one-third part in the purchase of barley, and the remaining third part in the purchase of oats; and the respective quantities of wheat, barley, and oats so ascertained shall be stated in the draft of every apportionment The price at which the conversion from money into corn is to be made at the time of confirmation of such apportionment, according to the provisions of the said act, are 7s $0\frac{1}{4}$d. for a bushel of wheat, 3s $11\frac{1}{2}$d for a bushel of barley, and 2s. 9d for a bushel of oats (7 Will IV and 1 Vict c 69); the average price of the bushel of each grain is now computed by substituting for the "advertisement" above the statement of the septennial average price of the imperial bushel of British corn made under the Corn Returns Act, 1882; and thus the value of the statutory amount of corn is now fixed for each year at the beginning thereof at the average price of the three components of corn for the previous seven years

The method of recovering rent charge under the Commutation Acts was distraint where the rent charge is in arrear for 21 days after the half-yearly days of payment, and entry and possession with power of letting if it is in arrear for 40 days. This power of distress and entry extends to all lands occupied by the occupier of the land whose tithe is in arrear as owner or under the same landlord; but no action lies against the owner or occupier of the land personally. If a tenant quits leaving tithe unpaid, the landlord may pay it and recover it from him. The tithe-owner cannot recover damages from the tithe-payer for not cultivating the land Special provision is made for the recovery of the rent charge in railway lands.

The act of 1891 shifted the responsibility from the occupier to the landowner by making the latter solely responsible The landowner became liable to pay the rent charge in spite of any contract to the contrary between him and the occupier; the rent charge if in arrear for three months is recoverable by an order of the county court, whatever its amount may be; if the land is occupied by the owner, the order is executed by the same means as those prescribed in the Tithe Acts; but if it is not, then by a receiver being appointed for the rents and profits of the land Appeal lies to the High Court on points of law, and a remission of rent charge may be claimed when its amount exceeds two-thirds of the annual value of the land. The act does not apply to the particular kinds of rent charges mentioned above.

The Tithe Acts do not apply to the city of London, which has always had its own peculiar customary payment regulated by episcopal constitutions of 13 Hen III and 13 Ric. II and statutes of Henry VIII confirming a decree of the privy council, under which the rate of tithes was fixed at $16\frac{1}{2}$d for every 10s rent, and at 2s. 9d for every 20s rent of houses, shops and the like by the year Provision was made by statute after the fire of London for certain annual tithes to be paid in parishes whose churches had been destroyed, and there have been local acts from time to time with regard to particular parishes therein

TITHING. Formerly throughout England, except in the north and west, every man had to be enrolled in a group of ten men, called a tithing, who were responsible for his appearance in court if he were accused of any offence This was known as the system of frankpledge (*q v.*) If the offender was not forthcoming, enquiry was made whether he was in frankpledge; if he were not, and had no right of exemption, the township was amerced, but if he were in a tithing, then it was upon the tithing that the amercement fell South of the Thames the tithings were districts normally identical with the township which discharged the duties of the frankpledge. Some townships, however, contained more than one tithing There are also indications that in the ancient kingdom of Mercia the tithing was originally a district and not a mere association of persons.

TITHONUS was, in Greek legend, according to Homer, the son of Laomedon, king of Troy and husband of Eos (the Dawn) In the Homeric *Hymn to Aphrodite* Eos is said to have carried him off because of his great beauty. She entreated Zeus that he might live for ever, this was granted, but she forgot to ask for immortal youth for him. He became a hideous old man; Eos then shut him up in a chamber; his voice "flowed on unceasingly," but his limbs were helpless.

A later development is the change of Tithonus into a grasshopper, after Eos had been obliged to wrap him like a child in swaddling-clothes and to put him to sleep in a kind of cradle In some versions she is said to have carried him away to the land of Ethiopia near the ocean streams

See O. Gruppe, *Griechische Mythologie*, i 313, n. 16, who attributes a Milesian origin to the story; also the classical dictionaries

TITI, a name properly applied to the small South American monkeys of the genus *Callicebus*. The titis, of which there are numerous species, inhabit the forests of Brazil and the neighbouring countries and feed on fruits, insects and even small birds. The tail is long and bushy, and is not prehensile They are very vociferous, though less so than the howler monkeys (*q v.*) of the same region. The name titi (also spelt teetee) is also sometimes used for the spider-monkeys (*Saimari*), small, richly coloured, largely insectivorous forms, inhabiting Central and South America. (*See* SPIDER-MONKEY.)

TITIAN (*c.* 1477–1576), Tiziano Vecellio, or Vecelli, one of the greatest representatives of the Venetian school of painting. The house at Pieve di Cadore where he was born is now a small museum. Titian, one of a family of four, was the son of Gregorio Vecelli, a distinguished councillor and soldier, and of his wife Lucia. The date of his birth is generally given as 1477. Vasari in one passage (at variance with Ridolfi) says that Titian was born in 1480; while Titian himself, writing to Philip II. in 1571, professed to be ninety-five years old.

He was still a child when sent by his parents to Venice, to an uncle's house There, according to Lodovico Dolce, he was placed under Sebastiano Zuccato, a mosaicist and painter He next became a pupil of Gentile Bellini, and then of Giovanni Bellini. The youth was a contemporary of Giorgione and Palma Vecchio, who influenced him at first; when his period of pupilage expired, he is surmised to have entered into a sort of partnership with Giorgione. A lost fresco of "Hercules" on the Morosini Palace is said to have been one of his earliest works. In 1507–1508 Giorgione was commissioned by the state to execute frescoes on the re-erected Fondaco de' Tedeschi (warehouse for the German merchants). Titian worked along with him, as is known to us only by engravings. Towards 1511, Titian went to Padua, and painted in the Scuola di S. Antonio a series of frescoes, representing the life of the saint. Another fresco, dated 1523, is "St. Christopher carrying the Infant Christ," at the foot of the staircase in the ducal palace of Venice. From Padua Titian in 1512 returned to Venice; and in 1513 he obtained a broker's patent and became superintendent of the government works, being charged to complete the paintings left unfinished by Giovanni Bellini in the hall of the great council in the ducal palace (destroyed by fire). He set up an atelier on the Grand Canal, at S. Samuele. It was not until 1516, upon the death of Bellini, that he came into actual enjoyment of his patent, which yielded him an annuity of 120 crowns—and exempted him from certain taxes—he being bound in return to paint likenesses of the successive doges of his time at the fixed price of eight crowns each The actual number which he executed was five. The year 1516 witnessed Titian's first journey to Ferrara. Two years later was completed, for the high altar of the church of the Frari, one of his most world-renowned masterpieces, the "Assumption of the Madonna." It excited a vast sensation.

Titian was now at the height of his fame; and in 1525, he married a lady of whom only the Christian name, Cecilia, has come down to us; he hereby legitimized their first two children Pomponio and Orazio. Pietro Aretino, the literary bravo, of influence and audacity, arrived in Venice in March 1527 and soon became intimate with Titian who sent a portrait of him to Gonzaga, duke of Mantua, in June 1527 In 1530 he painted in Bologna a portrait of the emperor Charles V, and was created in 1533 a count palatine and knight of the Golden Spur, his children also being made nobles of the empire—for a painter, honours of an unexampled kind.

The Venetian government, dissatisfied at Titian's neglect of the work for the ducal palace, ordered him in 1538 to refund the money which he had received for time unemployed; and Pordenone, his formidable rival of recent years, was installed in his place At the end of a year, however, Pordenone died; and Titian was reinstated after having applied himself diligently to painting in the hall Barbarossa's Victory at Spoleto, erroneously referred to as Battle of Cadore. This great picture, which was burned with several others in 1577, represented in life-size the moment at which the Venetian captain, D'Alviano, fronted the enemy, with horses and men crashing down into the stream Fontana's engraving, and a small copy in the gallery of the Uffizi in Florence, record the energetic composition A visit was paid to Rome in 1546, when he obtained the freedom of the city and painted the portrait groups of Pope Paul III and his two grandsons, the Cardinal Alessandro and the duke Ottavio Farnese. The picture now at Naples was left unfinished and Titian returned to Venice in the same year. In Jan. 1548 and again in 1550–51 he went to Germany to paint Charles V. and others, in Augsburg He executed the portraits of the elector of Saxony (Vienna) and of Philip II. (now lost; copy in Madrid), which was sent to England and proved a potent auxiliary in the suit of the prince for the hand of Queen Mary. In 1554 his beloved daughter Lavinia, whom he painted various times, married Cornelio Scarcinelli of Serravalle; she had succeeded her aunt Orsa, now deceased, as the manager of the household, which, with the lordly income that Titian made, was placed on a corresponding footing. She died in childbirth in 1560. With his European fame, Titian is the last man one would suppose to have been under the necessity of writing letters for payment, especially when the defaulter addressed was lord of Spain and of the American Indies; yet he had constantly to complain that his pictures remained unpaid for and his pensions in arrear, and in the very year of his death (February) he recites the many pictures which he had sent within the preceding twenty years without receiving their price In fact, there is ground for thinking that all his pensions and privileges, large as they were nominally, brought in but precarious returns. It has been pointed out that in the summer of 1566 (when he was elected into the Florentine Academy) he made an official declaration of his income, and put down the various items apparently below their value, not naming at all his salary or pensions. Possibly there was but too much reason for the omission.

In September 1565 Titian went to Cadore and designed the decorations for the church at Pieve, partly executed by his pupils. One of these is a Transfiguration, another an Annunciation (now

in S. Salvatore, Venice). He continued to accept commissions to the last. He had selected as the place for his burial the chapel of the Crucifix in the church of the Frari; and, in return for a grave, he offered the Franciscans a picture of the "Pietà." This work he nearly finished; but some differences arose regarding it, and he then settled to be interred in his native Pieve. Titian was about ninety-nine years of age when the plague, which was then raging in Venice, carried him off on Aug 27, 1576. He was buried in the church of the Frari, as at first intended, and his "Pietà" (now in the Venice Academy) was finished by Palma Giovane, who at that time was his assistant. He lies near his own famous painting, the "Madonna di Casa Pesaro." No memorial marked his grave, until by Austrian command Canova executed a monument. Immediately after Titian's own death, his son and assistant Orazio died of the same epidemic His sumptuous mansion was plundered during the plague by thieves

Titian's portrait of himself in the sixties is at Berlin; Madrid has his portrait as an old man of 80. He was highly distinguished, and a fine speaker, enjoying (as is said by Vasari, who saw him in the spring of 1566) health and prosperity unequalled. He was patronised by the Estes, the Gonzagas, the Medicis, the Farneses. He was favoured by Charles V and by Philip II He gave splendid entertainments; and it is related that, when Henry III. of France passed through Venice on his way from Poland to take the French throne, he called on Titian with a train of nobles, and the painter presented him as a gift with all the pictures of which he inquired the price He was not a man of universal genius, like Leonardo da Vinci and Michelangelo; his one great and supreme endowment was that of painting. He carried to its acme the great colourist conception of the Venetian school.

Titian's pictures abound with memories of his home-country and of the region which led from the hill-summits of Cadore to the queen-city of the Adriatic. He was almost the first painter to exhibit an appreciation of mountains, mainly those of a turreted type, exemplified in the Dolomites. Indeed he gave to landscape generally a new and original vitality, expressing the quality of the objects of nature and their control over the sentiments and imagination with a force that had never before been approached. The earliest Italian picture, expressly designated as "landscape" was one which Titian sent in 1552 to Philip II His productive faculty was immense, even when we allow for the abnormal length of his professional career

The later pictures were painted loosely, telling well from a distant view He himself averred that after his visit to Rome in 1546 he had greatly improved in art; and in his very last days he said that he was then beginning to understand what painting meant In his earlier pictures the gamut of colour rests mainly upon red and green, in the later ones upon deep yellow and blue. Palma Giovane records that Titian would set pictures aside for months, and afterwards, examining them with a stern countenance, as if they were his mortal enemies, would set to work upon them like a man possessed, also that he kept many pictures in progress at the same time, turning from one to the other, and that in his final operation on pictures of the last period he worked far more with finger than with brush Michelangelo's verdict after inspecting the picture of "Danae in the Rain of Gold," during Titian's stay in Rome, "That man would have had no equal if art had done as much for him as nature," has often been quoted He was thinking principally of draughtsmanship, for he added, "Pity that in Venice they don't learn how to draw well." However, as a draughtsman of the human figure Titian was competent and fine, and he is reported to have studied anatomy. His rendering of the nude was lifelike. He distanced all predecessors in the study of colour.

Titian's son, Orazio, born before 1525, who assisted Titian professionally, became a portrait-painter of mark. He executed a picture in the hall of the great council, destroyed by fire. Several other artists of the Vecelli family followed in the wake of Titian. Francesco Vecelli, his brother (d. 1560), was introduced to painting by Titian, and painted in the church of S. Vito in Cadore a picture of the titular saint armed. But he was diverted from painting to mercantile life. Marco Vecelli, called Marco di Tiziano (1545–1611), a distant relation, was constantly with the master, and learned his methods of work. He has left some able productions—in the ducal palace, the "Meeting of Charles V. and Clement VII. in 1529", in S. Giacomo di Rialto, an "Annunciation", in SS Giovani e Paolo, "Christ Fulminant." A son of Marco, named Tiziano (or Tizianello), painted early in the 17th century. There was another relative, Girolamo Dente, who, being a scholar and assistant of Titian, was called Girolamo di Tiziano Various pictures of his were touched up by the master. Apart from members of his family, the scholars of Titian were not numerous; Paris Bordone and Bonifazio were the two of superior excellence. It is said that Titian engraved on copper and on wood, but this may well be questioned He provided drawings for engravers In 1508 according to Vasari appeared the series of woodcuts "Trionfi della Fede" designed by Titian (facsimile reproductions P. Kristeller, Berlin, 1906) A few bold and sketchy pen drawings are extant (Louvre, Uffizi).

We must now briefly advert to Titian's individual works, taking them in approximate order of time, and merely dividing portraits from other pictures. The earliest works which we proceed to mention may date towards 1505 In the chapel of S. Rocco, Venice, is his "Christ Carrying the Cross," now greatly dilapidated; it was an object of so much popular devotion as to produce offerings which formed the first funds for building the Scuola di S Rocco. in the scuola is his "Man of Sorrows" The "Tribute Money" ("Christ and the Pharisee"), now in the Dresden Gallery, dated towards 1508 In the church of S Marcuola, Venice, is the "Christ Child between St Andrew and St Catherine"; in S Marziale the "Tobias and the Angel"; in the Capitoline Museum Rome, "The Baptism of Christ", in the Antwerp Museum, "Pope Alexander VII. presenting Jacopo Pesaro to St. Peter"; in the church of the Salute, Venice, St Mark enthroned, along with SS Sebastian, Roch, Cosmo and Damian Somewhat later, painted after Giorgione's death in 1510 is the famous picture in the Villa Borghese, Rome, commonly named "The Sacred and Profane Love" (c. 1510–12). Towards 1512 was painted the "Three Ages," now in Bridgewater House—a woman guiding the fingers of a shepherd on a reed-pipe, two sleeping children, a cupid, an old man with two skulls, and a second shepherd in the distance—one of the most poetically impressive among all Titian's works, copies of which are in the Doria and Borghese galleries in Rome. Two of the pictures in the National Gallery, London—the "Holy Family With Adoring Shepherd" and the "Noli me tangere"—and the "Salome with the head of the Baptist" in the Doria Gallery, Rome, were going on at much the same time. The great Assumption in the Frari, Venice, painted in 1518, constitutes a landmark in Titian's work Then followed three pictures painted for Duke Alphonso of Ferrara the "Worship of Venus" showing the statue of Venus, two nymphs and many cupids, the "Bacchanal," with Ariadne dozing over her wine-cup, both now in Madrid, and the famous "Bacchus and Ariadne" in the National Gallery, completed in 1522. The "Resurrection of Christ" in S Nazaro e Celso, Brescia, is dated 1522. The "Flora" of the Uffizi and the lovely "Venus Anadyomene" of the Bridgewater Gallery may date a year or so earlier. Another work of 1523 is the stupendous "Entombment of Christ" in the Louvre The picture comes from the Gonzaga collection and from the gallery of Charles I in Whitehall In 1530 Titian completed the "St Peter Martyr" for the church of SS. Giovanni e Paolo; for this work he bore off the prize in competition with Palma Vecchio and Pordenone Of all his pictures this was the most daring in design of action. A fire destroyed it in 1867; the copy of it by Cardi da Cigola has taken its place. To 1530 belongs also the "Madonna del Coniglio" (Louvre), painted for Gonzaga; to 1533 the "St. John the Almsgiver" for San Giovanni Elemosinario, Venice; to about 1538 belongs the "Venus" in the Uffizi, Florence; and the "Venus of Florence"; the portraits of the "Twelve Caesars," for Gonzaga, no longer extant; the "Presentation of the Virgin in the Temple"—one of the conspicuous examples in the Venetian Academy, was finished in 1538. About 1540 were done the forcible paintings for S. Spirito, Venice, now in the church of the Salute—"Cain Killing Abel," the "Sacrifice of Abraham" and "David and Goliath"; in 1543 the "Ecce Homo" of the Vienna Gallery

where Aretino figures as Pilate. The "Venus and Cupid" of Florence, the "Venus" of Madrid and the "Supper of Emmaus" in the Louvre were still in hand, or just completed, when Titian was summoned to Augsburg in 1547. Probably in the forties he also painted the "St John the Baptist" of the Academy at Venice, an impressive figure, classic in conception. In 1554 he sent to Philip II in England a second "Danae" and a "Venus and Adonis." About the same time he sent to Charles V. a "Trinity" (or, as Titian himself termed it, "Last Judgment"), which represented the emperor, with his family and others, all in shrouds, praying to the Godhead. This was the object upon which Charles continued to keep his eyes fixed until the film of death closed on them. A sketch of this picture ascribed to Titian has recently been acquired by the National Gallery, London. Later pictures, from 1558 onwards, are the "Martyrdom of St Lawrence," "Christ Crowned with Thorns" (Louvre), "Diana and Actaeon," "Diana and Callisto," "Jupiter and Antiope," the "Magdalene," "Christ in the Garden," and "Europa"—the last six for Philip II; the two Diana subjects are now in Bridgewater House, "The Europa" in the Gardner collection, Boston The "Jupiter and Antiope," is commonly called "La Vénus del Pardo," having at first been in the Pardo Palace. It was presented to Charles I of England and is now in the Louvre. In 1564 Titian offered to Philip II. his "Last Supper," which had been in hand for six years; it was cut down in the Escorial to suit a particular space The "St. Jerome" of the Brera Gallery in Milan, a work of wonderful energy, spirit and force, was probably rather earlier than this. The last "Madonna" painted by Titian is in the National Gallery (Mond Collection). It is enveloped in golden tone and loosely painted with utmost mastery of the brush "The Christ Crowned with Thorns" in Munich and "The Entombment" in Madrid are powerful, emotional works of his last years Here as in his last work, "The Pietà," his work displays a mystic intensity which contrasts with the superb materiality of his middle period Two of the mosaics in St Mark's church, Venice, namely, the Mark in pontificals and the sword sheathing angel on the right of the high altar, were said to have been worked out after Titian's designs.

We now turn to the portraits—works great in style, stately, and simple in perception and feeling. Among the finest examples are Federigo Gonzaga of Mantua (Madrid), "The Lady at her Toilet," commonly called "Titian and his Mistress" or "Laura Dianti" (Louvre); Francis I (Louvre), painted towards 1536, from a medal, for Titian never saw the French king; various likenesses of himself, one of about 1550, and another of 1562; Paul III. (Naples)—done in about four weeks, was presented to the pontiff in May 1543 and cost two gold ducats; Pietro Aretino (Pitti); Titian's daughter Lavinia (Dresden); the Cornaro Family (Alnwick Castle), "L'Homme au Gant," an unknown personage, youthful and handsome (Louvre); Eleonora duchess of Urbino, Francesco duke of Urbino, Caterina Cornaro queen of Cyprus (these three in the Uffizi); Charles V. on horseback after the battle of Mühlberg painted at Augsburg in 1548 (Madrid) and "Charles seated" executed at the same time (Munich); the portrait of a man called Alexander Medici (Hampton Court Palace); the physician Parma (Vienna) The female portraits done by Titian are few, usually of women of exalted rank The beautiful Flora (Uffizi) and the Bella (Pitti) are among the master's most celebrated pictures Of Ariosto the painter is said to have done three portraits Much uncertainty, however, exists regarding these supposed portraits of Ariosto. One of the three appears as a wood-cut in an edition of the *Orlando furioso* A portrait from Cobham Hall in the National Gallery, London, was wrongly identified with Ariosto

(W M. R; I A R)

TITLE GUARANTEE COMPANIES, the name given to companies which apply the principle of corporate indemnity to the protection of those interested in real estate titles, either as owners or lenders. They are of the class of indemnity companies in which technical skill and experience in investigation of risks are relied upon to protect the guarantor from loss. They are peculiar to countries where the title to real estate is a matter of public record, and where the complexity of the record and the variety of possible liens and encumbrances have made it difficult and expensive to determine whether the title is good. The only country where they have reached large proportions or achieved success as independent business enterprises is the United States In Australia no investigation of a title to real estate is necessary, because before the land passed into individual ownership the government adopted a system of state registration and guarantee of title, so that its certificate of registered title was universally accepted In certain other countries there is neither registration of title nor recording of deeds; the title-deeds are preserved and passed from owner to owner, and are accepted on the authority of the records and opinions of family solicitors. In the United States, however, there have been from the beginning acts providing that all deeds and mortgages be recorded, and the records, when properly made, constitute legal notice to all the world of their contents and claims At the same time, there are other records of wills, suits, judgments, taxes and mechanics' claims which may encumber the title. In the great cities these various records became in course of time so voluminous that the proper investigation of them, and the determination of the validity of the title in view of them, required the best skill of an experienced lawyer and involved very heavy expenses. On a re-sale of the property the new buyer did not rely upon the lawyer who had made the examination for the seller, but felt called upon to employ and pay his own lawyer, who had to go over the same work again, and more, for with each new transaction the history was getting longer The delay and expense involved were great, and yet the owner had little or no protection, for a lawyer is not held to guarantee the correctness of his opinion

The first company actually to undertake the guarantee of real estate titles was formed in Philadelphia, Pennsylvania, in 1876 It differed from the Prussian Mortgage Insurance company (which guaranteed titles merely as an incident in its business as a dealer in, and custodian and guarantor of, mortgages) in that its main business was the issue of a policy of guarantee on a transfer of title to land. The advantages of its method were immediately recognized. Corporations to carry on the business were organized in New York, Washington, Baltimore and Boston, and subsequently in nearly every considerable city in the United States

In order to be independent of the inaccurate and clumsy methods of the public record offices, title guarantee companies generally compile in their own office a copy or digest of all the real estate records of the locality in which they are established, maintaining for this purpose a staff of skilled clerks. To make the necessary examination of a title prior to the issuing of a guarantee, they require continually a body of experienced real estate lawyers. By these means a title can be examined and guaranteed in a week, whereas thirty or forty days was formerly required. This has done much to make real estate available capital, for individual and corporate lenders on mortgage accept the guarantee of the companies as the best evidence of title, and loans can be had without the delay that once prevailed.

The expense of maintaining the staff of clerks and lawyers is great, amounting to half of the gross charges on titles guaranteed. Strictly speaking, the risks outstanding are also large, running up to $100,000,000 a year for a single company in New York city; but in well-managed companies the losses are very small, not exceeding 2% of the gross charges on titles guaranteed, so that the outstanding obligations should scarcely be called risks. In spite of the office expenses, the charges for first bringing a piece of land under the guarantee are no more than owners were in the habit of paying each time for examination and opinion by counsel, amounting to about one-half of 1% on the value of the property or on the amount of the mortgage; and when once the guarantee has been issued, it is re-issued on a subsequent sale or mortgage on short

notice and for a small fee. (C. H. K.)

TITLE INSURANCE or **GUARANTEE OF TITLE,** a term used in the United States for a policy of insurance or a guarantee of indemnity (*see* TITLE GUARANTEE COMPANIES), giving protection and safeguard to an owner of real estate, or a lender of money upon it, against any loss or damage that he might sustain because of any defect in the title prior to the date of the policy, because of the unmarketability of the title or because of any unknown liens or encumbrances against the property, prior to the date of the policy

There are two kinds of property that people use and own—real and personal. Real estate, land, constitutes the real property; stocks, bonds, monies and such movable and chattel holdings are the personal. Personal property can be handled almost at will and in any manner of choice Real estate is immobile. Real property rights and how one may use, own, possess—in fact, employ and enjoy the land he owns, have been safeguarded, restricted and defined in a very prescribed way by law, and custom has also exerted a considerable influence.

In many countries, the ownership of land is restricted to the few There is little incentive and almost no possibility for the general ownership, widespread buying and selling of land. In them, title to real estate is largely a matter of inheritance. Ownership and the matters of title are ascertained from family records, files of title deeds of conveyance, wills and the tradition and general knowledge to be had about the title to the property. Family solicitors have usually handled such matters for generations, taken care of things as they appeared, and upon occasion, given the necessary details and furnished opinions about the title and rights of persons involved In America, however, probably more than in any other country, anyone can acquire land, and the buying, selling and using of real estate as security, are everyday matters.

It is absolutely necessary, however, in any real estate transaction, whether it be a sale, settlement of an estate where there is a division of real property, the lending of money with a real estate mortgage as security, and in fact, in all cases where real estate is involved, to know the condition of the title. It should always be ascertained who owns the property and that there are no adverse claims or owners of interests other than those of the reputed owner, that all taxes are paid or discovered, because any due or unpaid taxes, whether general, State, county, township, or for special purposes such as parks, paving, public improvements, are liens upon the lands against which they are levied; that there are no suits pending, mechanics' liens, judgments rendered in any local court or liens filed by the Federal Government for fines in violation of some Federal statute or unpaid taxes due from the provisions of the Internal Revenue Act which are liens upon the real estate involved; and also that there are no matters in any probate or surrogate court affecting the title It is, therefore, the title to real estate that one acquires or lends money upon, and not the land itself. In order to keep a history or record of the titles to the lands, the United States has what is known as the public recording system. All matters affecting the title to all parcels of land, including transfers, estates, taxes and suits, are entered and recorded in their proper offices and courts of records.

There are two principal kinds of policies, the owner's (or fee) and the mortgagee's policy. The owner's policy guarantees the title to the property and the protection runs to the insured owner or purchaser. The mortgagee guarantees the title to be vested in the mortgagor at the time of making the mortgage; that the indebtedness secured by the mortgage or trust deed is a valid first lien on the property, and upon being transferable to an assignee, insures the validity and genuineness of the assignment of the lien. In case of loss, failure of title or attack it becomes the duty of the title company to indemnify its insured, take over the property or defend the action. The protection of title insurance covers all matters and questions that might be raised about all matters disclosed of record, and in addition things not disclosed or possible to ascertain. These last mentioned include forgeries, frauds, false representations, lost deeds and wills, deeds made by infants, deeds by lunatics, invalid and revoked powers of attorney, claims of undisclosed heirs, mistakes of law, jurisdictional questions, conflict of legal decisions and opinions and many others.

Title insurance is peculiar to the United States because of the facts that the country has a public recording system, that it is not only necessary to ascertain all the minute facts and evidence about the title, but likewise arrive at and secure an opinion as to the sufficiency and legality of each step and matter. Title insurance is a guarantee and protection as to all matters of record, as to the completeness and accuracy of the compiled evidence, as to things not disclosed or ascertainable and the opinion as to their legality and validity. In order to do this, an abstract or history of title is first compiled. This evidence of title is then examined and passed upon by authorities on title law and real estate title matters. Physical examinations and surveys of the premises are also made and the policy then issued. (R B. HA)

TITLES OF HONOUR, "those various names of greatness or eminency, which are the most distinguishing titles of civil dignity" (John Selden, *Titles of Honor*). This definition covers, if we understand "civil" in its proper and widest sense, all titles, whether official or honorary, civil or military, temporal or ecclesiastical In general, however, we now understand by titles of honour what Selden calls "honorary titles," *i e*, distinctive designations implying rank and dignity, not office or vocation. *See* PEERAGE, FORMS OF ADDRESS; EMPEROR; KING; PRECEDENCE, etc.

TITMOUSE (often abbreviated to "tit"), meaning a little mouse, the popular name of any of a number of birds of the genus *Parus*, family *Paridae*, of the order Passeres The genus is usually non-migratory, and is widely spread throughout the world, being found everywhere except in South America and the Australian region east of Flores

The great titmouse or ox-eye (*P maior*) is found all over Europe and north Asia It is conspicuous by its black head, white cheeks and yellow breast with a black band down the centre. Its love-note resembles the noise made in sharpening a saw. Equally widely distributed and even more common is *P coeruleus,* the blue titmouse, with a plumage of blue and yellow Not dissimilar are the coal-titmouse (*P. ater*), distinguished by its black cap and white cheek and nape, and the marsh-titmouse (*P. palustris*), which is more soberly coloured The crested titmouse (*P cristatus*) inhabits the mountain pine-woods of Scotland and Europe generally The most familiar American form is the chickadee (*q v.*) or black-capped titmouse (*P. atricapillus*), but other species of the genus *Parus* and the allied genera *Psaltriparus* and *Auriparus* occur.

During most of the year, the various species associate in family parties, only breaking up into pairs to breed Composite bands of several species are often to be seen during the winter. The nests are placed in hollow stumps, holes in walls or similar situations and have a thick lining of feathers and hair. The eggs, often eight or nine in number, are white, freckled with rust colour. Of a restless disposition, the birds feed largely on insects, but in winter will readily eat suet, coco-nuts and seeds, particularly those of the sunflower. By their destruction of harmful grubs, these birds are of incalculable value to the gardener.

BY COURTESY OF NATIONAL ASSOCIATION OF AUDUBON SOCIETIES

TUFTED TITMOUSE (P BAEOLOPHUS) OF THE UNITED STATES

The allied genus *Acredula* includes the long-tailed titmouse (*A caudata*), which has a tail longer than itself and builds a beautiful oval nest of lichen, moss and wool lined with feathers. Over 2,000 feathers have been taken from one nest When the female is brooding her tail is bent over her back and protrudes at the nest entrance.

The bearded titmouse, reedling or reed-pheasant (*Panurus biarmicus*) inhabits reed-beds. It belongs to a different family, the *Panuridae*.

TITTONI, TOMMASO (1855–), Italian politician, was born in Rome and educated at Naples, Oxford and Liége. In 1886 he was elected deputy for Civitavecchia and in 1902 was raised to the Senate. He was foreign minister for the second Giolitti cabinet (1903), and in this capacity he aimed at improving relations with Austria. On the resignation of Giolitti in March 1905, Tittoni became interim premier for a few days and remained in the Fortis cabinet as foreign minister. His proposed reduction of the duty on Spanish wines in connection with an Italo-Spanish commercial treaty aroused much indignation and caused the fall of the cabinet on Dec 24, 1905 In March 1906 he was appointed ambassador in London, but on the return of Giolitti to power in May, he returned to the *Consulta*, and there continued the policy of improving relations with Austria. In April 1910 he was appointed ambassador in Paris. When the World War broke out, in spite of his Triplicist policy, he openly expressed himself in favour of Italian neutrality. In Nov. 1916 he resigned from the Paris embassy. In June 1919 Nitti chose Tittoni as foreign minister and first delegate at the Peace Conference, but he was forced to resign owing to ill-health in November. He was chosen president of the Senate in December, and was later appointed Italian delegate on the Council and Assembly of the League of Nations, but ill-health again forced him to relinquish the latter appointment. On the advent to power of Fascism he supported the new Government, without joining the Fascist party

TITUS, like Timothy, in the New Testament, is known from allusions in the Acts of the Apostles and the Pauline epistles He was a convert from paganism, and St. Paul refused to allow him to be circumcised (Galatians ii 1 *seq.*) at Jerusalem, when the conservative party demanded this concession to religious feeling. He then appears in connection with the Corinthian church (*see* the Corinthian epistles), where he won the highest praise from the apostle for his upright and loyal services. He was specially entrusted with the business of organizing the collection for the poor Christians of Judaea, in the Achaian churches (2 Cor. viii. *seq.*), and evidently acted as a commissioner of the apostle Paul at Corinth during the dispute which followed According to 2 Tim. iv. 10 he went off subsequently on a mission to Dalmatia, but the Epistle addressed to him implies a tradition that he superintended the work in the island of Crete, as a delegate of his chief. Later tradition made him bishop of Crete. Modern criticism has sometimes identified him with the author of the "We"-journal in Acts, and even thought that he was a brother of Luke (see *Expository Times*, xviii. 285, 335, 380). (J Mof)

TITUS, EPISTLE TO: *see* Pastoral Epistles.

TITUS, FLAVIUS SABINUS VESPASIANUS (A.D. 40 or 41–81), Roman Emperor 79–81, son of the emperor Vespasian, was born on Dec. 30, A.D. 40 (or 41). As a young man he served with credit in Germany and Britain, and had command of a legion under his father in the Jewish War. In 68 he was sent by his father to congratulate the newly proclaimed emperor Galba, but hearing of Galba's death he returned to Palestine. The next year Vespasian, having been proclaimed emperor, went to Italy, leaving Titus to carry on the siege of Jerusalem, which was captured on Sept. 8, 70. On his return to Rome he and his father celebrated a triumph, recorded by the "Arch of Titus." For the rest of Vespasian's reign he was associated with him in the government with the title of Caesar. During this time he was not popular, and he outraged public opinion by his connection with Berenice, sister of Herod Agrippa; both of them came and lived in the palace for a while, but Titus had to send her back. He succeeded his father in 79, and falsified the pessimistic prophecies of his detractors. He put an end to prosecutions for treason, banished the informers, and became *pontifex maximus* to avoid shedding blood. He was notably lenient to Domitian, who plotted against him. The Flavian amphitheatre (Colosseum) was finished in his reign, and he built new baths in Rome. He visited Pompeii when it was destroyed in 79, and contributed to its relief; during his absence there was a three days' fire in Rome, and he again gave his assistance. The empire was peaceful during his reign. The only fighting was in Britain, where Agricola conquered as far as the Tay. Titus died on Sept. 13, 81.

See Suetonius, *Titus;* Dio Cassius lxvi. 18–26; C. Beulé, *Titus et sa dynastie* (1870); L. Double, *L'Empereur Titus* (1877); Merivale, *Hist. of the Romans under the Empire* (ch. 60); H. Schiller, *Geschichte der römischen Kaiserzeit*, i. vol. 2.

TITUS TATIUS, in Roman legend, the Sabine king of Cures, who waged war upon the Romans to avenge the rape of the Sabine women (*see* Romulus). After various indecisive conflicts the latter, who had become Roman matrons, intervened and prevailed upon the combatants to cease fighting. A formal treaty was then arranged between the Romans and Sabines, whereby Romulus and Tatius were to be joint and equal rulers of the Roman people. Rome was to retain its name and each citizen was to be called a Roman, but as a community they were to be called Quirites (*q.v.*); the Sabines were to be incorporated in the state and admitted into the tribes and curies. After this arrangement had lasted for five years it came to an end by the death of Tatius, who was killed out of revenge by the inhabitants of Lavinium. According to Mommsen, the story of his death (for which *see* Plutarch) looks like an historical version of the abolition of blood-revenge. Tatius, who in some respects resembles Remus, is not an historical personage, but the eponymous hero of the religious college called *sodales Titii*. As to this body Tacitus expresses two different opinions, representing two different traditions: that it was introduced either by Tatius himself to preserve the Sabine cult in Rome; or by Romulus in honour of Tatius, at whose grave its members were bound to offer a yearly sacrifice. The *sodales* fell into abeyance at the end of the republic, but were revived by Augustus and existed to the end of the 2nd century A.D. Augustus himself and the emperor Claudius belonged to the college, and all its members were of senatorial rank.

See Livy i. 10–14; Tacitus, *Annals*, i. 54, *Hist.* ii. 95; Dion. Halic. ii. 36–52, Plutarch, *Romulus*, 19–24, Marquardt, *Romische Staatsverwaltung* (1885) iii. 446; Schwegler, *Romische Geschichte*, bk. ix. 3, 14; x 5.

TITUSVILLE, a city of Crawford county, Pennsylvania, U.S A., on Oil creek, 1,180 ft. above sea-level, 42 m S E. of Erie; served by the New York Central and the Pennsylvania railways Pop. (1920) 8,432 (86% native white); 1928 local estimate 10,000 (including immediate suburbs). It is in the oil and gas region of north-western Pennsylvania Development of the field dates from Aug. 27, 1859, when the first artesian oil well in America was drilled just outside Titusville by Col. Edwin L Drake (1819–80), in whose memory a monument was erected in Woodlawn cemetery by Henry H. Rogers in 1902. Under the leadership of John D. Archbold, Titusville was (until 1875) the principal centre in Pennsylvania of opposition to the Standard Oil Company. It was in the Titusville district that the natural gas resources of Pennsylvania were first developed (about 1872). On June 5, 1892, a cloudburst so flooded Oil creek that it wrecked many oil tanks along its banks. The oil caught fire (probably from lightning) and a mass of flames was carried down the creek, causing the loss of 60 lives and great damage to property. Titusville was founded in 1796 by Samuel Kerr and Jonathan Titus. It was incorporated as a borough in 1847 and chartered as a city in 1866.

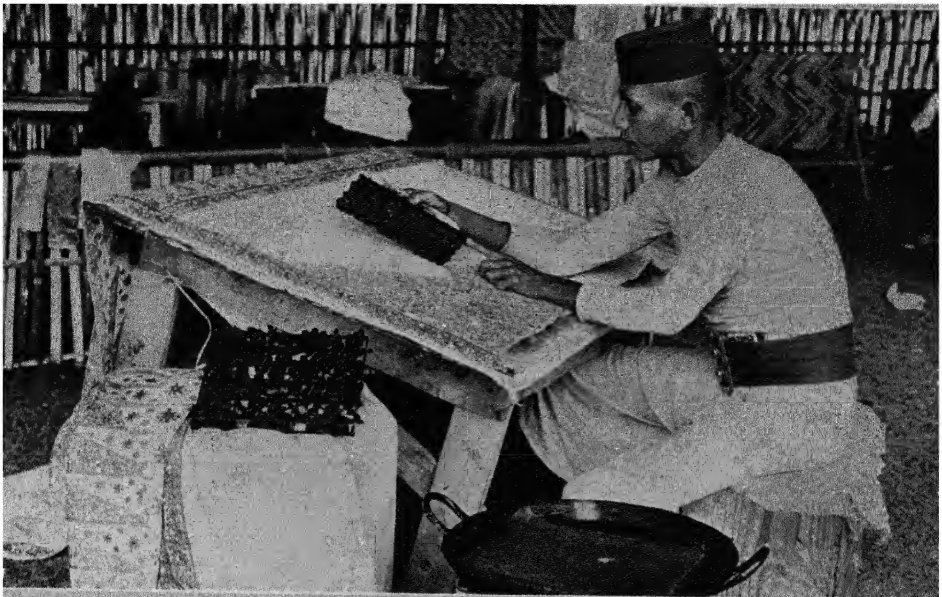
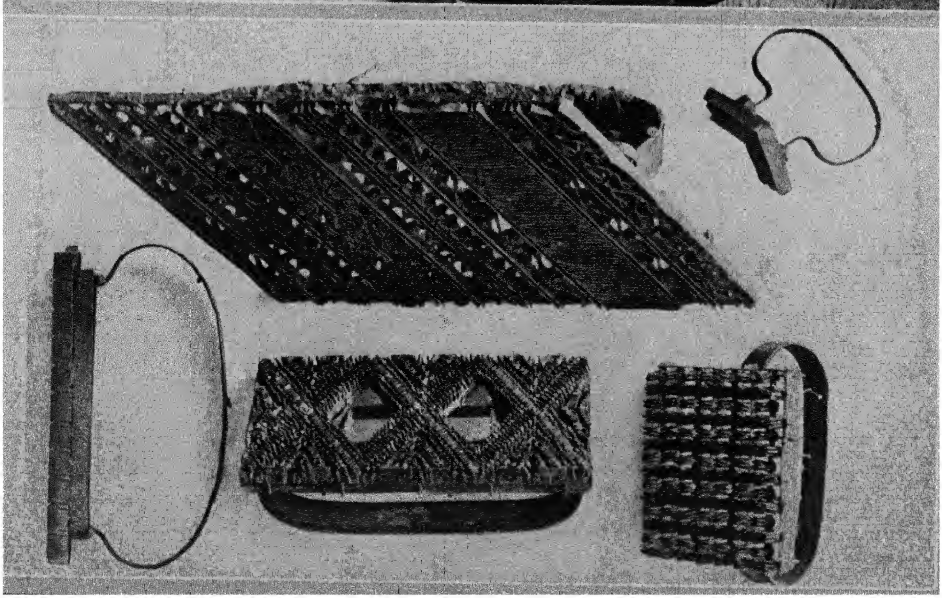
FIRST OIL WELL IN AMERICA, SUNK NEAR TITUSVILLE IN 1859

TIVERTON, a town of Devon, England, at the confluence of the Loman and Exe, 164 m. W. by S. of London by the G.W. railway. Pop. (1921) 9,712. St. Peter's church, originally consecrated as a chapel by Leofric, bishop of Exeter, in 1073, is Perpendicular. Of the original Norman fabric only a doorway remains. Of the castle, founded about 1105 by Richard de Redvers, the banqueting-hall, a tower, the chapel and a 14th-century gateway remain. Blundell's grammar school, founded in 1604, has modern buildings outside the town in Tudor style.

After the decline of its woollen trade Tiverton became noted for the lace manufacture introduced by John Heathcoat (1783–





BY COURTESY OF (2) ROUFFAER AND JUYNBOLL FROM "DE BATIK-KUNST IN NEDERLANDSCH-INDIE" (N. V. A. OOSTHOEK UITGAVE MIT); PHOTOGRAPH, (1) EWING GALLOWAY

TJAPS AND THE METHOD OF APPLYING THEM IN TJAP PRINTING

Tjap printing differs from wood-block printing in that the colours are not applied directly upon the material. The printing surface of the tjaps is first dipped into hot wax and immediately stamped in the desired position on the fabric. When the material is immersed in the dye, its entire surface becomes coloured except those parts covered by the applied wax design. After dying, the wax is removed. In fig. 1 the native craftsman is engaged in stamping the fabric with a tjap block. Fig. 2 shows several tjaps, each of a different design. (*See* Batik)

1861), inventor of the bobbin net frame.

Tiverton is mentioned under the name of Tuyford in the will of King Alfred. In the Domesday survey it appears as a royal manor containing two mills, but it was bestowed by Henry I. on Richard de Redvers, and in 1245 appears as a mesne borough under Baldwin de Redvers. In 1618 the borough received its first charter of incorporation from James I. Fresh charters of incorporation were granted by James II. in 1689 and by George I. in 1724.

See *Victoria County History: Devonshire;* M. Dunsfold, *Historical Memoirs of the Town and Parish of Tiverton* (Exeter, 1790); W. Harding, *History of Tiverton* (1845–47).

TIVOLI (tĭv′ō-lē), (anc. *Tibur*, *q.v.*), a town and episcopal see, province of Rome, 18 m. E.N.E. of Rome by road and tramway, 24½ m. by rail, 760 ft. above sea-level. Pop. (1921), 4,801 (town), 16,389 (commune). Tivoli lies on the west of the Sabine mts., where the river Anio issues from them, upon a limestone rock above the river. The town on one side overlooks the Campagna di Roma and Rome itself, on the other the deep gorge of the Anio, with its lofty falls, and the environs are very beautiful. The Villa d'Este, begun in 1549 by Pirro Ligorio for Cardinal Ippolito d'Este the younger, has the finest example of a Renaissance garden in Italy; it was erected on a steep slope, with many terraces, and embellished with numerous fountains. The castle was built (1460) by Pius II. on the site of the amphitheatre; it is now a prison. The town contains numerous old churches and houses: the cathedral has a fine 12th century campanile, and contains an old copy of the painting of Christ in the Sancta Sanctorum in Rome, S. Silvestro, 11th century paintings; S. Giovanni Evangelista, paintings by an unknown follower of Melozzo da Forlì, etc. In November 1826 a flood of the Anio led to a change in its course, and threatened to carry away the town. A new channel, consisting of two parallel tunnels 290 and 330 yd. long, was therefore made to the north-east in 1826–35, and on emerging from these the river has a fall of 354 ft. Farther north-west are smaller falls (the *cascatelle*) of that portion of the river which is carried through the town and serves for industrial purposes. Five miles W. are the sulphur baths of Acque Albule, which were known to the ancients, and are still frequented. The temperature of the water is 75·2° F. The falls in the river afford electric power for lighting Rome and driving its trams, as well as for driving several factories, etc., in Tivoli itself.

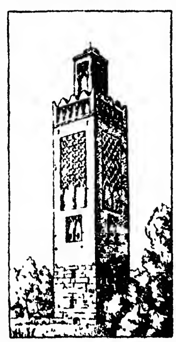
TJAP PRINTING, a kind of block-printing executed by means of dipping blocks into heated wax and then impressing them upon the material—usually a cotton or silk fabric—after which it is dyed and the wax removed, leaving a permanent design. These blocks are made by the natives of Java and the other islands of the East Indies by bending small strips of copper into the desired curves for sections of the pattern and inserting them into the end grain of the blocks of wood allowing them to project a little less than one-eighth of an inch from the surface. The small copper ridges formed in this way are similar to the cloisons which are applied to keep the enamels separated in the decoration of the well-known ware *Cloisonné*. Owing to the fact that it is a very difficult and painstaking task to make these blocks or tjaps the results of this art often bring as high prices as direct hand-work. (*See* BATIK.)

TLAXCALA (tläsh-kah′lah), a State of Mexico, smallest, but most densely populated in the republic, bounded N., E. and S. by Puebla, and W. by the State of Mexico. Area 1,554 square miles. Pop. (1921) 178,570. Tlaxcala lies on the great central plateau of Mexico and has a mean altitude of about 7,000 feet. The State has three railway lines crossing its territory. The capital is Tlaxcala with a population of only 2,069 and no town in the State reaches 10,000. The State nearly coincides with the ancient Indian republic founded in the 13th century by a branch of the Nahuatlan race, who probably migrated from the western shores of Lake Texcoco. Though surrounded on all sides by the great Aztec empire, the tiny republic maintained its independence until the arrival of the Spaniards. The Tlaxcaltecs, or Tlascalans, after a fierce resistance to Cortés in 1519, became efficient allies of the Spaniards and contributed largely to their final success.

TLAXCALA, a town of Mexico, capital of a State of the same name, on the Atoyac river, 7,500 ft. above the sea, 85 m. E. of Mexico City by rail. Pop. (1921), 2,069. Historic interest attaches to the church of San Francisco, the first erected on the American continent, which still contains the vestments, pulpit, font and cedar ceiling brought from Spain in 1521.

TLEMÇEN, a town of Algeria, the capital of an arrondissement in the department of Oran, near the frontier of Morocco, 68 m. by road and 102 by rail S.W. of Oran. It stands 2,500 ft. above the sea, on the north slope of the Lella Setta hills, which rise to a height of 4,000 ft. The railway from Oran runs from Tlemçen to Ujda and is being continued as far as Fez. Another line links Tlemçen to the port of Beni-saf. But, although colonization prospers in the neighbourhood, Tlemçen has lost its former importance; the old capital has become a subprefecture.

The various quarters are grouped around the principal mosque—the Jewish to the south-west, the Moorish to the south-east, that of the merchants to the north-east, while the new town with the civic buildings lies to the north-west. Of the sixty-four mosques which existed at the period of the French conquest, several have disappeared. The great mosque (Jamaa-el-Kebir) has a brick minaret 112 ft. high, adorned with marble columns, and cased with mosaic of the most varied designs; a fountain of alabaster—of the kind known as Algerian onyx—stands in the alabaster-paved inner court; and 72 columns support the arches of the interior. This mosque was built A.D. 1136 to replace a much older building. The *mihrab* is finely ornamented with arabesques. The mosque of Sidi Ahmed bel Hassan, usually called Abul Hassan, built A.D. 1298, now transformed into a museum of antiquities, has two series of arches, which rest on alabaster pillars. The courts are ornamented by sculptures of great beauty and richness; the delicately-carved cedar ceiling bears traces of polychromatic painting. The mosque of El-Halawi (the Sweetmeat Maker), dating from 1353, has eight magnificent columns of Algerian onyx. The ceiling of cedar is richly carved, and there is a fine colonnade on each side of the court. The minaret is decorated with mosaics. The military authorities occupy the Meshuar or citadel, built in 1145, which separates the Jewish and Moorish quarters and was formerly the palace of the rulers of Tlemçen. Only the minaret of the mosque, dating from the 14th century, and the battlemented wall, flanked by two towers, remain of its former magnificence. The vast basin (*sahrij*) under the old walls, now dry (720 ft. in length, 490 in width and 10 in depth), was apparently made for naval exhibitions. A covered market occupied the site of the *Kissaria*, the place of residence of European merchants from Pisa, Genoa, Catalonia and Provence. Besides the large trade carried on there are native manufactories of cloth, carpets and leathern articles. A special manufacture is that of red shawls, used by Jewish women when in mourning.



FROM BENOIT, "ARCHITECTURE ORIENT"

13TH CENTURY MINARET OF THE MOSQUE OF AGADIR NEAR TLEMÇEN

In the immediate neighbourhood of the modern Tlemçen are numerous remains of the fortifications of Agadir (*vide infra*), and the minaret of the mosque, a beautiful tower dating from the 13th century, the lower part of which is built of large hewn stones from the Roman Pomaria. More noteworthy, however, are the ruins of Sidi Bu Medin and of Mansura. Sidi Bu Medin (more properly El Eubbad) is a little over a mile south-east of Tlemçen. It was founded A.D. 1337 by Ali V., the first of the Beni-Marīn (Marinide) sultans who ruled Tlemçen. The *kubba* or tomb of Sidi Bu Medin, near the palace, is held in great veneration by the Arabs. The saint himself was born at Seville A.D. 1126, and died near Tlemçen in his 75th year. The adjacent mosque is a beautiful specimen of Moorish art.

Mansura, which is about 1½ m. west of Tlemçen, owes its foundation to the attempts of the Beni-Marīn rulers of Morocco

to extend their sovereignty The Amir Abu Yakub Yusef besieged Tlemçen in the early years of the 14th century. The siege lasted eight years, and Yusef turned his camp into a walled city. The siege being raised, El Mansura (the victorious), as the new city was called, was abandoned. It was reoccupied when (1335) Ali V. renewed the siege, which this time proved successful. On the expulsion of the Marinides in 1359 Mansura was finally deserted Besides the walls and towers, and the minaret of the mosque, little remains of Mansura, of which Ibn Khaldûn has left a contemporary and graphic sketch. The minaret, notwithstanding that one side and parts of two other sides have perished, is ohe of the finest mosque towers in existence. It is 125 ft high, and is built of hewn stone

See W and G Marçais, *Les monuments Arabes de Tlemçen*, Paris, 1903; A Bel, *Tlemçen et ses environs* (with bibliography), Oron, 1908 (X., A Be)

HISTORY

The Sultanate of Tlemçen.—In 1248 Tlemçen was captured by Abu Yahia Yarmorasen (Ghamarasan) who was chief of the Zenata tribe of Berbers and claimed descent from the Caliph Ali. Yarmorasen, who died in 1282, founded the dynasty of the Abd-el-Wahid, who ruled the greater part of what now constitutes Algeria Under their sway Tlemçen flourished exceedingly The presence of Jews and Christians was encouraged and the Christians possessed a church The bazaar of the Franks (*kissaria*) was a large walled enclosure, the gates of which were closed at sunset. As many as 5.000 Christians lived peaceably in Tlemçen, and the sultan included in his army a Christian bodyguard. In 1337 the power of the Abd-el-Wahid was temporarily extinguished by the Marinide sultans of Morocco They left fine monuments of the period of their ascendancy, which lasted 22 years Once more, under the Abd-el-Wahid, now known as the Beni-Zeiyan, from 1359 to 1553, Tlemçen enjoyed prosperity. It had a population reputed to number 125,000, an extensive trade, a brilliant court and a powerful army The Spanish occupation of Oran (1509) struck a fatal blow at the European commerce of the town. The Beni-Zeiyan, after the capture of Algiers in 1516 by the corsair Barbarossa (*q v*) gradually lost their territory to the Turks, while Tlemçen itself for 40 years became tributary to the Spanish governor of Oran In 1518 the town was held for a short time by Arouj Barbarossa, but Arouj was killed in a fight with the Spaniards

In 1553 the Turks under Salah Rais, pasha of Algiers, captured Tlemçen and the Sultanate of Tagrart, as it was still frequently called, came to an end Under the Turks the town ceased to be of any importance When the French entered Algeria the sultans of Morocco were disputing the possession of Tlemçen with the Kuluglis, who fought first for themselves and afterwards for France. In 1835 Abd-el-Kader, on whose appearance the Moors retired, sought to re-establish the ancient empire of Tlemçen, but he retreated before Gen Clausel in 1836 The Treaty of the Tafna (1837) gave Tlemçen to Abd-el-Kader, but, war being renewed in 1842, Tlemçen was definitely occupied by the French

See W and G Marçais, *Les Monuments arabes de Tlemçen* (1903) This accurate and finely-illustrated work, one of the publications of the *Service des monuments historiques de l'Algérie*, cites the principal works dealing with Tlemçen, and gives a critical estimate of their value *See* also A Bel and P. Ricard, *Le travail de la laine à Tlemçen* (Algiers, 1913). (F. R. C.)

TLINGIT, one of the tribes, or rather assemblages of tribes, of the North Pacific Coast Indians, inhabiting the coastal strip of south-eastern Alaska as far north-west as Controller bay. Their culture is that of the area, with dependence on fishing, canoe navigation, woodworking, totemic art, potlatch wealth distribution and slavery They are divided into Raven and Eagle (or Wolf) moieties, and subdivided into matrilineal clans. The language is superficially distinct, but may prove ultimately to relate with Haida and Athabascan (Na-Dene family) Population, at discovery, estimated 10,000; 1861, 8,600, 1910, 4,400. (A L. K)

TOAD, a name commonly applied, in contradistinction to "frog," to tailless amphibians of stout build, with warty skin. The true toads are the *Bufonidae*, with dilated processes to the sacral vertebra and without any teeth in the jaws. The genus *Bufo* comprises about 100 species; smaller genera are *Eupemphix, Pseudophryne, Nectophryne, Nectes, Notaden, Myobatrachus, Rhinophrynus* and *Cophophryne*. *Bufo jerboa*, in its slender form and long limbs surpasses the typical frogs, whilst on the other hand some true frogs (*Rana*), adapted to burrowing habits, are superficially quite toad-like. The *Bufonidae* include terrestrial, burrowing, aquatic and arboreal types; *Rhinophrynus*, of Mexico, is an ant-eater

The genus *Bufo* is represented in every part of the world except the Australian region and Madagascar Two species are found in the British Isles the common toad, *B vulgaris*, and the more local natterjack, *B calamita*, which has a pale yellow line down its back, and legs so short that it cannot hop, but runs The common American species is *B lentiginosus*, very similar to *B vulgaris* Toads lay their eggs in long strings, forming double files in straight, jelly-like tubes. They feed on worms and insects A small toad, *Pseudophryne vivipara*, discovered in German East Africa, is viviparous (*See* AMPHIBIA)

TOBACCO, the name given to the leaves of several species of *Nicotiana* prepared in various ways mainly for smoking or chewing purposes, and in the powdered form, for inhalation as snuff The use of tobacco is more widely spread than is that of any other narcotic or stimulant

Historical.—The tobacco plant was brought to Europe in 1558 by Francisco Fernandes, who had been sent by Philip II of Spain to investigate the products of Mexico Jean Nicot, the French ambassador to Portugal, sent seeds of the plant to the queen, Catherine de' Medici The services rendered by Nicot in spreading a knowledge of the herb have been commemorated in the scientific name of the genus *Nicotiana* At first almost miraculous healing powers were attributed to the plant, and it was designated "*herba panacea*," "*herba santa*," "*sana sancta Indorum* " "Divine tobacco" it is called by Spenser, and "our holy herb nicotian" by William Lilly.

While the plant came to Europe through Spain, its use for smoking purposes spread to the Continent from England. Ralph Lane, the first governor of Virginia, and Sir Francis Drake, brought to the notice of Sir Walter Raleigh the habit of smoking tobacco Lane is credited with having been the first English smoker, and through the influence and example of the illustrious Raleigh "who tooke a pipe of tobacco a little before he went to

the scaffolde" the habit became rooted among Elizabethan courtiers. During the 17th century the indulgence in tobacco spread with marvellous rapidity through all nations.

Botany.—Few of the numerous species of *Nicotiana* possess any economic importance. The great bulk of the world's tobacco supply is derived from *N. tabacum*, the Virginian tobacco, a plant indigenous to America It is a coarse rank-growing annual, with a simple, unbranched, cylindrical stem, which often exceeds 6 ft. in height. The stem terminates in a panicle of pink or rose-coloured flowers, possessing an elongated corolla tube (fig 1). The plant has alternate, simple, oblong-lanceolate leaves, those at the lower part of the stem being slightly stalked, and of large size, reaching to 2 ft in length, while the upper leaves are semi-amplexicaul and of variable outline. The seeds are brown in colour, with a rough surface, and are so small and numerous that 1,000,000 may be produced by a single plant The stem and leaves of the plant are covered with long soft hairs which exude a viscid juice, giving the surface a moist glutinous feeling

FIG 1—TOBACCO PLANT IN BLOOM

From this species, *N tabacum*, the tobaccos of Cuba, the United States, the Philippines, Canada, Nyasaland, Rhodesia and the Latakia of Turkey are derived, and it is also largely grown in India. the variety *macrophylla* is the source of Maryland tobaccos *N Persica*, regarded as another American variety of this genus, yields the famous Shiraz tobacco of Persia *N rustica* is a smaller branching plant with greenish-yellow flowers, and although a native of Mexico it is much cultivated in the East Indies.

Cultivation.—Tobacco is cultivated in localities scattered over almost the whole world, ranging from as far north as Quebec, Stockholm and the southern shores of Lake Baikal in one hemisphere, to as far south as Chile, South Africa and Victoria in the other While the plant can adapt itself to very varying conditions of climate and soil, the quality and flavour may be seriously deteriorated by unfavourable conditions Very slight differences in climate appear to cause great variation in quality

Given suitable climatic conditions, the type of tobacco produced is determined mainly by the character of the soil, which should be well drained, and contain a large percentage of humus Clay soils, retentive of moisture, as a rule yield heavy-cropping tobaccos which cure to a dark brown or red colour, while sandy soils produce tobaccos with a thin leaf, curing to a yellow or bright reddish colour Cultural details necessarily differ according to the locality, and the type of labour employed, but those prevailing in the United States, the chief source of tobacco may be taken as fairly representative, and are hereafter described

The seed is sown in nursery beds and the plants set out in the field later Great care is taken in the preparation of the seed-bed, which should lie in a sunny situation, protected from winds, and be composed of good, rich soil in fine tilth When necessary hot-beds are used Insect pests are destroyed by burning fires, raised by intervening logs above the surface of the ground, or by steaming the bed Fertilizers, usually guano or chemical manures, are incorporated with the surface soil, which is pulverized to 3 in in depth The seed, owing to its minute size, is usually mixed before sowing with a relatively large quantity of fine ashes, sand or meal, to ensure even distribution. Deep burying of the seed must be avoided, and the young and delicate seedlings carefully watered and if necessary shaded, during the early stages of growth. With seed of good quality a half-ounce of seed is sufficient for a bed of about 60 sq yd., and will yield about 40,000 plants for transplanting

The well hardened seedlings are transplanted into rows from 3 to 4 ft apart, with a distance of from 1½ ft. to 3 ft. between the plants, cigar types being the closer-spaced varieties When the flowering buds appear, these are removed by "topping," and also the suckers which are subsequently produced A limited number of leaves only is allowed to develop, ranging from 8 to 12 in the heavy types and from 15 to 20 or more in cigar wrapper and binder varieties, Burley and Maryland Cultivation under artificial shade has been found beneficial in some districts and this method is used with great success in the Connecticut valley and Florida for cigar wrapper leaf

Ripening is indicated by a change in colour of the leaf from a dark to a lighter shade of green, and by the appearance sometimes also of yellow spots A ripe leaf easily cracks or shows a crease when folded between the fingers The leaves on a plant decrease in age from below upwards, hence all are not ripe at one time. In high quality tobacco the leaves are "primed," or picked singly, as they ripen. The usual course is to cut the whole plants off close to the ground when the middle leaves are about ripe, and allow them to wilt before removal to the drying sheds. Here the plants are supported on laths and the primed leaves on strings or wires until ready for curing

Improvement by Selection.—Plants of the same variety grown under similar conditions reveal differences in such important characters as the number, size and shape of the leaves, tendency to form suckers, time of maturing, and resistance to disease. Variation in burning properties, elasticity of leaf, texture, taste, etc, are also observed The differences are attributed to two factors: (1) variation in type due to crossing, change of soil and climate; (2) variations in type due to inherent tendency, local conditions and maturity of seed

Careful selection is necessary in the choice of plants grown from imported seeds for seed purposes, and only small crops should be grown until the required type has been perpetuated. The tobacco flower is fortunately self-fertile, and hybridization can be avoided by enclosing the selected flowers in paper bags. The pollen also will retain its vitality for several weeks, if kept perfectly dry, and thus can be sent long distances without injury

Further treatment of the tobacco is usually conducted in three stages, known as "curing," "fermentation" and "ageing": on the success of these operations depend the production and fixing of the right colour, and the development of an agreeable aroma in the leaf

Curing.—Sun-curing is employed largely in Eastern countries, but is no longer practised in the so-called sun-cured district of Virginia.

Air-curing is performed in barns provided with a free circulation of air Cigar leaf and White Burley are usually cured thus, the process lasting about six weeks. In both sun- and air-curing the occurrence of damp weather may necessitate the use of fires

In fire-curing, when the tobacco has acquired a rich yellow colour, slow fires are lighted on the floor of the barn to raise the temperature slowly to 150° F and there maintain it for four or five days: re-firing is required at intervals as the leaves again become soft

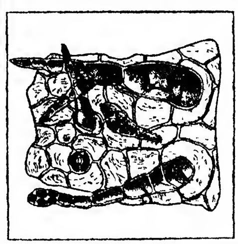

FIG 2—MICROSCOPIC STRUCTURE OF TOBACCO LEAF

The bright yellow leaf used for cut tobacco is cured by flue-heat in order quickly to secure and fix the required shade of colour The heat is steadily raised from 90° F to 160° and even to 180° in the final stages The whole operation lasts from three to five days In the modified process known as the "Kentucky cure," a temperature of not more than 100° F is used, and the process requires from four to six weeks Exposure to a moist atmosphere is in either case necessary to render the leaf sufficiently pliable for stripping and sorting. The tobacco is then made up into bunches or "hands" of from six to twelve leaves by twisting another leaf round the lower end.

Fermentation.—Under favourable conditions, the enzymes naturally occurring in tobacco leaf act on the organic matters present, and the considerable alteration in their chemical constitution, thus caused, exercises a mellowing effect on the tobacco

Changes occur in the nicotine and other nitrogenous constituents, and the starch and sugar bodies disappear, while the colour and aroma of the leaf also benefit by the operation when successfully conducted. Fermentation readily occurs when the tobacco is stacked into heaps, but precautions require to be taken to prevent the temperature rising beyond about 130° F, and the heaps are therefore frequently re-made and re-arranged during the operation which lasts about a month. Flue-cured tobacco is not fermented.

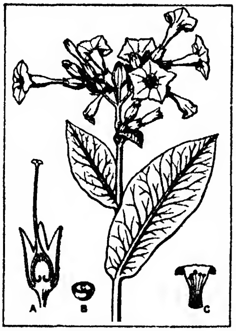

FIG. 3.—TOBACCO PLANT (NICOTIANA TABACUM), FLOWERING BRANCH
A. Longitudinal section through fruit, B. Branch cut across, C. Corolla

After grading, the tobacco is pressed tightly into bales or hogsheads, and stored in warehouses, kept at a moderate and fairly uniform temperature, where it may remain often for several years to mature and complete the "ageing" process, before being manufactured. Further fermentation often spontaneously occurs during this stage. In addition to bales and hogsheads packers make extensive use of boxes or cases, especially for cigar leaf.

Manufacture.—Tobacco is manufactured in various forms for smoking and chewing purposes, including cut smoking mixtures, cake or plug, and roll or spun tobacco. In the preparation of various smoking mixtures, the choice of leaf sufficiently mellowed by age, and the selection of suitable brands of leaf to secure the best results are all important considerations. The tobacco needs damping to render it workable, and this operation is usually conducted on the large scale by passing the leaf through rotating cylinders into which steam is injected.

In Great Britain the legal provisions exist that finished tobacco must contain not more than 32% of moisture, and that no other substance shall be found therein except essential oils for flavouring, and olive oil to the extent of 4%, which may be used only in spinning and making up roll tobacco.

The thick portion of the stalk is as a rule removed before the leaf is cut, except in the case of "bird's eye," to which the sections of cut stalk give its characteristic appearance. The stripped leaves are then pressed into cakes, more or less lightly when intended for shag and similar types, and by means of hydraulic presses when flakes are required. The tobacco is then cut into shreds by machine knives operating with a rapid vertical movement, the speed determining the thickness of the flakes produced. Shags and similar tobaccos are "panned" or roasted, partly to reduce the moisture, and partly to bring out their flavour.

Roll tobacco consists of a filler of broken tobacco which is twisted into a rope and enclosed in a leaf wrapper by means of a spinning wheel. The "brown twist" so produced may be used for chewing purposes, but is usually converted into black or "Irish" roll by coiling the twist into rolls of cylindrical shape, which, after being enclosed in canvas and tightly bound round with rope, are stoved in steam-heated hydraulic presses, and when sufficiently darkened in colour, removed to cold presses to mature.

In cake tobacco the leaves are moulded into shape by pressure, steam presses being used when dark coloured varieties are required. Sweetening materials such as glycerin, licorice and sugar are often added to this class of tobacco, although in Great Britain this practice is restricted to bonded factories.

Snuff.—For light coloured varieties stalks are employed. The distinctive aroma is developed by long periods of fermentation, sometimes after, as well as before, milling. Various salts and essential oils are employed for flavouring purposes, but in Great Britain there are certain legal restrictions regarding their use.

Chemistry of Tobacco.—The nature and proportion of the chemical constituents of tobacco are greatly modified by the compulsory diversion of the life processes of the plant to the sole object of producing leaves suitable for smoking purposes, and also by the changes caused by the curing and fermentation. In addition to containing the volatile alkaloid, nicotine, the characteristic constituent of tobacco, sugar and starch are present in considerable quantities in the bright varieties of leaf, and also salts of such organic acids as acetic, citric, malic and oxalic. In consequence a much higher proportion (about 50%) of the constituents of the leaf is soluble in water than is the case with other plants. The insoluble constituents are made up chiefly of cellulose and pectic acid, which in combination with lime, impart rigidity to the vegetable structure, and of albuminous matter and tannin derivatives.

Leaf tobacco is not usually dried below a moisture content of from 12 to 16%, as too dry a condition causes friability. The amount of nicotine ranges from 2% in bright leaf to 5% or more in dark varieties. The proportion of ash obtained from dry tobacco varies from about 10% in light leaf to 25% in cigar and other dark varieties.

Production.—Production in the various countries is described below in separate paragraphs.

United States.—Tobacco was first cultivated on a commercial scale in Virginia early in the 17th century. It is now grown commercially in eighteen States, the estimated produce for the year 1926 amounting to 1,323,388,000 lb and valued at $248,752,000. The produce of the chief tobacco-producing States expressed in millions of pounds, was as follows, viz., North Carolina (393), Kentucky (374¼), Virginia (132¼), Tennessee (107), South Carolina (57½), Pennsylvania (43½), Georgia (40), Ohio (38), Wisconsin (33¼), Connecticut (29¼), and Maryland (29).

Brazil.—The climate and soil are very suitable for cigar leaf and production is steadily increasing. The crop in 1925 amounted to 139,000,000 lb.

Japan.—The Government monopoly controls the growth of tobacco, and the produce is mostly retained for home use. The crop in 1925 exceeded 132,000,000 pounds.

China.—Production of light cigarette types of leaf of American origin is steadily increasing. Very large quantities of lower grade leaf are also grown, and China is one of the world's foremost tobacco producers.

Dutch Indies.—Sumatran tobacco is especially valued for cigar wrappers. High equable temperatures and a heavy rainfall characterize the eastern coastal growing regions, and very careful attention is paid to the cultivation. The production in 1925 reached nearly 207,000,000 pounds.

Other important tobacco-growing countries outside Europe are as follows. Dominican Republic (45), Mexico (18¾), Persia (23) and Algiers (65)—the figures in brackets indicate the crop in millions of pounds for the year 1925. In the Philippines, where leaf of the cigar type is grown, the production in 1924 was 101,000,000 lb. From Syria comes the characteristic smoke-cured Latakia variety of tobacco.

Europe.—Except in countries bordering on the Levant, where the Turkish type is grown, dark and heavy tobaccos are usually produced. The approximate production, expressed in millions of pounds, for the more important countries was as follows for the year 1925, viz.: Belgium (17), Hungary (38), Germany (42), France (69), Bulgaria (90), Italy (92), Turkey (104), Greece (129) and Russia (204).

British Empire.—A lower rate of duty is charged on tobacco grown in the empire, the amount of this deduction being increased from one-sixth to one-fourth in 1925. Production has been greatly stimulated thereby, the quantities imported into Great Britain at the imperial preference rate of duty having risen from 19,000,000 lb. in 1925 to close upon 41,000,000 lb. in 1927. The chief contributors to this total were as follows: Northern Rhodesia 1,697,214 lb., Southern Rhodesia 9,250,644 lb., Nyasaland, 14,033,665 lb., British India 8,555,111 lb., British North Borneo 1,348,501 lb., Canada 5,619,923 lb.

The increase in empire imports to Great Britain has been accompanied by a decline in imports of foreign origin. Empire imports, which represented only 1% of the total tobacco imports in 1919, amounted to 14·7% of the total in 1927.

Imperial preference at the outset found the British empire

unable to fill the demands of the British market for bright varieties of tobaccos of Virginia type and flavour. Empire production in the year 1920 exceeded 1,071,000,000 lb. and although thus equal to two-thirds of the output of the United States in quantity was not its equivalent in quality. Fully 90% of the Empire produce was grown in India by the aid of native labour, and was of a character suitable only for local consumption. In British Central Africa the possibility of producing acceptable types of tobacco was beginning to be realized. The more liberal tariff concessions granted under the imperial preference scheme in 1925 greatly increased the output of bright American types of leaf in Nyasaland, and brought large areas under cultivation for producing similar kinds of tobacco in Northern and Southern Rhodesia and also in Canada. For the most part the produce of these new sources of supply is either of the bright flue-cured variety suitable for cigarettes, or the darker fire-cured variety for use in smoking mixtures.

It is estimated that the empire production of tobacco in 1927 exceeded 1,100,000,000 lb, the output for the years 1925, 1926 and 1927 was in Canada 20,000,000 lb, 28,824,000 lb. and 43,-916,700 lb, respectively, and in Southern Rhodesia 1,987,382 lb, 5,313,000 lb and 17,000,000 lb respectively.

British consumption of empire-grown tobacco, especially so far as Rhodesian leaf is concerned, has not kept pace with the increased production While Rhodesian tobacco is eminently suitable for employment in cigarettes, it possesses an aroma of a distinctive character which differentiates it from American-grown tobacco The cigarette industry probably absorbs about 70% of the tobacco manufactured in Great Britain In the case of pipe tobaccos it is estimated that about 45% of empire tobacco is used, and 50% in British manufactured cigars.

The production of tobacco in Great Britain, which began early in the 16th century, soon encountered strong State opposition, as it was thought to interfere with the developing export trade from the New England States The growth of tobacco in England was legally forbidden in 1660, but only finally suppressed in 1782 by armed intervention and the imposition of severe penalties.

While the legal restrictions, which extended also to Scotland and Ireland were finally removed in 1910, adverse climatic conditions and other causes have militated against successful production on any considerable scale

World Statistics.—The following details extracted from the International Year Book of Agricultural Statistics (Rome 1927) show the world production of tobacco for the year 1925/6 expressed in thousand pounds Europe (excluding Soviet Russia) 556,600; Asia (excluding Soviet Russia) 287,540; Soviet Russia 389,180; Africa 115,280; North America 1,475,540, South America 193,380; Dutch Indies (culture of Europeans only) 216,000; Oceania 1,540—total 3,235,060 Countries not included would probably raise this figure to nearly 4,000,000,000 lb.

Taxation Methods.—Tobacco provides an important source of state revenue. A government monopoly exists in several European countries, including Austria, France, Hungary, Italy, Portugal, Rumania, Russia, Spain, Sweden, Czechoslovakia, Yugoslavia, and Japan. Taxation is applied to tobacco on importation in the form of a customs duty, usually levied at a lower rate on leaf than on manufactured descriptions, also by means of *ad valorem* duties levied on the retail prices charged. The latter method is usually adopted for raising internal revenue from the home manufactured article. In addition, licence duties for the manufacture and retail of tobacco are usually charged. The tobacco tariffs of the United States, Germany, Belgium and Holland are based on this plan, the lowest duties being placed upon imported leaf, and the luxury descriptions most heavily taxed.

In Great Britain tobacco pays duty in the manufactured state, only when imported or delivered from bonded factories for home consumption. The greater part of the tobacco for home consumption is received from abroad in the form of leaf, and on importation pays a customs duty at the rate of 8s. 10d. per lb., when the moisture present is not below 10%; in order to encourage growth in the empire a rebate of one-fourth of the duty is allowed on such produce. The revenue receipts from tobacco for Great Britain and Northern Ireland amounted to £53,857,530 for the fiscal year ended March 31, 1927.

Consumption of Tobacco.—The comparative consumption of tobacco in various countries is best appreciated by expressing it in pounds per head of the population. The following figures, which except in the case of the United States are approximate estimates, and not officially issued, give details for a few representative countries: viz, Great Britain and North Ireland 2·95 lb., United States 5 92 lb, Belgium 4 9 lb, France 2 9 lb., Italy 2·35 lb., and Egypt 4·76 lb. (*See* also CIGAR; CIGARETTE.)

TOBACCO PIPE. The smoking of tobacco in pipes is a custom which has prevailed in America for a period of unknown duration. The most ancient pipes of which remains exist have been found in mounds or tumuli called pipe mounds, principally in Ohio, Indiana, Illinois and Iowa. These mound pipes, which are carved in porphyry and other hard stones, are very uniform in type, consisting of a slightly convex platform or base, generally from 3 to 4in in length, and about an inch broad, with the bowl on the centre A fine hole is pierced from one end of the platform to the bottom of the bowl, the opposite end being obviously for holding in the hand while the pipe is being smoked. In the commonest forms the bowl consists of a simple cylinder or urn, but in many cases remarkable artistic skill has been displayed in carving the bowls into miniature figures of birds, mammals, reptiles and human heads, often grotesque and fantastic, but always very vigorously expressed These mound or platform pipes with carved human and animal forms are objects of the highest ethnographic interest and importance, being among the most characteristic remains of the ancient inhabitants of the Mississippi valley The wide area over which these, as well as remains of baked clay pipes, are found throughout the American continent testifies to the universal prevalence of smoking in the pre-Columbian era. Many of the ancient clay pipes found in Mexico, etc, are elaborately moulded and ornamented, while others show considerable similarity to the early clay pipes of Europe. Among the North-American Indian tribes the tobacco pipe occupies a position of peculiar symbolic significance in connection with the superstitious rites and usages of the race. The calumet, peace pipe or medicine pipe, is an object of the most profound veneration, entrusted to the care of a highly honoured official, and produced and smoked with much ceremony only on occasions of great importance and solemnity. It is remarkable that, whilst the most ancient American pipes had no separate stem, it is the stem only of the medicine pipe which is the object of veneration among the Indians, the bowl used being a matter of indifference. The favourite material for Indian pipe bowls is the famous red pipe stone (catlinite), a fine-grained, easily-worked stone of a rich red colour from the Côteau des Prairies, west of the Big Stone lake in S. Dakota.

Throughout Great Britain and Ireland small clay pipes are frequently dug up, in some instances associated with Roman relics These are known amongst the people as elfin, fairy or Celtic pipes, and in some districts supernatural agencies have been called in to account for their existence. The elfin pipes have commonly flat broad heels in place of the sharp spur now found on clay pipes, and on that flat space the mark or initials of the maker is occasionally found. There is no reason to believe that these pipes are older than the 17th century. The introduction of the tobacco pipe into Europe is generally ascribed to Ralph Lane, first governor of Virginia, who in 1586 brought an Indian pipe to Sir Walter Raleigh, and taught that courtier how to use it. The pipe-makers of London became an incorporated body in 1619.

By degrees pipes of special form and material have come to be definitely associated with particular peoples, *e.g*, the elongated

painted porcelain bowls and pendulous stem of the German peasantry, the red clay bowl and long cherry wood stem of the Turk, and the very small metallic bowl and cane stem of the Japanese, etc. Among other kinds of pipe which have been popular at various times are the "corn-cob," where the bowl is made of the cob of maize or Indian corn, and the "calabash" with the bowl of a small gourd. The "churchwarden" is a clay pipe with a slender stem, some 16 or 20in long. The most luxurious and elaborate form of pipe is the Persian *kalyún,* hookah or water tobacco pipe. This consists of three pieces, the head or bowl, the water bottle or base, and the snake or long flexible tube ending in the mouthpiece The tobacco, which must be previously prepared by steeping in water, is placed in the head and lighted with live charcoal, a wooden stem passes from its bottom down into the water which fills the base, and the tube is fitted to a stem which ends in the bottle above the water Thus the smoke is cooled and washed before it reaches the smoker by passing through the water in the bottle, and by being drawn through the coil of tube frequently some yards in length The bottles are in many cases made of carved and otherwise ornamented coco-nut shells, whence the apparatus is called *nārgīla,* from *nārgīl,* a coco-nut

TOBAGO, an island in the British West Indies, 20 m. N E. of Trinidad, in 11° 15′ N and 60° 40′ W Pop (1921) 23,390 It is 26 m long and 7½ m broad Area 114 sq m or 73,313 acres, of which about 10,000 are under cultivation It consists of a single mountain mass (volcanic in origin), 18 m long, rising in the centre to a height of 1,800 ft A great part of the island is clothed with dense forest The higher lands are set apart as "Rain Preserve," where trees are not allowed to be felled The average temperature is 81° F and the yearly rainfall is 66 in The rainy season lasts from June to December, with a short interval in September The valleys are adapted to horse- and sheep-breeding The soil is fertile and produces rubber, cotton, sugar, coffee, cocoa, tobacco and nutmegs, all exported; *pimento* (allspice) grows wild The island is divided into seven parishes. Scarborough, the capital, on the S coast 8 m from its SW point, stands at the foot of a hill 425 ft high, on which was situated Fort King George There is a lighthouse at Baedlet Point Tobago, properly Tobaco, was discovered in 1498 by Columbus, who named it Assumption, and the British flag was first planted in 1580 It afterwards passed into the hands of the Dutch and then of the French, and was finally ceded to the British in 1814 It formed part of the colony of the Windward Islands until 1889 when it was joined to Trinidad, its legal and fiscal arrangements, however, being kept distinct Ten years later it was made one of the wards of Trinidad, under a warden and magistrate; its revenue, expenditure and debt were merged into those of the united colony, and Trinidad laws, with some few exceptions, were made binding in Tobago

See Aspinall, *Handbook of the West Indies; Colonial Office List.*

TOBIT, BOOK OF. This book of the Apocrypha is a religious novel which was for many centuries exceedingly popular both in Christian and Jewish circles in many lands. This is shown by the multiplicity of versions and editions which have survived Moreover, it was not without influence upon some of the writers whose work is contained in the Old Testament (*e.g.,* Daniel and some of the Psalms), Jewish pseudepigraphists (*e g,* the authors of the Book of Jubilees, the Testament of Job), some New Testament writers (*e g,* the Synoptists, especially in the description of the Resurrection and Ascension, St Paul, the author [s] of the Pastoral Epistles) and numerous post-apostolic Christian writers, many of whom, as did in particular Clement of Alexandria, regarded it as "Scripture." But in one respect it has achieved a distinction shared by no other Book of the Apocrypha, and by at most only one book (Jonah) of the Old Testament: it has made a remarkable appeal to the exponents of Christian Art, and its hero and his dog and certain dramatic incidents in his history became, in the Middle Ages, a favourite theme of the workers in ecclesiastic glass and mural decorations.

Date of the Work.—Hitzig's relegation of the date of writing to a time subsequent to the catastrophe of A D 70, Graetz's conviction that it belongs to the reign of Hadrian, Rosenthal's that it is a product of the School of Rabbi Akiba, and even W. R. Smith's attempt to connect it with the Maccabean revolt, are no longer favoured. Equally impossible is a date as early as 350 B.C., which was once favoured by writers influenced by Ewald. A date about 250 B C. seems to present least difficulties.

The author wrote to inculcate respect for the dead, consanguineous marriages, and practical virtues such as almsgiving. He found the ultimate sanction for these ideals in the Old Testament, but when he set out to inculcate them in his tale he drew on earlier, and even contemporary pagan models. The Egyptian *Tractate of Khons* supplied him with the idea of a maiden possessed by a demon whom the god expelled It is also clear that the widely diffused "Fable of the Grateful Dead"—a dead man rewarding the burier of his corpse—was much in his mind when he set out to write his book, but in this case it may have been less a matter of consulting a literary model than of reproducing the general ideas of a class of fables known to him from boyhood. Similarly there is no reason to posit any literary source, as J. H Moulton formerly did, to account for the alleged *Median* and more specifically Magian elements in the book—*e.g.,* the dog, the demon Asmodeus (Aēšma daēva), the *seven* angels, the saving heavenly visitor (Raphael). These are mostly not characteristics of the *later* Zoroastrian system, but belong equally to its earliest phases, and in great part even to pre-Zoroastrian Magianism, which, by 250 B C., would be known wherever Persian traders and soldiers were to be found

If, as is suggested, the author was an Egyptian Jew of 250 B C., he may have written in Aramaic or in Greek. Numerous attempts, based on the theory of mistranslations in the extant Greek texts from an Aramaic original have been put forward, but on the whole the hypothesis that he was a Jew who "thought in" Hebrew or Aramaic, while writing in the Greek of his period, suffices to explain the "Semitisms" which are observable in his Book Apart from the poem in ch. 13 there seems to be no reason for not regarding the book as a literary unity.

(1913) pp. 516–30; also *The Book of the Words of Tobit with an Introductory Essay by Ernest H. Short and Reproductions of Paintings by the Old Masters,* 1927

TOBOGGANING, the sport of sliding down snow-covered hills and artificial ice-shutes on the toboggan, a sled from 3ft to 8ft. long and 2ft. to 3ft. wide, formed of strips of wood from ¼in to ½in in width, fitted together and curved up at the front (Micmac Indian, *tobaakan,* sledge) The toboggan is not so well fitted for use on roads that are not steep or very smooth as is the sled provided with runners, but is generally used on open hills, or upon artificial courses (chutes), which are very popular in Canada. In Switzerland tobogganing on this type of sled is called lugeing, and the sleds are known as luges; it is a popular sport with visitors to the Engadine, where both the sitting and *ventre-à-terre* position are practised The run from the top of the Schatzalp at Davos is one of the best luge-runs in Switzerland.

On the big runs, of which the Cresta is the most famous, the steel skeleton type of toboggan is invariably used, and the runner is equipped with knee and arm pads and a felt-lined steel crash helmet to protect him in the event of accidents; specially constructed boots with steel spikes render steering and braking with the feet easy The Cresta is built with several turns banked up with solid ice (*See* also COASTING.)

The United States.—With slight variations, toboggans are constructed, in the United States, in the same manner and of the same materials as in other parts of the world. Toboggans are best fitted for the soft fluffy snow of dry-cold climates, their flat bottoms and curled up fronts riding the surfaces with ease. They are often used for transportation purposes where other conveyances are of no use Dogs, sometimes called huskies, haul toboggans on hunting and camping trips through the north woods In Alaska, teams of dogs of from 2 to 12 animals are frequently used to pull toboggans loaded with supplies and provisions. Toboggan racing between Alaskan cities is a popular sporting

event and very often the winner of a toboggan Derby will receive a cash prize of several thousand dollars.

TOBOLSK, a town in the Uralsk Area of the Russian S.F.S.R., in 59° 22′ N, 68° 5′ E., on the Irtysh river, below the confluence of the Tobol. Part of the town is low-lying and subject to floods, but the upper part is 200 ft above the river and is crowned by an old fortress built in the reign of Peter the Great by Swedish prisoners, in imitation of the Kremlin at Moscow. The river is usually frozen from Nov. 20 to May 14, and vessels from the Ob can reach the town in flood time; the S S Louise reached it from Hull in 1877. Twelve miles south-east are the ruins of the "fort of Kuchum" (Isker, Sibir) captured by Yermak in 1581. Tobolsk was founded by the Cossacks in 1587, and formerly had an active trade in fish and furs, but Omsk rapidly superseded it. The only industrial enterprise is a preserve factory using cranberries, rockcherry and honey. If the railway constructed in 1917 from Sverdlovsk to Saitkovo on the Tavda, is prolonged to Tobolsk, its trade may revive, and with it the former sawmilling and match industry. The district around is noted for koustar (peasant) industries, especially carpentering, the making of fishing nets, carving on mammoth ivory and the preparation of wool and skins. The Tobolsk province was the earliest to be colonized, and also received the largest number of political exiles.

TOBRUK (anc *Antipyrgos*), a fine natural harbour situated in Cyrenaica, Italian North Africa, on the N. coast of Africa at the intersection of 32° N Lat, with 24° E Long (Pop. 1,500) The harbour, which is small but deep, and sheltered by high ground, opens to the east. It is about 2½ m. long by ½ m. wide; the depth in the centre is over 40 ft and soundings of over 30 ft extend to within a very short distance of the shores. It is the only safe port easily accessible to large vessels for over 1,000 m, between Sfax in Tunisia and Alexandria. Tobruk has long been the outlet for the trade of the oases which extend from Jarabule to Siwah.

TOCCATA, in music, a composition of indefinite form but of brilliant, fantasia-like character, with a preponderance of running passages, calculated especially to display the execution of the performer. (It *toccare*, to touch) Among the earlier masters, Bach left some magnificent examples, developing the highest possibilities of the form (*see* article on that composer), while well-known modern examples are those of Schumann and Debussy.

TOC H, an interdenominational organization for Christian social service, founded as a memorial to British youth who perished in the World War At Hooge, in the first German liquid fire attack in July 1915, there fell a lad named Gilbert Talbot, lieutenant in the Rifle Brigade and son of the bishop of Winchester In the following December in the Flemish town of Poperinghe a soldiers' club named "Talbot House" was opened in his memory.

In charge of this house was a Church of England chaplain, the Rev. P. B. Clayton, M C, who created there a centre of rest and recreation unique in its kind In 1920 Clayton established in London a new Talbot house, using, as this name was already appropriated, the signallers method of pronouncing its initials, namely "Toc H" The plan was to establish in the salient of London a house where men of all kinds would congregate and many of them live, dedicating a reasonable proportion of their leisure time to the service of their fellow men and, by including in its membership all men of goodwill

In 1922 the movement had so extended, not only through houses or "Marks" as they are called but also in branches throughout the country that it became incorporated by royal charter, with H R H. the Prince of Wales as its patron. In 1928 it had extended through the English speaking world and beyond the confines of the British empire. Capturing the imagination of youth by its call to service and sacrifice, developed on a wide yet deep interdenominational Christian basis, drawing together men of all classes and types often mutually antagonistic, it has become one of the greatest powers for good, by service to man, fellowship of the most genuine kind and spiritual development and expression. Regular membership involves a probationary test and the work of its members and branches is reviewed annually. Each branch is entrusted with a Lamp of Maintenance, first lighted by the patron and relighted with simple ceremony at every meeting in remembrance of "the Elder Brethren" and in re-dedication to the task they left unfinished—building "a new Jerusalem." (R. C G)

TOCHI VALLEY or DAWAR, one of the chief routes into Afghanistan in the North-West Frontier Province of India. It leads from the Bannu through tribal country, and is inhabited by the Dawari (*q.v.*). The valley is divided into two parts, known as Upper and Lower Dawar, by a narrow pass called the Taghrai Tangi, some three m long Between Dawar and British territory is the low range of uninhabited hills, which skirt the Bannu district. It was by this route that Mahmud of Ghazni effected several of his raids into India and the remains of a road flanking the valley and of defensive positions are still to be traced. After the Waziristan Expedition of 1894 the Tochi was garrisoned by British troops; but when Lord Curzon reorganized the frontier in 1901, the British troops were withdrawn, and their place supplied by tribal militia The chief posts are Saidgi, Idak, Miranshah, Datta Khel and Sheranni. The valley was the scene of action for the Tochi or Dawari Expedition under Brigadier-General Keyes in 1872, and the Tochi Expedition under General Corrie Bird in 1897. Since the disturbances following the World War a motor road has been made up the valley.

TOCQUEVILLE, ALEXIS HENRI CHARLES MAURICE CLEREL, COMTE DE (1805–1859), was born at Verneuil on July 29, 1805 Alexis de Tocqueville became an assistant magistrate in 1830 A year later he obtained from the French Government a mission to examine prisons and penitentiaries in America On his return he wrote *De la Démocratie en Amérique* (1835, 3rd ed., 1868). It was at once caught up by influential members of the Liberal party in England, which country Tocqueville soon after visited, and where he married an Englishwoman Returning to France, he was elected a member of the *Académie des sciences morales et politiques* (Jan 6, 1838) He sat in the chamber of deputies for several years both before and after the revolution of February, becoming in 1849 vice-president of the assembly, and for a few months minister of foreign affairs. He was a warm supporter of the Roman expedition, but an equally warm opponent of Louis Napoleon; he was arrested at the *coup d'état,* and retired from public life. Twenty years after his first, he produced another book, *De l'ancien régime,* which almost, if not quite, equalled its success. His health was never very strong, and in 1858 he broke a blood-vessel. He was ordered to the south, and died at Cannes on April 16, 1859. His complete works, including much unpublished correspondence, were produced after his death in uniform shape by H G de Beaumont (*Oeuvres complètes de Tocqueville*, 9 vols, 1860–1865)

During the last twenty years of his life, and for perhaps half that time after his death, Tocqueville had an increasing European fame He was the first and has remained the chief writer to put the orthodox liberal ideas which governed European politics during the first half or two-thirds of the 19th century into an orderly and attractive shape He wrote the first reasoned political account of democratic government in America. If not an entirely impartial writer, he was neither a devotee nor an opponent of democracy.

See Heinrich Jacques, *Alexis de Tocqueville; ein Lebens- und Geistesbild* (Vienna, 1876), James Bryce, *The Predictions of Tocqueville* (Baltimore, 1887), Count de Puymaigre, *Les Souvenirs d'Alexis de Tocqueville* (1893, Eng trans 1896) and *Correspondance entre Alexis de Tocqueville et Arthur de Gobineau* (1908).

TODA, a small pastoral tribe found on the Nilgiri hills in south India. Like the Nairs (*q v*), they form an islet of tall, well-bearded, straight-nosed men with rich brown complexions in the midst of the darker Dravidian peoples. The women are lighter in colour, and wear a single garment arranged as a mantle The men wear a similar one as a plaid. They practise adelphogamy, and have only three women to five men, but female infanticide probably only survives among the priesthood

See W. H. R. Rivers, *The Todas* (1906).

TODHUNTER, ISAAC (1820–1884), English mathematician, son of George Todhunter, a Nonconformist minister, was born at Rye on Nov. 23, 1820, and died at Cambridge on March 1,

1884. He was educated at University college, London, and at St. John's college, Cambridge. He became a fellow of his college and college lecturer and private tutor. Todhunter held many academic honours, and was a member of council of the Royal society. He became an assistant master at a school at Peckham, attending at the same time evening classes at the University college, London. In 1842 he obtained a mathematical scholarship and graduated as B A. at London university. In 1844 he entered St. John's college, Cambridge, where he was senior wrangler in 1848, and gained the first Smith's prize and the Burney prize; and in 1849 he was elected to a fellowship, and began his life of college lecturer and private tutor. In 1862 he was made a fellow of the Royal Society, and in 1865 a member of the Mathematical Society of London. In 1871 he gained the Adams prize and was elected to the council of the Royal Society. He died at Cambridge on the 1st of March 1884

WORKS—*Treatise on the Differential Calculus and the Elements of the Integral Calculus* (1852, 6th ed, 1873); *Treatise on Analytical Statics* (1853, 4th ed, 1874); *Treatise on the Integral Calculus* (1857, 4th ed, 1874); *Treatise on Algebra* (1858, 6th ed, 1871), *Treatise on Plane Coordinate Geometry* (1858, 3rd ed, 1861), *Plane Trigonometry* (1859, 4th ed, 1869); *Spherical Trigonometry* (1859), *History of the Calculus of Variations* (1861), *Theory of Equations* (1861, 2nd ed 1875); *Examples of Analytical Geometry of Three Dimensions* (1858, 3rd ed, 1873), *Mechanics* (1867), *History of the Mathematical Theory of Probability from the Time of Pascal to that of Lagrange* (1865); *Researches in the Calculus of Variations* (1871); *History of the Mathematical Theories of Attraction and Figure of the Earth from Newton to Laplace* (1873); *Elementary Treatise on Laplace's, Lamé's and Bessel's Functions* (1875), *Natural Philosophy for Beginners* (1877) An unfinished work, *The History of the Theory of Elasticity*, was edited and published posthumously in 1886 by Karl Pearson

TODI (anc *Tuder*), a town and episcopal see of the province of Perugia, Italy, 26 m S of Perugia by rail, on a steep hill above the east bank of the Tiber, 1,348 ft above sea-level, and 866 ft. above the river Pop (1921), 5,776 (town), 18,245 (commune) Some portions of the ancient town walls—of two enceintes, an inner and an outer, the former attributed to the original Umbrian inhabitants, the latter to the Romans—are preserved, while the mediaeval walls are still more extensive, and also remains of baths, amphitheatre, theatre, and a substruction wall of massive masonry, with four niches Here was found the bronze statue of Mars, now in the Vatican; some fine bronze objects of the 5th cent B C have been found in tombs. Beneath the cathedral square, at the highest point of the town, is a large Roman reservoir. The Romanesque cathedral has a simple façade (partly of the 11th, partly of the 14th century), with a fine portal and rose window In the same square are the massive Romanesque Gothic structures, Palazzo dei Priori (1213), the Palazzo del Capitano del Popolo (*c.* 1290) and the Palazzo del Podesta (1293–1337). The Gothic church of S Fortunato, with its nave and aisles of the same height, has a splendid portal

Just outside the town on the west is the church of S Maria della Consolazione, one of the finest buildings of the Renaissance, and often wrongly attributed to Bramante Contemporary documents prove that the interior was begun in 1508 by Cola di Matteuccio da Caprarola, and the exterior completed in 1516–1524 by Ambrogio da Milano and Francesco di Vito Lombardo; the slender dome was not added till 1607

See Pirro Priore Alvi, *Todi* (1910); G Bellucci, *La regione di Todi prima della storia*, Perugia, 1915; Bendinelli in *Monumenti dei Lincei*, xxiii, 609–684; xxiv, 841–914.

TODLEBEN (or **TOTLEBEN**), **FRANZ EDUARD IVANOVICH,** COUNT (1818–1884), Russian engineer general, was born at Mittau in Courland, on May 20, 1818 He entered the school of engineers at St Petersburg, and passed into the army in 1836. In 1848 and the two following years he was employed, as captain of engineers, in the campaigns against Schamyl in the Caucasus. On the outbreak of war between Russia and Turkey in 1853, he served in the siege of Silistria, and after the siege was raised was transferred to the Crimea (*see* CRIMEAN WAR) Sevastopol, while strongly fortified toward the sea, was almost unprotected on the land side. Todleben, though still a junior field officer, became the animating genius of the defence By his advice the fleet was sunk, in order to blockade the mouth of the harbour, and the deficiency of fortifications on the land side was made good before the allies could take advantage of it. The construction of earthworks and redoubts was carried on with extreme rapidity, and to these was transferred, in great part, the artillery that had belonged to the fleet.

It was in the ceaseless improvisation of defensive works and offensive counterworks to meet every changing phase of the enemy's attack that Todleben's peculiar power and originality showed itself He never commanded a large army in the open field, nor was he the creator of a great permanent system of defence like Vauban. But he may justly be called the originator of the idea that a fortress is to be considered, not as a walled town but as an entrenched position, intimately connected with the offensive and defensive capacities of an army and as susceptible of alteration as the formation of troops in battle or manoeuvre Until June 20, 1855 he conducted the operations of defence at Sevastopol in person; he was then incapacitated by a wound

In 1860 Todleben was appointed assistant to the grand-duke Nicholas, and he became subsequently chief of the department of engineers with the full rank of general He was given no command when war with Turkey began in 1877 It was not until after the early reverses before Plevna (*q v.*) that the soldier of Sevastopol was called to the front Todleben saw that it would be necessary to draw works round Osman Pasha, and cut him off from communication with the other Turkish commanders In due time Plevna fell Todleben then undertook the siege of the Bulgarian fortresses After the conclusion of preliminaries of peace, he was placed in command of the whole Russian army When the war was over he became governor of Odessa and hereditary count But his health was broken For some time after 1880 he held the post of governor of Vilna He died at Bad Soden near Frankfort-on-Main, on July 1, 1884

His great work on the defence of Sevastopol appeared in Russian, French and German (5 vols, 1864–72) Besides this, he wrote a letter to General Brialmont on the operations around Plevna, this was printed in the Russian engineer journal, and in German in the *Archiv fur preussische Artillerie-offiziere* (1878)

See Brialmont, *Le Général comte Todleben* (Brussels, 1884), *Life* by Schild r (in Russian, St Petersburg, 1885–87), Krahmer, *General-Adjutant Graf Todleben* (Berlin, 1888)

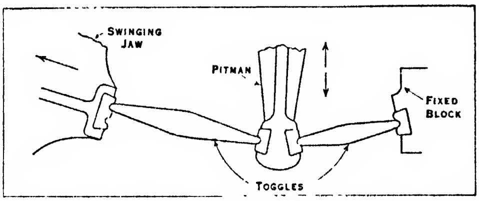
TODMORDEN, a municipal borough and market town in the West Riding of Yorkshire, England, 19 m N.N E of Manchester, on the L M S railway It lies in both the Sowerby parliamentary division of the West Riding and in the Middleton division of Lancashire Pop (1921) 23,892 It is situated on both sides of the river Calder, at an altitude of about 500 ft. and is surrounded by high moorland It is a railway junction for trans-Pennine routes from Manchester, Preston and Burnley to the industrial West Riding, and the Calder and Rochdale canal connects it by water with Rochdale and with towns lower down the Calder valley. The staple industry is the spinning and weaving of cotton and there are also foundries and machine-works. The municipal borough was incorporated in 1896.

TODY, a bird (*Todus viridis*) inhabiting Jamaica, with allied species in Cuba, Haiti and Porto Rico. A stolid bird, the tody is brightly coloured in grass-green, with a crimson gorget. It feeds on insects and, like its allies the king-fishers, constructs burrows in which to lay its white eggs.

TOGGENBURG, THE, an ancient county in the upper valley of the river Thur (Switzerland). On the death of the last count of Toggenburg (1436) Zürich and Schwyz, in the first intercantonal war, disputed its possession Purchased by the abbot of St. Gall in 1468, it was an area of constant strife between the abbots and the inhabitants, many among whom embraced Protestantism The Toggenburg war between the Roman Catholic cantons and Protestant supporters of the Toggenburgers resulted in a Catholic defeat (1712) and in the restoration of the ancient liberties. To-day it is a pleasant, highly prosperous part of the canton of St. Gall, inhabited by approximately equal numbers of Protestants and Catholics. Its exact limits are differently interpreted, but the entire upper valley of the Thur above the right-angled bend, near Wil, to the source near Wildhaus, is about 30 m long, and runs mainly south-east to north-west, be-

tween steep fir-clad slopes. Near the valley head are the Churfirsten range (Hinterruck, 7,575 ft.) southwards and the bold peaks of the Säntes (8,215 ft) northwards. The valley is well populated and has good through communications; a 20 m. railway runs from Wil, on the Winterthur-St Gall main line, to Nesslau, and public omnibuses make use of the excellent roads beyond, crossing the watershed near Wildhaus for Gams in the Rhine valley. The Toggenburg as a holiday area is still mainly confined to the Swiss themselves. The pastures throughout are unusually rich, but the predominant pastoral occupation of the upper half is replaced by manufactures, chiefly muslins, in the lower half. The old market centre of the valley was Lichtensteig, now surpassed in point of size and importance by several well built towns and villages, of which Wattwil (pop 6,100), near the entrance of the Ricken tunnel, is the largest.

TOGGLE-LEVER, a combination of three levers, one being at right-angles to the other two, and arranged so as to



A KNUCKLE FORM OF LEVER ACTION, TWO BEING STRAIGHTENED OUT BY A LATERALLY MOVING ONE

push against their closely-set ends One of the latter is pivoted at a fixed position, while its companion has endlong freedom Great power is obtained by the action of the lateral lever forcing the other two into a straight line One practical application is seen in the diagram, where the lateral lever is a rod, or pitman, given a short up and down motion from an eccentric on a shaft fitted with a heavy flywheel As the pitman rises, it forces the toggles (which are wide pieces in this case) into line, and exerts great pressure against the pivoted jaw The latter crushes rock or stone against a fixed jaw face Another valued application of toggles is in power presses for drawing hollow sheet-metal articles, such as bowls, pans, etc, from the flat sheet This operation necessitates holding the sheet firmly around the die during the drawing The toggle mechanism does this and transfers the great stress direct to the frame of the machine, instead of throwing it on the crankshaft

TOGO, HEIHACHIRO, Count (1847-), Japanese admiral, was born in Kagoshima, the son of a petty retainer. He joined the navy in 1863 and his first engagement was the "Kwaiten" five years later He studied naval science and navigation in England from 1871 to 1878, and first became a prominent figure when, in 1894, as captain of the cruiser "Naniwa," he sunk the Chinese troopship "Kowshing" *en route* for Korea, thus precipitating war with China When the Russo-Japanese conflict broke out in 1904, he was appointed to the command-in-chief of the Japanese fleet, and under his direction various brilliant operations took place, culminating in the battle of the Sea of Japan when the Russian fleet was annihilated. For these services he received (1907) the title of count. In 1906 he was made a member of the British Order of Merit (*See* Russo-Japanese War)

TOGOLAND, a country of West Africa (the French and German form is Togo). The maritime zone forms part of what was distinguished as the Slave Coast; it lies between the Gold Coast and Dahomey and extends from 1° 14′ E. to 1° 38′ E. Annexed to Germany in 1884, it was given a hinterland of nearly 35,000 sq. miles. Since 1919 it has been divided into British and French spheres (see *infra*).

Physical Features.—The coast is low and sandy and is formed by the detritus deposited by the sea current called Calema It is perfectly straight, without harbours, and approached only through a dangerous bar This coast strip, but 32 m. long, is nowhere more than 2 m broad It masks a series of lagoons, of which the largest, occupying a central position, is called the Togo, Avon or Haho lagoon Behind the lagoons an undulating plain stretches some 50 miles The Sio and Haho, the two largest rivers of the coast region, both flow into the Togo lagoon These rivers rise on the eastern versant of a chain of mountains which traverse the country in a south-westerly to a north-easterly direction. It has no general name but in the south is called Agome It is most elevated in its southern portion, Mt Dabo having a height of 3,133 ft. and Mt Atilakuse 3,248 feet Its general elevation is between 2,000 and 2,500 ft ; on the north-west side of the range the country is table-land, some 600 to 1,000 ft high Baumann Spitze (3,215 ft) is an isolated peak in 6° 50′ N , 0° 46′ E , east of the main range South and east of the range the country, apart from that watered by the coast streams, drains to the Mono river, which, in its lower course, forms the Togoland-Dahomey frontier. The greater part of the country lies west and north of the chain and belongs to the basin of the Volta The chief river traversing it (north to south) is the Oti, a tributary of the Volta

The climate on the coast is hot, humid and unhealthy. There are two wet seasons, the first lasting from March till June, the second from September to November A marked feature of the climate is the prolonged period, December to April, in which the dry wind called *harmattan* prevails. The rainfall is thought to average 55 in a year in the southern districts On the tableland seasons of drought are not uncommon.

Coconut palms, introduced by the Portuguese, grow along the coast and for 80 m or so inland The lagoons are surrounded by dense belts of reeds, and the coast-land is covered with low, dense bush There are forests of oil palms, rubber trees and vines, and timber and dyewood trees. There are rain-forests on the mountains and along the river valleys On the hills the baobab and hyphaene palm are characteristic; on the plateau are stretches of open savanna and park-like country with clumps of silk cotton and shea-butter trees The fauna resembles that of other parts of West Africa; it is poor on the coast

Inhabitants.—In the south-west the inhabitants are negroes of the Twi-speaking clans, while on the coast and in the south-east they are members of the Ewe (Dahomey) tribes Among the coast people there is a distinct infusion of Portuguese blood, and in all the ports are descendants of Brazilian negroes who returned to Africa during the 19th century The northern tribes are distinct from the coast tribes, are of finer physique, and until recently went almost naked Among these tribes the Mamprusi and Dagomba, the Kotokoli and Bassari may be noted Though the Togoland natives number fewer than one million over 40 different languages are spoken As is common in West Africa the people are divided into a large number of independent tribes, each under its own head chief, who is, however, subject to the authority of a council of sub-chiefs and leading officials The use of poisoned arrows by the northern tribes still prevailed in 1928. In the coast lands the inhabitants are traders and agriculturists, in the interior they are largely pastoralists. The people are mostly pagans, but some thousands have embraced Christianity or Islam

There are a number of ancient towns on the coast and lagoons Togo is on the south-eastern shores of the Togo lagoon On the narrow spit of land between the lagoons and the sea are Bagida and Porto Seguro—the last named one of the oldest towns on the Slave Coast and the port of Togo town—and, close to the eastern frontier, Little Popo, called by the Germans Anecho On the Volta, a short distance above the Oti confluence, are the adjacent towns of Kete-Krachi; on an affluent of the Mono in 7° N is Sagada In the north are Yendi and Sansane Mangu, both on trade routes between Ashanti and the Niger countries Lome, the chief port, is at the eastern end of the coast

Economic Development Under the Germans.—In the 30 years the country was under German rule attention was paid chiefly to agriculture, trade and communications. A jetty was built at Lome and from it two railways started; one—opened in 1907—went north-north-west to Palime (72 m), the other—opened in 1911—due north to Atakpame (105 miles). Along the coast a railway connected Lome with Anecho and several good

roads had been built. Germans started plantations of coffee, cocoa, kola-nuts, rubber and cotton, but the most valuable trade was in palm oil and kernels There was also a trade in maize, ground nuts and shea-butter. Several inland tribes reared cattle and sheep, and on the tableland horses and donkeys. Strict labour regulations were enforced on the natives Direct steamship communication was maintained with Hamburg and Bremen, and most of the trade was with Germany The value of exports rose from £153,000 in 1900 to £498,000 in 1912. In the same period imports increased from £176,000 to £571,000 In 1912 the chief exports were palm oil and kernels (£240,000), rubber (£48,000), live cattle (£30,000), cotton (£26,000) and maize (£12,000) In 1913, the last complete year of German rule, the total exports were valued at £457,000, the imports at £531,000 The European population (1912) was 368, of whom 327 were Germans.

The British Sphere.—The British sphere adjoins the Gold Coast It has an area of 13,040 sq m. and a pop. (1921 census) of 187,959; of these 9,652 were Christians and 5,678 Mohammedans. European residents (1927) numbered under 50. The sphere is divided into two sections, the northern being administered as if it formed part of the Northern Territories of the Gold Coast, the southern as if it formed part of the Gold Coast Colony. The southern section is known as the Ho district and has some 80,000 inhabitants, who are more advanced in civilization than their northern neighbours. The chief towns are Ho and Kpando. In this district large areas are given over to cocoa, and smaller areas to cotton. There is also an oil palm belt The northern section is divided into districts, of which Kete-Krachi—in which there are cotton plantations—adjoins the Ho district. This northern district contains the towns of Kete-Krachi (pop about 9,000) and Yendi (4,500). Trade in the north is chiefly in cattle and foodstuffs. The exports of the British sphere as a whole are mainly cocoa, cotton and palm kernels and palm oil; the chief imports are cotton piece goods, clothing, salt, tobacco and kerosene The division of Togoland left the whole railway system in the French sphere and the railway from Palime to Lome, which runs close to the border of the British sphere and is near to the chief cocoa farms, takes a large share of the trade The administration has, however, built good roads in the British sphere and a motor ferry over the Volta at Senchi connects the southern British section with the road system of the Gold Coast colony Separate statistics of the trade between the British sphere and the Gold Coast are not kept; the following figures relate to the trade crossing the frontier of the French sphere:—Year ending March 31, 1924: Exports £115,230 (cocoa £99,585); imports £24,400. Year 1926: exports £148,000 (cocoa £135,200); imports £26,000. In taking over the administration the Gold Coast authorities determined that the British sphere should have the same high standard in regard to public health, public works and education as the Gold Coast had. Consequently, expenditure for several years greatly exceeded revenue.

French Sphere.—The French sphere, which adjoins Dahomey on the east, has an area of 21,893 sq. miles In 1927 the pop was 742,808 natives, 331 Europeans and 49 Syrians. The sphere is administered as a separate entity, the chief official being styled commissioner. He is aided by an Economic and Financial Council (created in 1924), consisting of officials, merchants and nine native representatives. The native members are chosen by popularly elected councils and notables established in each district into which the sphere is divided.

The products and trade are similar to those in the British sphere, cocoa and cotton being of growing importance. There is also a trade in copra, an industry in the hands of the coast natives. Lome (pop. about 6,000) is the capital and centre of the external trade The chief imports, cotton piece goods, come almost entirely from Great Britain Exports were valued at 17,000,000 frs in 1922, and at 79,000,000 in 1926; in the same period imports rose from 10,000,000 frs. to 99,000,000 frs. France supplies about 25% of the imports and takes half of the exports In fiscal matters the French authorities sought to build up a reserve from which to undertake public works, and revenue for several years exceeding expenditure, a sum equal to £250,000 had been accumulated by 1927, in which year the budget was balanced at 33,380,000 frs. (£2,670,000) A programme of public works was then put in hand.

HISTORY

Foundation of a German Colony.—When Dr. Gustav Nachtigal was sent by the German Government to west Africa in 1884 as imperial commissioner on an annexation errand, he had the fortune to find between the Gold Coast (British) and Dahomey (French) a small stretch of the Guinea coast, sovereignty over which was not claimed by any European Power. The king of Togo—the ruler of this little patch—was induced to sign a treaty (July 5, 1884) placing his country under German suzerainty. Thus Togoland was founded, and by arrangement made with Great Britain and France a coast line of 32m was obtained Before the coming of the Germans as rulers, Portuguese, British, French and German firms had trading agencies along the lagoons behind the coast. In earlier days trade was chiefly in slaves (exported) and gin (imported); in later days the products of the oil palm had taken the place of slaves. The natives were in general dependent upon the rulers of Dahomey or Porto Novo; but the towns of Little Popo and Togo were capitals of small States which claimed freedom With the development of French interests in Dahomey there was the prospect of these minute kingdoms being absorbed by France In Togo town, however, Bremen merchants were influential and this fact helped Nachtigal to conclude his treaty Germany at once advanced claims to a large hinterland, and this caused a great deal of negotiation with Great Britain and France. It was not until 1899 that the inland frontiers of Togoland were fixed, Germany securing an area somewhat larger than Ireland Many of the tribes expressed preference for French or British rule respectively but the Germans had no great difficulty in making good their authority. The people were fairly good agriculturists and the Germans steadily developed the resources of the country; they created a port—Lome—and built railways After 20 years' work Togoland was self-supporting; it was the only German colony in Africa to attain that position

The World War.—In the first month of the World War (Aug 1914) Togoland was conquered by a British force from the Gold Coast under Capt. (temp. Lt -col) F. C Bryant, aided by detachments sent by the French from Dahomey Before surrendering, the Germans blew up the powerful wireless station at Atakpame, which had been completed a little earlier in the year and which communicated directly with Berlin Thereafter the western part, including Lome, was administered by the British and the eastern part by the French. Germany renounced her sovereignty by the Treaty of Versailles and the Supreme Council gave the mandate for its government to Great Britain and France The first division, made in an Anglo-French agreement of July 10, 1919, gave dissatisfaction to French colonial circles, as it left Lome to Great Britain, and by a convention of Sept 30, 1920, in exchange for an enlarged British area in the interior, Lome and the whole seaboard went to France. Both spheres are governed under mandates approved by the Council of the League of Nations on July 20, 1922, and, in each, citizens of the United States have obtained the right to equal treatment with the nationals of the members of the League. In both spheres the administration was carried on with the co-operation of the natives and without friction, there being a great development in trade.

See H. Klose, *Togo unter deutscher Flagge* (1899), a comprehensive survey, with bibliography; *Togoland,* a British Foreign Office handbook (1920); and the annual reports published by the British and French Governments on their respective spheres. (F. R. C.)

TOKAJ, a town in Hungary, at the confluence of the Bodrog and the Tisza and at the foot of the Hegyalja mountains which slope from a height of 2,700 ft. to a hilly plateau of 1,500 ft. near Tokaj. Here is the vineyard region of nearly 150 sq m. on a volcanic soil. The vines are believed to have been introduced by Italian colonists in the 13th century. From their grapes is produced the famous wine Tokay, the trade in which is the principal occupation. Pop. (1920), 5,073.

TOKAT, the chief town of a vilayet in Asia Minor. It is situated in the Sivas-Samsun *chaussée,* altitude 2,280 ft, at the mouth of a rocky glen which opens out to the broad valley of the

Tozanli Su, a tributary of the Yeshil Irmak. It rose to importance under the Seljuks. Pop. (1927), 77,579. The industries are the manufacture of copper utensils and yellow leather, and the stamping of colours on white Manchester cotton.

TOKELAU ISLANDS: *see* PACIFIC ISLANDS.

TOKUGAWA, YOSHINOBU, PRINCE (1837–1913), Japanese statesman, was born on Sept. 29, 1837 at Tokyo. He was the last of the Tokugawa Government, succeeding as shogun the 14th shogun, Iemochi, in 1866. Realizing after a year's time that the proper government of the country was impossible on the lines of feudalism, which was a bar to all progress and a source of continual internal strife, the shogun handed his resignation to the emperor on Oct. 14, 1867. This act of sacrifice was the prelude to the enlightened Meiji era, which dates from the beginning of 1868. Tokugawa, having renounced his shogunate rights, went into a strict retirement from which he never emerged. He even renounced the succession to his title for his direct heir in favour of a collateral branch of the family, the first to inherit the title being Prince Iyesato Tokugawa, for many years president of the house of peers The Emperor Meiji accepted the renunciation, but he conferred on him another title of prince to be bequeathed to his son He died on Nov 21, 1913 at Tokyo.

TOKUTOMI, IICHIRO (1863–), Japanese journalist and author, was born at Kumamoto in Jan. 1863 and educated at the Doshisha, Kyoto. In 1887 he issued a monthly magazine, *The Friend of the Nation*, and in 1890 started in Tokyo the daily *Kokumin Shimbun* (Nation), of which he was proprietor and editor. He also began to issue in the same year *The Far East,* an English monthly. Tokutomi, who was appointed a crown member of the House of Peers in 1911, published many important political and historical works including *The Future Japan* (1886) and *History of Modern Japan,* not yet complete. In 1924 the Imperial Japanese Academy awarded him the emperor's medal in recognition of the merit of his works on Japanese history.

TŌKYŌ, the capital of the empire of Japan, situated in 35° 41′ N. and 139° 45′ E, at the head of the bay of the same name on the south-east coast of the main island. In old times the city was called Yedo The city stands on the banks of the river Sumida, which, although wide, is unnavigable by vessels of large tonnage owing to its shallowness Yokohama, with which Tōkyō is connected by 18 m of railway, is practically the port of the capital The trains of the Tokai-do line, starting from the Shimbashi station, run westwards to Kobe, thence to Shimonoseki, at the western end of the main island, a distance of 700 m. The Uyeno station is the starting-point for trains to Aomori, a town 460 m. away, at the northern extremity of the island. The area of Tōkyō is about 100 sq m Topographically it may be divided into two parts, upland and lowland (Yamanote and Shitamachi) There are hills varying in height from 50 to 130 ft. in the upland district; that is to say, the outskirts of the city from north to west. Lowland Tōkyō, that part of the city covering the flats on both sides of the river Sumida, is intersected by a system of canals. The Nihon-bashi (Bridge of Japan), in the district of the same name, is famous, from this point all distances in Japan are measured. The largest bridges are those named Azuma, Umaya, Ryogoku, Shin-o and Eitai over the Sumida.

The streets are still, in some places, narrow and irregular; electric tramcars run throughout the city carrying passengers at a uniform rate of 5 sen, which means that it is possible to travel some 10 m. for about one penny. The jinrikisha, drawn by one man or sometimes two men, which were formerly the chief means of passenger conveyance, have notably decreased in number since the introduction of the trams Tōkyō suffers frequently from earthquakes. The numerous residences of the daimyos were the chief characteristics of the old town, especially in the Kojimachi-ku. Many of these have been demolished and government offices erected on their sites; others have given place to new streets and houses. Nearly in the centre of Kojimachi-ku, on an eminence, surrounded by moats, stood the castle of Yedo, formerly the residence of the shōguns, which was burnt down in 1873. The imperial palace was subsequently erected on this site. The palace is half European and half Japanese in its style of architecture. The Nijū-bashi is the main entrance. Hibiya Park is modelled on the European style, while retaining the special features of the Japanese gardeners' art. The largest and most beautiful are those in Shiba and Ueno, formerly the mausolea of the shōguns In Ueno, too, are the Imperial Museum, the Imperial Library and the Zoological Gardens. The famous temple of Kwannon, the goddess of mercy, is in Asakusa Park, in which a permanent fair is held.

Administration.—For administrative purposes Tōkyō is divided into fifteen districts or *Ku,* of which Kojmachi, Hongo, Koishikawa, Ushigome, Yotsuya, Akasaka, Azabu and Shiba are situated in the upland portion, while Kanda, Kyobashi, Nihonbashi, Shitaya, Asakusa, Honjo and Fukagawa are in the lowland. Suburban Tōkyō is divided into eight districts or *Gun,* which, with the city proper, collectively form the Tōkyō-Fu (prefecture), under the general control of one governor called Fu-Chiji. Questions affecting the interests of the whole Fu come before the *Fukwai,* or prefectural assembly, made up of representatives from both *Ku* and *Gun,* and a prefectural council, of which the governor is president; while matters concerning the city alone are discussed by a *Shi-kwai,* or municipal assembly, and administered by a municipal council, of which the Shicho or mayor is president. There is a regular water supply worked by the municipality Both police and fire brigade are under the command of a single *Keishisokan* (inspector-general). The telephone system is extensive, including long-distance wires to Yokohama, Osaka and other large towns There are many schools for advanced students devoted to the various branches of science, mechanics and art. The imperial university of Tōkyō, which consists of the colleges of law, medicine, literature, science, engineering and agriculture, is the principal institution of learning in the empire There are several daily newspapers as well as weekly and monthly publications of all kinds. In the lowland part of the city and in the suburbs there are many factories, their number having so much increased recently that Tōkyō may now be described as an industrial city

Population.—There are no reliable data as to the population of Yedo during the shōgunate Owing to the influx caused by the periodical visits of the daimyōs (feudal lords) with their numerous attendants, it probably exceeded $1\frac{1}{2}$ million during the period 1800–50 In 1925 the population was 1,995,567.

History.—No mention is made of Yedo or Tōkyō in Japanese history before the end of the 12th century It appears to have assumed no importance till about 1457, when Ota Dokwan, a general in the service of Uyesugi Sadamasa, governor of Kamakura, built a castle here About thirty years later the town fell into the hands of Hōjō of Odawara, and on his overthrow by Hideyoshi and Iyeyasu, the castle was granted to the latter, who was the founder of the shōgun house of Tokugawa In 1590 Iyeyasu made his formal entry into the castle of Yedo, the extent of which he greatly enlarged. From this date the real importance of Yedo began. The family of the Tokugawas furnished the shōguns of Japan for nearly three hundred years, and these resided during that period at Yedo At the restoration in 1868 the shōgunate was abolished, and the population of Yedo speedily decreased. A fresh vitality was imparted by the transfer of the court from Kyoto, and the town then received its present name Tōkyō (eastern capital). In Sept. 1923 a disastrous earthquake followed by extensive fires razed several districts of Tōkyō to the ground An area of 25 sq m was burnt and numerous bridges were destroyed Reconstruction of a purely temporary nature was rapid Shimbashi bridge was re-opened in 1925 but in the same year the new Parliament buildings were destroyed by fire.

University. (*See* UNIVERSITIES.)—By recent imperial ordinances and various other developments this has become the centre of progressive university education in Japan It has now faculties of law, medicine, engineering, agriculture and economics, in addition to those of science and letters, with no less than 255 members of the academic staffs. The Tōkyō astronomical observatory is directly attached to the university, which also takes a definite part in the compilation of national and geographical records. By Law 8 of March 27, 1922, the Government appropriation for the university was sanctioned as 2,984,805 yen

TOLAND, JOHN (christened JANUS JUNIUS) (1670–1722), English deist, was born on Nov. 30, 1670, near Londonderry, Ireland Brought up a Roman Catholic, in his sixteenth year he became a zealous Protestant. He studied at Glasgow, and then at Leiden under the famous scholar Friedrich Spanheim. He went in 1694 to Oxford where he began the book which made him famous—his *Christianity not Mysterious* (1696, anonymous; 2nd ed in the same year, with his name; 3rd ed, 1702, including an *Apology for Mr Toland*) It gave great offence, and several replies were immediately published. The author was prosecuted by the grand jury of Middlesex, and, when he attempted to settle in Dublin at the beginning of 1697, he was denounced from the pulpit and elsewhere His book having been condemned by the Irish parliament (Sept 9, 1697) and an order issued for his arrest, Toland fled to England The resemblance, both in title and in principles, of his book to Locke's *Reasonableness of Christianity,* led to a prompt disavowal by Locke of the supposed identity of opinions, and subsequently to the famous controversy between Stillingfleet and Locke Toland's next work of importance was his *Life of Milton* (1698), in which a reference to "the numerous supposititious pieces under the name of Christ and His apostles and other great persons," provoked the charge that he had called in question the genuineness of the New Testament writings. Toland replied in his *Amyntor, or a Defence of Milton's Life* (1699), he opened up the question of the history of the scriptural canon In 1701 Toland spent a few weeks at Hanover as secretary to the embassy of the earl of Macclesfield, and was received with favour by the electress Sophia in acknowledgment of his book *Anglia Libera,* a defence of the Hanoverian succession. On his return from the Continent he published *Vindicius Liberius* (1702), in which he described *Christianity not Mysterious* as a youthful indiscretion. The next year he visited Hanover and Berlin, and was again graciously received by the electress and her daughter Sophia Charlotte, queen of Prussia, the "Serena" of the *Letters* published on his return to England (1704) In two of these (*A Letter to a Gentleman in Holland,* and *Motion essential to Matter*), ostensibly an attack on Spinoza, he anticipated some of the speculations of modern materialism The *Account of the Courts of Prussia and Hanover* (1705) was used by Carlyle in his *Life of Frederick the Great* From 1707 to 1710 Toland lived in varying circumstances on the Continent In 1709 he published (at The Hague) *Adeisidaemon* and *Origines Judaicae.* The last of his theological works were *Nazarenus, or Jewish, Gentile and Mahometan Christianity* (1718) in which he maintained that the early Christians were Jewish Christians observing the Mosaic law and that their successors were the Nazarenes or Ebionites afterwards regarded as heretics by the Church

His last book, *Pantheisticon* (1720), gave great offence He died on March 11, 1722, in London, as he had lived, in great poverty, with his pen in his hand The term "free-thinker" was first applied to Toland, who indeed uses it himself

See Mosheim's *Vindiciae antiquae christianorum disciplinae* (1722), containing the most exhaustive account of Toland's life and writings; a *Life of Toland* (1722), by "one of his most intimate friends"; "Memoirs of the Life and Writings of Mr John Toland," by Des Maizeaux, prefixed to *The Miscellaneous Works of Mr John Toland* (London, 1747), and also G. Berthold, *John Toland und der Monismus der Gegenwart* (1876).

TOLEDO, a province of Spain, formed in 1833 from part of New Castile; bounded on the north by Ávila and Madrid, east by Cuenca, south by Ciudad Real and west by Cáceres. Pop. (1920), 442,933; area 5,919 sq. miles. The surface is mountainous. Towards the centre there are extensive tablelands, but the whole of the south and east is occupied by the Montes de Toledo, and the hills which separate the waters of the Tagus on the north from those of the Guadiana on the south. Toledo is well watered by the Tagus (*q v*) and its numerous affluents. Gold, silver, lead, iron, quicksilver, copper, tin and other minerals have been discovered, but the mining industry does not prosper and there is little export trade in agricultural products. The principal manufactures are silk and woollen cloth, earthenware, soap, oil, chocolates, wine, rough spirit (*aguardiente*), guitar strings and arms. There is also a small trade in charcoal and timber. The province is traversed by three lines of railway—that of Madrid–Seville–Cadiz in the east, Madrid–Toledo–Ciudad Real through the centre, and Madrid-Cáceres-Lisbon in the north.

TOLEDO, the capital of the Spanish province of Toledo and formerly of the whole kingdom, 47 m. by rail S.S.W. of Madrid, on the river Tagus, 2,400 ft above sea-level. Pop (1920) 25,251. Toledo is of immemorial antiquity; it was a stronghold of the Carpetani and may have been a Carthaginian trading-station. Livy (xxv. 7) mentions *Toletum* as *urbs parva, sed loco munita,* which was captured by the Romans in 193 B C. Under Roman rule it became a *colonia* and the capital of Carpetania. Its ecclesiastical importance is coeval with the introduction of Christianity into Spain; there were numerous church councils held here, notably in 396, 400 and 589, and here also was the chief battle ground in the long political and religious struggle which ended (589) in the triumph of Spanish Catholicism over Arianism. From the reign of Athanagild (534–547) until the Moorish conquest in 712, Toletum was generally regarded as the capital of Visigothic Spain. The Moorish chroniclers grow eloquent over the treasures captured by Musa and his army in 712 *Tolaitola,* as the city was then called, prospered under the Moors, first as a provincial capital in the caliphate of Cordova, governed by an emir (712–1035), afterwards as an independent state (1035–85) Its rulers protected the large Jewish colony, founded extensive silk and woollen industries, and made their city an important centre of Arab and Hebrew culture, one of the great names associated with it being that of Rabbi ben Ezra (1119–74) The Spanish and Jewish inhabitants adopted the language and many customs of their conquerors, becoming "Mozarabs," but retaining their own creeds In 1085 Alphonso VI of Leon and Castile captured Toledo, aided by the Cid, and in 1087 made it his capital, its commercial and political decline dates from 1560, when Philip II chose Madrid as his capital.

Toledo occupies a rugged promontory of granite, washed on all sides except the north by the Tagus, which here flows swiftly through a deep and precipitous gorge From a distance it has the aspect of a vast fortress, built of granite, defended by the river and by a double wall on the north, and dominated by the towers of its cathedral and alcázar The absence of traffic in its maze of dark and winding alleys creates a silence uncommon in so large a city The principal *plaza* is the arcaded Zocodover, described by Cervantes in the *Novelas ejemplares* The houses, tall,

THE PUENTE DA ALCANTARA ACROSS THE TAGUS RIVER, A MOORISH BRIDGE REBUILT IN THE 13TH AND 17TH CENTURIES

massive and sombre, are entered by huge iron-studded doors, and most of their windows open on a sheltered inner court (*patio*), the walls facing the street being often blank, though their monotony is sometimes relieved by carved stone-work

The Tagus is spanned by two fortified Moorish bridges, the Puente da Alcántara, on the north-east, which was rebuilt in the 13th and 17th centuries, and the Puente de San Martin, on the north-west, founded in 1212 and rebuilt in 1390. The Mudéjar Puerta del Sol is the finest of several ancient gateways, among which the Puerta Visagra (1550, restored 1575), and the Puerta

del Cambron (1102, restored 1576) are also interesting. The Puerta Visagra Antigua, a Moorish gateway of the 9th century, has been walled up, but its original form is preserved. The Alcázar, a huge square building with a tower at each corner and a fine arcaded *patio*, stands on the highest ground in Toledo, originally the site of a Roman fort, and now a military academy. Its fine façade designed by Juan de Herrera, a gateway by Alonso de Covarrubias and a staircase by Herrera and Francisco de Villalpando have been preserved. The Ayuntamiento, or City hall, is a 15th century building with 17th century alterations by Domenico Theotocopuli (el Greco).

The cathedral occupies the site of a Visigothic church St. Ferdinand founded the present cathedral in August 1227 The completion of the main fabric was delayed until 1493, while many of the chapels and other subordinate buildings were added even later; thus Renaissance and baroque features have been introduced into a design which was originally Gothic of the 13th century. The interior is 395 ft. long by 178 ft. broad, and is divided by 84 pillars into five naves, with central lantern and choir, and a complete series of side chapels. Most of the chapels date from the 15th and 16th centuries, and are very magnificent in detail The superb stained-glass windows, chiefly of Flemish work, belong to the same period and number 750 The choir-stalls, placed in alabaster recesses divided by columns of red jasper and white marble, are among the finest extant examples of late mediaeval and Renaissance wood-carving, though rivalled by the *retablo*, which rises behind the high altar to the roof The treasury, reliquaries and library still contain many priceless mss and works of art, including the silver monstrance executed by Enrique de Arfe in 1524, and paintings by Goya, El Greco, Titian and Rubens In the Mozarabic chapel mass is still performed daily according to the Mozarabic liturgy, which was also used in six of the parish churches until about 1850 (*See* MOZARAB)

Apart from the cathedral, many of the other churches are of great interest and beauty Several of them, notably Santo Tomé and San Vicente, contain masterpieces of El Greco (d 1614), many of whose pictures are collected in the Casa del Greco, founded by the Marqués de Vega-Inclán The Franciscan convent and church of San Juan de los Reyes (florid Gothic) were founded in 1476 by Ferdinand and Isabella. El Cristo de la Luz was originally a mosque, built in 922 and incorporating some pillars from an older Visigothic church. Santo Tomé, also a mosque, was reconstructed in the Gothic style during the 14th century. El Cristo de la Vega, formerly known as the Basilica de Santa Leocadia, occupies the site of a Visigothic church built in the 4th century to mark the burial-place of the saint. The Mudéjar Santa Maria la Blanca became successively a synagogue, in the 13th and 14th centuries, a church (1405), an asylum for women (1550), barracks (1791–98) and again a church.

Toledo's characteristic industry is the manufacture of swords, carried on by private firms and especially in the royal factory (1788), which, like the railway station, is about 1 m. from the city. Toledan blades have been famous for 2,000 years, the *culter toletanus* being mentioned in the *Cynegetica* of Grattius (Faliscus), during the 1st century B.C. The industry throve under the Moors and especially during the 16th century; it is now practised on a smaller scale, but the blades produced are still remarkable for flexibility and strength.

TOLEDO, a city of north-western Ohio, U.S.A, a port of entry and the county seat of Lucas county, on Maumee bay (the south-western tip of Lake Erie) at the mouth of the Maumee river. It is on Federal highways 20, 23, 24, 25 and 127, has a municipal airport of 225 ac.; and is served by the Ann Arbor, the Baltimore and Ohio, the Big Four, the Hocking Valley, the New York Central, the Nickel Plate, the Pennsylvania, the Pere Marquette, the Wabash, and the Wheeling and Lake Erie railways, several other steam lines for freight, nine electric railways and lake steamers. Pop. (1920) 243,164 (107 males to 100 females, and 82% native white); 1928 local estimate 313,200. The city has an area of 37 sq m., lying on both sides of the curving river, but chiefly on the west, with seven bridges connecting the east and west sides. It has tall hotels and business buildings; shaded residential streets; beautiful schools and public buildings, notably the well endowed Art museum, which houses a fine collection of Egyptian antiquities and glass and many canvasses of famous painters. There are 742 m of streets (360 m. paved), 482 m. of sewers, parks covering 2,004 ac., 21 m. of boulevards, 181 churches, 10 hospitals, 60 public and 35 parochial schools and a public library with 14 branches, containing 260,000 volumes The University of the City of Toledo (founded in 1872 as a private institution, and organized as a municipal university in 1884) has a campus of 160 ac and an annual enrolment of over 2,000. Toledo is the seat also of St John's university (Roman Catholic; 1898), several private secondary schools and a State hospital for the insane Private charitable organizations and welfare agencies are jointly financed through a community chest. The city operates under a mayor-council form of government, provided by the charter of 1914 There is an official city plan commission, and a comprehensive plan has been adopted.

The harbour has 35 m of shore line and a depth of 21 ft., accommodating the largest lake vessels. Its traffic in 1925 amounted to 16,304,042 tons, valued at $85,108,760, giving it third rank (after Duluth-Superior and Buffalo) among the ports of the Great Lakes. In 1927 it handled 16,340,070 tons of coal. Foreign commerce was represented in 1927 by imports valued at $2,456,795 (nearly all wheat) and exports of coal, corn, wheat and crude oil valued at $9,305,602 Domestic receipts amounted to $14,540,576 (largely iron ore, wheat, flax and oats), domestic shipments to $64,341,580, of which $7,868,450 represented automobiles and most of the remainder ($55,203,015) coal received by rail from the Ohio, Kentucky and West Virginia fields Toledo has a large wholesale trade, and is one of the leading markets of the country for clover seed, hay and grain, coffee and spices and winter vegetables Its manufacturing industries are important and highly diversified, with an aggregate output in 1927 valued at $437,499,441. The assessed valuation for 1925 was $584,523,250.

The site of Toledo lies within an immense tract acquired by the United States from several Indian tribes in 1795. A stockade fort (Ft. Industry) was built here about 1800. In 1817 two companies bought from the government most of the land now occupied by the city, and laid out two towns, Port Lawrence in 1817 and Vistula in 1832. They were united in 1833 under the name of Toledo, and in 1837 the town was chartered as a city The "Toledo War" was a dispute over the boundary line between Ohio and Michigan, both claiming a strip of rich agricultural land within which lay the site of Toledo, even then recognized as of great commercial importance. In 1818 the Ohio legislature accepted the "Harris line" (surveyed in 1817 in accordance with the State Constitution) and in 1835 the legislature, on the recommendation of Governor Lucas, passed an act providing for the organization of new townships in the territory thus added, and for the appointment of three commissioners to re-mark the northern State line On the appointment of the commissioners Governor Mason of Michigan ordered out a division of the territorial militia, which late in March 1835, took possession of Toledo. A division of Ohio militia marched to Perrysburg, 10 m south of Toledo Meanwhile President Jackson had sent Richard Rush of Philadelphia and Benjamin C Howard of Baltimore to Ohio as peace emissaries, and on their arrival at Toledo both forces disbanded. In June the Ohio legislature created Lucas county, mostly from the disputed territory, and made Toledo its judicial seat In June 1836, Congress decided the dispute in favour of Ohio, and in 1837 Michigan was admitted to the Union on condition of relinquishing all claim to the strip in question, receiving the upper peninsula by way of compensation. In 1840, three years after its incorporation, Toledo had a population of 1,222. Toledo's city administration became famous under the mayoralty of Samuel Milton ("Golden Rule") Jones (1846–1904), a manufacturer who was first elected by the Republican Party in 1897, and then re-elected on a non-partisan ticket in 1899, 1901 and 1903. He introduced business methods into the city's affairs,

and won his nickname through his honesty and sincerity in both business and politics. The independent movement started by him was carried on by Brand Whitlock (*q.v.*), mayor in 1906–13.

TOLEDO, COUNCILS OF. From the 5th to the 16th century about thirty synods, variously counted, were held at Toledo in Spain. As nearly one hundred early canons of Toledo found a place in the *Decretum Gratiani*, they exerted an important influence on the development of ecclesiastical law. The last council of Toledo was that of 1582 and 1583

(London, 1893); 151–169 These two summarize the chief canons Neher, in Wetzer and Welte's *Kirchenlexicon* (1855–57), vol xi. (2nd ed, Freiburg, 1899), gives a list of 29 synods

TOLENTINO (anc *Tolentinum Picenum*), a town of the Marches, Italy, in the province of Macerata, 11 m by rail W by S. of that town Pop (1921) 5,184 (town); 13,065 (commune). It is situated on the Chienti, 735 ft above sea-level, and was once a fortified town of great strength The church of S Nicholas of Tolentino has a fine portal by the Florentine Giovanni Rosso (1435) At Tolentino in 1815 a battle was fought in which the French under Murat were defeated by the Austrians

TOLERANCE. Manufacturing on the interchangeable system, which originated in the production of fire-arms, requires that pieces to fit together shall not exceed a certain maximum dimension or fall below a certain minimum dimension The margin of error between the maximum and minimum dimensions is termed the tolerance Exact sizes being a mechanical impossibility, the machines and tools which make the parts of an engine or machine are set and maintained to cut or grind such parts within certain limits The finer the limits the more costly the manufacturing becomes, hence the tolerances or margins must be calculated according to the class of work produced, *e g*, it is not necessary to work so closely on the parts of a large engine or machine as it is on a small mechanism or tool Grades of tolerance are therefore tabulated for various needs Tolerances usually range from the maximum amount of variation that the grade of work will permit to $\frac{1}{10,000}''$; thus the diameter of a shaft might have a tolerance of $\pm\frac{1}{1,000}''$ indicating that the shaft is permitted to be larger than standard by this amount or smaller by the same amount In the uni-lateral system the tolerance is expressed in only one direction. For example, $-\frac{1}{10,000}''$, and the diameter of the shaft might be basic size or $\frac{1}{10,000}''$ under basic size *Allowance*, a term distinct from tolerance, denotes the difference in the size of two mating pieces to make a particular quality of fit, either a tight force fit, an easy push fit or a running fit

TOLFA, a town of the province of Rome, Italy, 10 m E N E of Civitavecchia by road, 1,558 ft above sea-level Pop. (1921), 4,554. It is the chief place in the Tolfa Mountains, an extinct volcanic group between Civitavecchia and the Lake of Bracciano Vapours are emitted which deposit sulphur and alum, and alum mining is carried on The alum is treated both here and at Civitavecchia. Near Tolfa and Allumiere tombs of the early (pre-Benacci) Villanovan period, belonging to the 12th century B C. have been found.

See R. MacIver, *Villanovans and Early Etruscans* (Oxford, 1924).

TOLL, JOHAN KRISTOFFER, COUNT (1743–1817), Swedish statesman and soldier, was born at Mollerod in Scania, the son of one of Charles XII.'s warriors. He served in the Seven Years' War In the *coup d'état* of 1772 he ranged himself on the side of Sprengtporten (*q.v*), and was told to capture the southern fortress of Kristianstad By sheer bluff he won over the whole garrison on Aug 21, seven days later. Gustavus III.'s *coup d'état* at Stockholm completed the revolution. Toll was liberally rewarded. In 1783 he was placed at the head of the secret "commission of National Defence," which ruled Sweden during the king's absence broad In 1786 he had risen to the rank of major-general and was Gustavus's principal adjutant

After the death of Gustavus III., Toll was for a short time war minister and commander-in-chief in Scania, and was sent later as ambassador to Warsaw. Unjustly involved in the "Armfelt conspiracy," he was condemned to two years' imprisonment, but was reinstated in 1796 when Gustavus IV. attained his majority. At the riksdag of Norrköping, 1800, he was elected marshal of the diet and was an able leader of the royalist party. He carried on the negotiations with the Powers concerning Sweden's participation in the war against Napoleon. In the Pomeranian campaign of 1807 he helped to defend Stralsund, and on its surrender to Marshal Brune on Aug. 20, he persuaded the latter (Sept 7) to make a convention by which the Swedish army was allowed to return unmolested to Sweden, and was rewarded by his marshal's bâton In 1814 Bernadotte created Toll a count.

TOLLER, ERNST (1893–), German poet, was born in Samotschin on Dec. 1, 1893. On the outbreak of the World War he joined the army as a volunteer, but was invalided out. A Socialist and friend of Kurt Eisner, Toller took a very prominent part in the Munich revolution of 1919, for which he was sentenced in July 1919 to five years' imprisonment in a fortress. He achieved celebrity with his revolutionary dramas *Die Wandlung* (1920); *Masse-Mensch* (1921; Eng trans. 1923), *Die Maschinenstürmer* (1922; Eng. trans 1923) and *Hinkemann* (1924); and with two volumes of lyrics, written in prison, *Gedichte der Gefangenen* and *Das Schwalbenbuch* (1924, also Eng trans). His *Masse-Mensch* ("Masses and Man") was greeted in many circles as exemplifying a new theatrical technique and had much influence on the Russian theatre

See S. Grossmann, *Ernst Toller, Hochverrater und Dichter* (1919)

TOLSTOY, Count Leo (Lyov) Nikolayevich (1828–1910), Russian novelist and moral philosopher, was born on Aug 28, (Sept 9,) 1828, at his parents' country-place of Yasnaya Polyana, in the province of Tula. The Tolstoys are a family of Russian gentry dating back to the 16th century (*not* of German origin as is often affirmed, and as Tolstoy himself believed). Peter Andreyevich Tolstoy (*q v*) was created a count by Peter the Great. His descendant, count Nicholas Ilyich, the novelist's father, after serving as an officer in the army, married Princess Marie Volkonsky, who brought him a substantial fortune. They had five sons of whom Leo was the youngest but one The surroundings in which he grew up were those of a family of the upper middle gentry of the last of the period of serfdom This environment produced in him the "peer-and-peasant" view of life.

Early Years.—Tolstoy's mother and father died in 1831 and 1837, and he was brought up by elderly female relatives. His education was in the hands of French tutors, a state of things that was already an anachronism So his intellectual and cultural groundwork was mainly 18th century French, and his contact with contemporary Russian culture was late and unsympathetic In 1844 Tolstoy matriculated as a student of Kazan university, which was then probably the greatest seat of learning east of Berlin. But he worked little, and early developed an attitude of contempt for academic learning. He spent most of his time in society, Kazan being a social centre for the Russian gentry second only to St. Petersburg and Moscow In his old age he remembered with gratitude these years of unreflecting happiness. But his questioning mind was already asserting itself, and it is to his Kazan years that he assigns the "tremendous" influence on him of the works of Rousseau In 1847 he gave up the university and settled at Yasnaya Polyana with the intention of farming and looking after his serfs But he found himself unprepared for the work he had undertaken, and the attempt ended in failure.

The next years were mainly passed in Moscow, where he gave himself over to the dissipated and irregular life so frequently led by the young men of his class and time. But the work of self-study and self-criticism, of which his diary, started in 1847, is such a remarkable record, went on, and the idle life could not satisfy him. In 1851 he turned a new page: he went to the Caucasus and there enlisted as a *junker* (gentleman-volunteer) in an artillery unit. His time was spent in quiet garrison life in Cossack villages, diversified by hunting and occasional expeditions against the mountaineers. In 1852 he completed his first story, *Childhood*, and sent it to Nekrasov, the editor of the leading liter-

ary review, who accepted it enthusiastically and had it published at once In 1854 Tolstoy received his commission, and was transferred (on his application) to the army that was operating against the Turks on the Danube, and a few months later to Sevastopol, where he remained till the end of the siege. After the fall of the fortress he was sent with dispatches to St Petersburg, where he remained, frequenting society and literary circles, and much preferring the former to the latter. With the *littérateurs* he failed to get on Their plebeian arrogance shocked him, and he had no respect for their ideal of European progress. His resounding quarrel with Turgeniev may be taken as typical of these relations In 1857 he retired from the army.

In the same year (and again in 1860) he travelled abroad, and (like Dostoyevsky a few years later) brought back nothing but disgust with the materialistic and plutocratic civilization of the west After his second journey abroad he settled at Yasnaya Polyana, and accepted an appointment to a magistracy introduced by the Emancipation act of 1861 for the settling of land disputes between the squires and their former serfs He also started a school for peasant children on new and original lines, based on his belief in the superior value of their natural lights to the artificial standards of civilization, and published a journal (*Yasnaya Polyana*) devoted to the advancement of his pedagogical ideas But before long he gave up both magistracy and school. He was on the brink of an inner crisis.

The crisis, however, did not mature till 15 years later. it was postponed by his marriage He had been contemplating marrying for some time His romance with Valeria Arseniev had ended in nothing He was obsessed by grave misgivings and doubts before he proposed to Sophie Behrs, a young girl 16 years his junior, with whom he fell in love in 1861 He overcame them, however, and they were married in the following year

Literary Works (1852–76). Tolstoy's literary work grew out of his diary. It was primarily an attempt to lay bare the *mechanism* of the inner life, and to give clear and verbal definition to the semi-articulate processes of the consciousness His first literary attempt, *The Story of Yesterday* (1851, first published 1926) sets out to give an exhaustive account of his feelings and reactions during a given space of twenty-four hours. His first completed and published work, *Childhood* (1852), less exuberantly analytical and more conventional in form, reveals a greater command over the more intimate and elusive movements of the consciousness than had ever before been displayed in literature In the stories that followed he further perfected his instruments of analysis, often to the detriment of the imaginative unity of the work At the same time a conflict which was to remain dominant throughout his life comes to the forefront—the conflict between spontaneous, unreflecting, natural Life and the claims of reason and moral law In *The Cossacks* (written 1854, published in what the author regarded as an unsatisfactory form in 1862) the victory rests with life. natural man, unconscious of good and evil, and consequently beyond the reach of ethical reason is glorified in the Cossacks who put to shame the reflecting and impotent hero, Olenin The futility, meanness and vulgarity of civilized man is exposed again and again in *Two Hussars* (1856), *Lucerne* (1857), *Three Deaths* (1859) and in *Kholstomer* (1861), a very characteristic satire on the life of the upper classes, in which the rôle of the intelligent savage of 18th-century literature is played by a racehorse All his early work is subjective, and the reflecting and introspective character, whether his name is Olenin or Nekhlyudov (as in *Boyhood*, 1854, and *Youth*, 1857) is always Tolstoy himself The other men whose feelings are analyzed, are merely types of "man in general" —psychological mechanisms of cause and effect, devoid of personality. Such for instance are the officers of the *Sevastopol* stories (1855) in whom Tolstoy dissects the components of fear and courage.

After his marriage Tolstoy lived at Yasnaya Polyana, passing some part of the year at Moscow and on his estate beyond the Volga. His married life was happy and prosperous His income was increased by successful farming and the sale of his books. His wife was entirely devoted to him and to her children of which she bore him nine. His inner conflict was lulled for many years by the triumph of spontaneous life over questioning reason His philosophy in those years was "that one should live so as to have the best for oneself and one's family," and not try to be wiser than Life and Nature.

This philosophy found its full expression in the first of his few great novels, *War and Peace* It was commenced in 1864 and completed in 1866 After that he turned again for a time to pedagogical writings, and made several attempts at other historical novels, including one on Peter the Great, that remained unfinished, because of the invincible repulsion aroused in him by the proposed hero In 1873 he began *Anna Karenina*, which appeared in instalments from 1875 to 1877 Towards the end of his work on this second of his great novels he entered on the prolonged and fateful crisis that resulted in his conversion. Indications of its approach are clearly visible in the latter part of the novel

War and Peace and *Anna Karenina* are Tolstoy's masterpieces They mark, in a certain sense, the highest point reached in its development by the modern realistic novel Literary realism attains in them its goal. an adequacy of the verbal pattern to the living reality which ultimately produces the feeling, familiar to readers of Tolstoy, that his characters are to be classified with people in flesh and blood not with other characters in fiction This supreme achievement was largely prepared for by his previous apprenticeship, but *War and Peace* marks an enormous advance over all that had preceded it The countless characters that fill the stage are seen not from outside only, but from the inside The women in this respect are particularly remarkable, and among them most of all Natasha who is the centre of the novel, the embodiment of its philosophy, the quintessence of spontaneous nature-wise mankind Nor does the author introduce himself so crudely as he does in his earlier work, but is transformed into the two distinct and objective characters of Prince André and of Pierre With its world of characters, and against its vast background of Russian and European history the novel is a real piece of life, transformed by art The novel is markedly optimistic, and has not without propriety been described as an idyll of the Russian landed gentry Not that the horrors of life are entirely absent but they are overcome by the beneficent influence of a benevolent Life-god presiding over the action The idyllic atmosphere is preserved in the greater part of *Anna Karenina*, which as a whole marks no advance on *War and Peace*, though each of the individual characters (and again especially the women) come up to the same level, and even, perhaps, present a greater variety of persons entirely different from the author and seen from inside

His Conversion.—About 1876 Tolstoy began to feel uneasy about the unreflecting and prosperous life he was leading, the thought of approaching death grew into an invincible obsession, and the passionate craving for a religious justification of his life became the dominating force in him At first he turned to the orthodox faith of the people, hoping that a religion that made so many millions happy in the midst of their misery would save him, but the proud rationalism of his mind could not accept its rites and fasts, he renounced the Church, and out of his own reading of the Gospels gradually evolved a new Christianity, from which all the metaphysical and non-ethical elements were eliminated The decisive stage in this conversion, he tells us, was the moment when he realized that the whole message of Christ was contained in the words (Matt 5, 39) "that ye resist not evil." This doctrine of non-resistance became the foundation of the creed which soon became known as Tolstoyism (tolstovstvo)

It is necessary to distinguish two stages in this conversion: the initial pang of despair. and disgust with unjust and fleshly life, and the subsequent efforts to reduce this essentially mystical and incommunicable experience to a logical and consecutive doctrine Tolstoy gave a complete account of his conversion in *A Confession* (written 1879, revised 1882, published 1884). It is a work of great imaginative sincerity and tremendous rhetorical power worthy to rank by the side of the *Confessions* of St Augustine But the initial and more essential stage of despair is recorded with even greater power in a fragment, posthumously published, *The Memoirs of a Madman* (1884). The same experience is at the base of the two greatest imaginative works of his old age—*The Death*

of Ivan Ilyich (1884) and *Master and Man* (1895).

At first Tolstoy took no steps to propagate his new faith. It was not till after the revelation of social misery he had in a visit to the Moscow slums that his religion assumed a definitely social coloring, and not till his intimacy with V. G. Chertkov that "Tolstoyism" became an organized sect, and began to acquire proselytes This happened in 1884

Tolstoy's Teaching.—Tolstoy's religion expounded in *What I believe in,* and in *A Short Exposition of the Gospels,* is based on the natural light immanent in the human conscience which reveals to us the God that is the supreme Good and Reason God is not personal, and there is no personal immortality Jesus was a great man, whose teaching is true not because he was the Son of God, but because it coincides with the light of the human conscience. The Buddha and other men were as great, and Jesus holds no monopoly of the truth Tolstoy advanced no metaphysics and no image of the world order His religion is purely anthropocentric. God and the Kingdom of God are "inside us." The aim of man is to achieve happiness, which can be done only by doing right, by loving all men, and by freeing oneself from the appetites of greed, lust and anger All forms of violence are equally wicked. Not only war but all forms of compulsion inherent in the State are criminal. The true Christian must abstain from participating in them; he must refuse conscription; he must not accept any work under the State; he must not sit on a jury. Opposing the State with violence is also wicked and cannot lead to any better forms of life Revolutionary activity, though it may be based on the good feeling of love for the oppressed, is evil because it breeds hatred and violence. The social order can become better only when all men have learned to love each other. Still there is a great difference in Tolstoy's attitude to the State and to the Revolutionaries, he disapproves of the latter, but all the force and bitterness of his invective is kept for the former Property, as the gratification of greed and lust and the assertion of a single man's monopoly over things that belong to all, is wicked. It is the chief source of violence and so on. The rich have built up a corrupt and artificial civilization, and created for themselves fictitious values, which must be got rid of The poor, however demoralized by servitude, have preserved their good nature in greater purity because they have not been corrupted by the artificial culture of the rich. Love and compassion must be extended to all living things, and abstention from the flesh of slaughtered animals is a characteristic tenet of Tolstoyism So are abstinence from intoxicants and drugs (particularly tobacco), the artificial demand for which was created by a corrupt civilization, and which dim the natural conscience of man.

Tolstoy can hardly be called a social reformer for he advanced no practical proposal for the improvement of social conditions. He did not believe in the possibility of reform in the accepted sense of the word. The first duty of the true Christian being is to abstain from living by the work of others, and from taking part in the organized violence of the State. The only practical measure he advocated was the solution of the land question by means of the land tax of Henry George. His disapproval extended to the organized violence of Western capitalistic democracy as well as of Russian autocracy.

On the whole, the direct influence of Tolstoy's teaching in Russia was not great His disciples were never numerous (and seldom of a very high quality) He established relations with many dissenting Russian sects, but most of these (*e.g*, the ***Doukhobors,*** *q v*) were essentially alien to him in spirit. His larger influence, however, was immense, and very soon crossed the frontier. In the last 15 or 20 years of his life he was probably the most venerated man in the world His fame reached into China and India as well as Europe and America Visitors from all ends of the world made Yasnaya Polyana a new Mecca

From the first, the Russian Government viewed Tolstoy's new activity with hostility. But it never attempted to do anything against him. Some of his more anti-Orthodox writings, as well as some of his bitterest attacks on the Romanoff dynasty had to appear abroad. But what appeared in Russia was quite sufficient for a complete acquaintance with his teaching. In 1901 the Synod of the Russian Church excommunicated him,—an act which has been much misinterpreted and which merely registered a fact he had himself proclaimed many years earlier, viz., that he had ceased to belong to the Church. On the other hand many of Tolstoy's followers suffered imprisonment and banishment to Siberia chiefly for refusal of military service.

Tolstoy's conversion changed his attitude to his literary creation He did not abandon it, nor did it deteriorate in quality, but it became different, so did his views of its social and moral function. They are contained in *What is Art* (1896), one of the most remarkable books ever written on the subject. Art, according to Tolstoy, is a means of emotional communion, a means by which the artist "infects" other people with feelings he has himself experienced. If this "infection" does not take place there is no art. If it is limited to a small number of persons of the same class, time or nationality as the author, it is negligible and inferior art; if the appeal extends to mankind in general, but the feelings thus communicated are evil feelings it is genuine but evil art; if the feelings are good, it is good art and if they are the highest feelings possible, the religious feelings of love and compassion, it is the highest form of all, religious art. The application of these standards led Tolstoy to reject or to minimize by far the greater part of modern art and literature, including his own early work, which had exalted the life of the rich and idle. This change of attitude went hand in hand with a change in his literary taste He rejected the "superfluous detail" of realism not only because it limited the appeal of literature to those familiar with the society described, but because it ceased to satisfy him aesthetically Already in 1873 he had written some stories for the people, in which everything that was not essential for the narrative development had been rigorously eliminated. From 1884 onwards he wrote a number of new stories of the same kind, masterpieces of chaste and classical narrative technique at the service of one unifying and crystallizing idea, the idea of ethical Christianity

The same method, on a larger scale, is applied in *Father Sergius,* in *The False Coupon,* and in *Hadji-Murād* (1896–1904) which was the favourite work of his old age and which he intended as an example of good art appealing to the sense of human brotherhood, though not to the highest religious feelings

Apart from these works stands *Resurrection* (published in 1899–1900) in which he returned to his old "superfluous-detail" and which consequently failed to satisfy him. It contains beautiful passages in the idyllic style of *War and Peace,* and pages of powerful satire on the evil social order, but it falls short of being a masterpiece

The most important imaginative work of his last period are the stories based on his inner experience—those connected with his conversion (*The Death of Ivan Ilyich, Master and Man, The Memoirs of a Madman*), and those in which he embodied his experience of sex, the *Kreutzer Sonata* (1889) and *The Devil* (1889, pub. 1911). The former group in particular stands in importance by the side of *War and Peace* The atmosphere pervading them is totally different: they are as grimly tragical as the earlier novel is idyllic. They are on a level with the greatest religious writings of the world.

Tolstoy's plays (with the exception of a comedy written in 1863 and published in 1926) all belong to the period after his conversion. They include *The Power of Darkness* (1889), a powerful drama of peasant life; *The Fruits of Enlightenment* (1st ed., 1891; 2nd ed., 1911), a light comedy satirizing the fads of "society," and *The Living Corpse* (pub. 1911), one of his last writings in which there is a mellowness of old age, and in which the character creator of *War and Peace* makes his last appearance.

Last Years.—Tolstoy's conversion led to his adopting a new mode of life—he dressed like a peasant, did much manual work learned bootmaking and adopted a vegetarian diet. His wife and children (except his youngest daughter, Alexandra) remained hostile to his teaching and the Countess Tolstoy would not hear of his renouncing his worldly belongings which, she maintained, be held in trust for his children. So he made over all his property (including the copyright of his works written before 1880) to her. The paradoxical situation arose of the preacher of poverty and

abstention continuing to live in affluence surrounded by a family who disapproved of his views, but adored him. The first tension between him and his wife was followed by a rapprochement, cemented by the birth in 1886 of a sixth son. But the death of the little boy at the age of seven was followed by an increasing estrangement between husband and wife. She grew increasingly hysterical, embittered and tactless, and life at Yasnaya became a hell, a constant state of war between the family and followers of Tolstoy, between Countess Tolstoy and Chertkov Tolstoy suffered deeply from the incongruity of his position at home At last on Oct. 28, 1910, he left home secretly at night with his daughter Alexandra He had no particular aim in view. His health broke down at Astapovo (gov. of Ryazan) He was laid up there in the station-master's room, and he died on Nov. 8 (21), 1910. He was interred at Yasnaya, without a Christian burial.

BIBLIOGRAPHY.—An edition of the complete works of Tolstoy, translated by Louise and Aylmer Maude is in progress in the Oxford University Press, versions of most of Tolstoy's works, by the same translators, are available in the *World's Classics* series of the same press Also: *Complete Works*, 24 volumes, tr. Leo Wiener, Boston and London (1904–05); *Works* (incomplete) 7 vols, tr. Constance Garnett (1901–04, and 1911–15); *The Dramatic Works*, tr. N. H. Dole, London and New York (1923); posthumous works. *Hadji-Muràd, and other stories; The Forged Coupon, and other stories; Father Sergius and other stories*, ed C. Hagberg Wright (1911–12); *Stories and Dramas, hitherto unpublished*, tr Lyd a Turin, etc (London and New York, 1926); *Tolstoy on Art* (containing all Tolstoy's writings on the subject), by Aylmer Maude (1925, Boston, 1924).

Diaries and Letters: The Diaries of Leo Tolstoy [1852–77], tr. Hogarth and Sirnis (1917); *The Private Diary of Leo Tolstoy* (1853–57) tr L and A. Maude (1927), *The Journals of Leo Tolstoy* (1895–99), tr. Rose Strunsky (1917), *Tolstoy's Love Letters*, tr Koteliansky and Virginia Woolf (1923)

Recollections of Tolstoy· Ilya Tolstoy, *Reminiscences of Tolstoy, by his son* (1914), Maxim Gorky, *Reminiscences of Tolstoy* (1920), V. G. Chertkov, *The Last Days of Tolstoy* (1922), A B. Goldenveizer, *Talks with Tolstoy* (1923), Leo Tolstoy, junior, *The Truth about my father* (1927), Aylmer Maude, *Family views of Tolstoy* (1926).

TOLSTOY, ALEXEI KONSTANTINOVICH, COUNT (1817–1875), Russian novelist, dramatist and poet, was a distant relation of Leo Tolstoy Born at St. Petersburg on Sept 5, 1817, and brought up on his uncle's estate at Tchernigoff, which he inherited in 1836, he was a playmate of the Emperor Alexander II. He studied at the university of Moscow, and was afterwards attached to the Russian Legation at Frankfurt and served in the Crimean War He held various court appointments, and spent much time in western Europe He died at his Tchernigoff estate, Krasni Rog, on Oct 10, 1875 With his two cousins Zhemchuzhnikov, Tolstoy wrote between 1853 and 1863 much satirical nonsense-verse under the joint pseudonym of a fictitious civil servant, Kosma Prutkov. He also wrote some magnificent lyric poetry; one of his most famous pieces, a paraphrase of the lament for the dead in the Russian church service, is translated by Maurice Baring in the *Oxford Book of Russian Verse.* Outside Russia, however, Alexei Tolstoy is best known by his historical romance, *Prince Serebrany* (1863) (Eng trans. by C A Manning, 1927), and his dramatic trilogy *Death of Ivan the Terrible* (1866; Eng trans. by A. Hayes, 1926); *Tsar Feodor Ioannovich* (1868; verse trans A. Hayes, 1924), and *Tsar Boris* (1870) Some of his poems are translated in C T Wilson's *Russian Lyrics in English Verse* (1887); Anglo-Russian Literary Society, Nos. 21, 23, 25, and J Pollen's *Rhymes from the Russian* (1891)

See A. Lirondelle, *Le Poète Alexis Tolstoï* (1912).

TOLSTOY, PETR ANDREEVICH, COUNT (1645–1729), Russian statesman, was the son of the *okolmnichy* Andrei Vasilevich Tolstoy.

Even before Poltava, Tolstoy had the greatest difficulty in preventing the Turks from aiding the Swedes, and when Charles XII. took refuge on Turkish soil he instantly demanded his extradition. This was a diplomatic blunder, as it only irritated the already alarmed Turks; and on Oct. 10, 1710, Tolstoy was thrown into the Seven Towers, a proceeding tantamount to a declaration of war against Russia. On his release from "this Turkish hell," in 1714, he returned to Russia, was created a senator, and closely associated himself with the omnipotent favourite, Menshikov. In 1717 his position during Peter's reign was secured once for all by his successful mission to Naples to bring back the unfortunate tsarevich Alexius, whom he may be said to have literally hunted to death

Tolstoy materially assisted Menshikov to raise the empress consort to the throne on the decease of Peter (1725), and the new sovereign made him a count and one of the six members of the newly instituted supreme privy council When Menshikov, during the last days of Catherine I, declared in favour of Peter II, Tolstoy endeavoured to form a party to promote the accession of Catherine's second daughter, the tsarevna Elizabeth. But Menshikov was too strong and too quick for his ancient colleague On the very day of the empress's death (May 11, 1727), Tolstoy, now in his eighty-second year, was banished to the Solovetsk monastery in the White Sea, where he died two years later

See N. A. Popov, "Count P A. Tolstoy" (Russ) in *Old and New Russia* (St Petersburg, 1875), and "From the Life of P. A Tolstoy" (Russ) in *Russian Reporter* (St Petersburg, 1860); R N. Bain, *Pupils of Peter the Great* (London, 1897); and *The First Romanovs* (London, 1905). (R. N. B)

TOLTEC, a people frequently referred to in Aztec legend as formerly dominant in the region of the valley of Mexico, and associated with the ruins at Tollan (now Tula), that is, "Toltec place," but literally, place of tules or rushes Their greatest preserved monuments, however, are at San Juan de Teotihuacan 30m north-east of Mexico city; and the terms Toltec and Teotihuacan are used by different archaeological schools as names of the same period. Cholula, one of the large cities of Mexico in 1519, was associated with the Toltec traditionally; and in a measure Tezcoco In Yucatan, Toltec influence is visible in ball courts, art style, etc, in the late Maya cities, especially Chichen Itzá The legends or myths of the hero Quetzalcoatl (Kukulcan in Maya) associate him with the Toltec; and as he was the reputed institutor of higher culture, the Toltec were considered the first bearers of arts and knowledge, which is probably true for the region Tula-Mexico-Cholula Brinton looked upon the Toltec as a mythical invention by the Aztec, a view significant only as a valid reaction against a former too credulous acceptance of the details of native tradition The Toltec presumably were Nahua speaking; they may have been at their zenith about A D 900, and suffered decline about A D. 1100

TOLUCA, a city of Mexico and capital of the State of Mexico, on the south-west border of the Anahuac plateau, about 8,650 ft. above sea-level. Pop (1921) 34,265 Toluca is on the Mexican National railway, 45 m west-south-west of the national capital Its situation gives it a cool climate The Government has a meteorological station here and a national college. The Nevado de Toluca, an extinct volcano, rises to a height of 14,950 ft on the south-west side of the town

TOLUENE or Methylbenzene, a constituent of the light oils distilled from coal tar (*q v*), is a colourless mobile liquid boiling at 111° C/760 mm and having a density of 0 8812 at 4° C. It is insoluble in water but dissolves readily in alcohol or ether Toluene (*Ger* Toluol), an aromatic hydrocarbon (*see* CHEMISTRY, ORGANIC), is an important starting point in the manufacture of intermediates and synthetic colouring matters (*See* BENZALDEHYDE; BENZOIC ACID, DYES, SYNTHETIC) Its mononitro-compounds furnish ortho- and para-toluidines, two valuable bases employed in the production of magenta and other aniline dyes During the World War toluene was in such great demand for the manufacture of the high explosive trinitrotoluene (*see* T N T) that its output from coal tar had to be supplemented by supplies from other sources such as Borneo petroleum

On sulphonation toluene yields mainly two sulphonic acids, of which toluene-ortho-sulphonic acid is employed in the production of saccharin (*q v.*)

Originally discovered by Pelletier (1838) in an oil obtained from the resin of *Pinus maritima* it was subsequently prepared by Sainte-Claire Deville (1841) on distilling tolu balsam It is to the

latter circumstance that the hydrocarbon owes its name. Its relationship to benzene was established by acting with sodium on a mixture of methyl iodide and bromobenzene and also by condensing benzene and methyl chloride in the presence of dry aluminium chloride.

Oxidation of toluene leads successively to benzaldehyde and benzoic acid, whereas its hydrogenation furnishes hexahydrotoluene *p-tolualdehyde*, a pungent oil (b p 204° C), results from the interaction of toluene with carbon monoxide and hydrogen chloride in the presence of aluminium and cuprous chloride, or from hydrogen cyanide and hydrogen chloride with aluminium chloride.

See T E Thorpe, *Dictionary of Applied Chemistry*, Vol VII, 1927 (G T. M)

TOMA, a small, light-complexioned, muscular folk, in French Guinea, who speak a language related to the Mande-Fu group

See Gamory-Dubourdeau, "Notice sur les coutumes des Toma," *Bulletin, Comité Études—Hist. et Scient d'Afrique Occidentale* (1925).

TOMASZÓW, an industrial town of Poland, in the province of Lodz Pop (1921), 28,300 It has woollen mills, iron-works and steam flour-mills, and is the centre of the silk industry

TOMATO, the name applied to various species of plants known botanically as *Lycopersicum*, a genus of the family Solanaceae, to which the potato, tobacco and egg-plant also belong There is doubt as to the distinction of the cultivated species of tomato *L esculentum* includes the varieties of the common tomato, *L pimpinellifolium* is the currant tomato, *L cerasiforme* the cherry tomato and *L pyriforme* the pear tomato, though the last two are sometimes considered mere varieties of *L esculentum* The common tomato with large fruits containing a number of cells is *L esculentum* var *commune;* the red or yellow fruits are of the nature of berries The plant has been much altered by cultivation and now more than 150 so-called varieties are on the market The seeds of the tomato were brought by the Spaniards from South America and the fruit was for some time known as "love apple" Enormous quantities, both fresh and canned, are now consumed annually and it is very extensively grown in Great Britain and the United States Large quantities are grown under glass in the Lea Valley district and the Worthing district in England, and also in the Channel islands (*See* VEGETABLE)

See L. H Bailey, *Standard Cyclopedia of Horticulture* (1914–27) and *Manual of Cultivated Plants* (1924) and W W Robbins, *Botany of Crop Plants* (1924).

TOMB, a broad term for any grave or funerary structure, especially one of relatively large size or with considerable decorative richness Thus the tumuli or barrows used in many parts of northern and eastern Europe during the bronze and early iron age, the structures over a grave, common in Roman, mediaeval and modern times, structures containing a sarcophagus in which the body is placed, and those richly ornamented sarcophagi in niches or shrine-like constructions in the interiors of churches, all come under the general name, tomb. (*See* also BARROW, BURIAL AND FUNERAL RITES; CAIRN, MAUSOLEUM; SARCOPHAGUS, TUMULUS) Since knowledge of the past is so largely gleaned from ancient burials, tombs play a most important part in all archaeological study, particularly in that of very ancient times, prior to written records (*See* ARCHAEOLOGY)

Ancient.—Architecturally, tombs reach importance only with the development of Egyptian civilization, towards the end of the 4th millennium B C The early dynasty tombs are largely of the mastaba (*q v*) type, consisting of low, flat-roofed, masonry structures, with the tomb chamber itself sunk in the rock below, royal tombs of this period almost always took the form of pyramids (*q v*) During the middle kingdom, rock-cut tombs in cliff sides largely superseded the earlier types, they were usually fronted by a colonnaded porch In the later empire, even this exterior embellishment disappeared, and tombs were merely chambers cut deep in the rock, at the ends of long tunnels, with inconspicuous entrances. Many types of tomb are found in western Asia, both prior to and after the dominance of Hellenic Greek culture. Those of Lydia and Lycia are particularly remarkable. In Greece the most interesting type of pre-Hellenic tomb is the tholos or bee-hive type, roofed in corbelled masonry, and evidently imitating in shape a primitive house form The so-called tholos of Atreus at Mycenae (*c* 1200 B C.) is typical Other rectangular types are, however, found On the Greek mainland, during the Hellenic period, tombs were largely superseded by simple graves or funerary urns, the gravestones, or stele, were of great beauty though small in size In Asia Minor, on the other hand, tombs were often large and lavish The climax was reached in the mausoleum (*q v.*) erected to enshrine the body of King Maussolos (353 B C) In the Roman world tombs of every type are found The Italians early built elaborate tombs, especially famous are those at Cervetri and Volterra, and others at Vulci and near Perugia. These Etruscan tombs are sometimes of tholos type, sometimes tumuli, and sometimes represent the rectangular interiors of Italian houses, and are richly carved and painted A similar variety is found in Roman tombs There are pyramids (Gaius Cestius, Rome, probably prior to 12 B C), circular or tumulus types like that erected by Augustus for himself in Rome (28 B C) and the much larger and more monumental tomb of Hadrian, now the castle S Angelo, and rectangular, shrine-like structures, like the so-called tomb of Absalom at Jerusalem (? 2nd century A D), or the tomb of Annia Regilla at Rome (end of the 2nd century A D) The greater number of Roman burials were, however, in columbaria (*q v*)

Mediaeval.—In the mediaeval period, owing to the crowded conditions of churchyards, exterior tombs are rare, but tombs of privileged persons within churches common An exception is the group of arcaded tombs of the Scaliger family at Verona (14th century) The interior tombs, particularly common in England, took the form of sarcophagi, bearing a recumbent effigy, like the crusaders' tombs in the Temple church in London, or of little shrines enclosing a sarcophagus, like Prior Rahere's tomb in the church of S Bartholomew the Great, London (1400–05) Of the shrine tombs, the most interesting are the royal tombs in Westminster Abbey, London

Renaissance.—The early Renaissance period saw many tombs of great beauty constructed throughout Europe In Italy, the most common type was a decorated niche containing a sarcophagus An exquisite example is the Marsupini tomb in S Croce, Florence (*c* 1460), by da Settignano The sarcophagus type is also found One of the first monuments in England showing Renaissance inspiration is the tomb of Henry VII in Westminster Abbey, by Torrigiano, the same is true in France of the tomb of the children of Charles VIII in Tours cathedral (1506), by J Juste and M Colombe, and a similar rôle is played in Spain by the "Tomb of the Catholic Kings," in Granada, the tomb of Ferdinand and Isabella, by Fancelli (1517) and of Don Felipe and Donna Juana, by Ordóñez (1520) The most interesting groups of later Renaissance tombs are those of the Venetian churches, and the papal tombs in S Peter's, Rome, the royal tombs in S Denis, near Paris, and the later tombs in the aisles of the chapel of Henry VII, Westminster Abbey In the 18th century, throughout Europe, wall monuments in churches generally superseded tombs, there is, however, a new development of exterior tombs, usually taking the form of a richly decorated sarcophagus, sometimes known as table tombs, common both in England and her colonies.

Oriental.—In Mohammedan countries tombs were reserved for great personages or royal families The richest and most monumental are the domed turbehs of the Turkish sultans in Constantinople, and the tombs built by the Muslim rulers of India, especially the great tomb of Mahmoud at Bijapur (1626–60) and the Taj Mahal (*q v*) at Agra (1632–47)

Chinese tombs vary according to the locality Near Foochow there is a characteristic group in which a cylindrical stele is placed on a terrace in the middle of a crescent-shaped embankment Farther north, near Hangchow, the cylindrical stelae are lower and topped with domes, and a semi-circular wall frequently takes the place of the embankment. The great imperial tombs are entirely different and resemble each other, whether at Nanking, in the western hills near Peking, or in Mukden. They all consist of a series of colonnaded halls crossing a great main axis,

bordered with statues of beasts and men. The royal tombs at Tokyo, in Japan, resemble the Chinese tombs in having a series of great halls, and in being rather temples than simple tombs; the arrangement, however, is more informal, and a characteristic feature of the Japanese tombs is the hundreds of votive, stone lanterns which stand in the courts.

Modern.—The tomb of Napoleon in the church of the Invalides, Paris (1843–61) by Visconti, is a characteristic modern expression of a tomb which has become a national shrine More recent tombs show a continuous development towards an increasing simplicity and the attempt to gain emotional effect by perfection and sincerity rather than by grandeur. (T. F H)

TOMMASINI, VINCENZO (1880–), Italian composer, was born in Rome on Sept. 17, 1880. He studied at the Liceo in Rome and later became assistant director of the Accademia di S. Cecilia His first work of importance was the string quartet of 1910; this was followed by the "Erotic poem" for orchestra and the comic opera *Uguale fortuna* in 1911. The symphonic poem, *Chiari de luna* was produced in 1916, and in 1917 he achieved his great triumph with *The Good-humoured Ladies,* a ballet, founded on Goldoni's comedy. The original performance was in Rome and it has since been played in the principal music centres by Diaghilev's company with great success For the music Tommasini took a selection of the sonatas of Domenico Scarlatti, orchestrating them with much skill and charm Later works are *Il beata regno* (1921) and *Paesaggi Toscani* (1923).

TOMPKINS, DANIEL D. (1774–1825), American politician, was born at Scarsdale, Westchester county, N Y , on June 21, 1774 He graduated at Columbia college in 1795, and was admitted to the bar in 1797 In 1803 he was a member of the State assembly, and in 1804 he was elected to the national House of Representatives, but became a judge of the State supreme court, and served as such until 1807 He was governor of New York in 1807–17; and in 1817–25, during both terms of President James Monroe, was vice-president of the United States In March, 1812, under the authority of the New York constitution of 1777, he prorogued the legislature—the only instance of the exercise of this power During the War of 1812 he was active in equipping and arming the New York militia For this purpose he borrowed much money on his personal security, and sometimes neglected to secure proper vouchers Later the State comptroller announced a shortage of $120,000 in the military accounts, but Tompkins claimed that the State owed him $130,000 Later investigations disclosed that the State actually owed him more than $90,000 He died on Staten Island, N Y , on June 11, 1825

The *Military Papers of Daniel D Tompkins, 1807–1817* (1898–1902) were published by the State. *See* D S Alexander, *Political History of New York,* vol 1 (1906).

TOMPKINSVILLE, a former village of Richmond county, New York, U.S A , since 1898 a part of the borough of Richmond, New York city It is on the north-east shore of Staten Island in New York bay, about 5½ m S by W of the southern extremity of Manhattan Island.

TOMSK, a town of the Siberian Area of the Russian S F S R , in 56° 30′ N , 85° 12′ E , on the right bank of the Tom river and on both sides of its tributary the Ushaika, at an altitude of 485 feet. Pop. (1926) 92,485. The river is frozen from Nov 17 to May 13. A branch line links Tomsk with Taiga on the trans-Siberian railway The town was founded in 1604, but did not become important until 1824, when gold was found in the district and a gold smelting laboratory was later established in the town; the gold industry is now rapidly declining. The town is an educational centre, with a university, library and museum

TOMSKY, pseudonym of Michael Pavlovich Efremov (1880–), Russian politician, born on Oct. 19, 1880, in St Petersburg (Leningrad), was the son of a workman, and became a factory hand at the age of 12 In 1904 he joined the Bolshevik party and was a member of the Reval council of workers' deputies during the revolution of 1905 Between 1906 and 1917 Tomsky suffered various terms of imprisonment and deportation, and was finally sentenced to five years' hard labour in the Moscow Butyrka prison, followed by deportation for life to Siberia Released by the revolution of 1917, Tomsky took part in the Bolshevik July rising in St. Petersburg and the October revolution in Moscow. Afterwards he devoted himself particularly to trade union work, and edited *The Metal Workers' Review.* He was elected member of the Moscow trade union council, and in 1918 became president of the all-Russian central trade union council, with a short interval when he acted as representative of the Soviets in Turkestan On the reorganization of the R S F S R. into the U S S.R he became a member of the central executive committee of the U S S.R.

Tomsky was vice-president of the Soviet delegation to London in 1924, and a member of the delegation to Paris in 1926. He acted as general secretary of the provisional international council of the trade unions from its formation on Aug. 1, 1920, to May 1921, and addressed the British trade unions at the conferences at Hull (Sept. 1924) and Scarborough (Sept. 1925)

His most important writings and addresses are included in the following volumes. *Die Neuen Aufgaben der russischen Gewerkschaften* (1922) , *Der gegenwartige Stand der Gewerkschaftsbewegung in Russland* (1923) , *Getting Together: Speeches Delivered in Russia and England: 1924–25* (1925).

TONALITE, in petrology, a rock of the diorite class, first described from Monte Adamello near Tonale in the Eastern Alps. It may be described as a quartz-diorite containing biotite and hornblende in nearly equal proportions. The principal felspar is plagioclase, but orthoclase occurs also, usually in small amount. With increase in silica, the tonalites pass into the granodiorites (*see* GRANITE)

The hornblende of the diorites is green, sometimes with a tinge of brown; the biotite is always brown and strongly pleochroic Often these two minerals are clustered together irregularly or in parallel growths They have generally a fairly strong tendency to idiomorphism, but may sometimes enclose plagioclase felspar in ophitic manner. Both of them decompose to chlorite, epidote and carbonates The plagioclase felspar, which may form more than one-half of the rock, is andesine or oligoclase; simple crystals are rare, the majority being complex growths with centres of felspar rich in lime, while in the external zones the proportion of soda felspar increases greatly. The inner portions have often well-defined, but very irregular, boundaries, and are sometimes sponge-like, with the cavities filled up with a later, more acid, deposit This seems to indicate that growth has taken place in stages, alternating with periods when the crystallized felspar was corroded or partly dissolved The orthoclase sometimes forms irregular plates enclosing individuals of plagioclase Quartz occurs both in irregular simple grains and as micropegmatite. Occasionally pale green pyroxene is visible in the centre of crystals of dark green hornblende. The accessory minerals apatite, magnetite and zircon are always present, and very common also are orthite in coffee-coloured zonal prisms practically always encircled by yellow epidote, and reddish-brown crystals of sphene, simple or twinned

Externally tonalites are very like granites but are usually darker Towards their margins the larger alpine masses of tonalite often assume banded or gneissic facies, due apparently to movement during intrusion In the south of Scotland (Galloway district) they accompany hornblende- and biotite-granites, hornblende- and augite-diorites. The newer granites of the Highlands of Scotland in many places pass into tonalites, especially near their margins, and similar rocks occur in Ireland Grano-diorites have been described from California, and rocks of similar character occur in the Andes, Patagonia and Lesser Antilles Tonalites are also said to be frequent among the igneous rocks of Alaska (J S. F.)

TONAWANDA, a city of Erie county, New York, U S A , on the Niagara river, 11 m. N of Buffalo, at the western terminus of the State Barge canal. It is served by the Erie, the Lehigh Valley, the New York Central and electric railways. Pop (1920) 10,068 (20% foreign-born white); 1928 local estimate 11,300 Tonawanda and North Tonawanda (*q.v.*), on the opposite side of the canal, though separate municipalities, form practically one community. They have a fine harbour, electric power from Niagara Falls and many large manufacturing industries Tona-

wanda was incorporated as a village in 1854 and as a city in 1903. The name is an Indian word, said to mean "swift water."

TONBRIDGE, a town of Kent, England, 27 m. S.S.E. of London by the S. railway. Pop. (1921) 15,947. It stands above the River Medway, which is crossed by a stone bridge erected in 1775. There are remains of an ancient castle of the Early Decorated period. The castle was formerly defended by three moats, one of them formed by the Medway. Tonbridge school was founded by Sir Andrew Judd, lord mayor of London in the time of Edward VI, and was rebuilt in 1865.

TONE, THEOBALD WOLFE (1763–1798), Irish rebel, the son of Peter Tone, a Dublin coachmaker, was born in Dublin on June 20, 1763. He entered Trinity college, at twenty-two he married Matilda Witherington, a girl of sixteen, took his degree in 1786 and went to London He was entered at the Middle Temple, and afterwards read law in Dublin, being called to the Irish bar in 1789. Tone wrote two pamphlets in 1790, one of which, *A Review of the Conduct of Administration* attracted some notice from the Whigs

Tone made the acquaintance of Thomas Russell (1767–1803), Napper Tandy (*q v*) and others, and the society of the "United Irishmen" was formed (1791). The original purpose of this society was simply the formation of a political union between Roman Catholics and Protestants, to secure parliamentary reform; it was only when that object appeared to be unattainable by constitutional methods that the majority of the members adopted the more uncompromising opinions which Wolfe Tone held from the first, and conspired to establish an Irish republic by armed rebellion Tone desired to root out the popular respect for Charlemont and Grattan, and to transfer to more violent leaders the conduct of the national movement Grattan was a reformer and a patriot without a tincture of democratic ideas, Wolfe Tone was a revolutionary whose principles were drawn from the French Convention Grattan's political philosophy was allied to that of Edmund Burke, Tone was a disciple of Danton and Thomas Paine.

In 1794 the United Irishmen, persuaded that their scheme of universal suffrage and equal electoral districts was not likely to be accepted by any party in the Irish parliament, began to found their hopes on a French invasion An English clergyman named William Jackson, who had imbibed revolutionary opinions in France, came to Ireland to negotiate between the French committee of public safety and the United Irishmen For this emissary Tone drew up a memorandum on the state of Ireland, which he described as ripe for revolution; the paper was betrayed to the government, and in April 1794 Jackson was arrested on a charge of treason. Several of the leading United Irishmen, including Reynolds and Hamilton Rowan, immediately fled the country; the papers of the United Irishmen were seized; and for a time the organization was broken up. Tone, who had not attended meetings of the society since May 1793, remained in Ireland till after the trial and suicide of Jackson in April 1795 He was enabled to make terms with the government, stipulating only that he should not be called on to give evidence against Rowan and the others, and was permitted to emigrate to America, where he arrived in May 1795.

He went to Philadelphia where he met fellow exiles, and the French minister, Adet, who gave him letters of introduction to the Committee of Public Safety in Paris In February 1796 he arrived in Paris and had interviews with De La Croix and L. N. M. Carnot, who were greatly impressed by his energy, sincerity and ability. A commission was given him as adjutant-general in the French army, which he hoped might protect him from the penalty of treason in the event of capture by the English. He drew up two memorials representing that the landing of a considerable French force in Ireland would be followed by a general rising of the people, and giving a detailed account of the condition of the country. The French directory, which possessed information from Lord Edward Fitzgerald (*q.v*) and Arthur O'Connor confirming Tone, prepared to despatch an expedition under Hoche. On Dec. 15, 1796, the expedition, consisting of 43 sail and carrying about 15,000 men, sailed from Brest. Tone, who accompanied it as "Adjutant-general Smith," had the greatest contempt for the seamanship of the French sailors, which was amply justified by the disastrous result of the invasion. The ships were dispersed by a storm off the coast of Kerry.

But the Dutch fleet was delayed by bad weather, and before it put to sea in October, only to be crushed by Duncan in the battle of Camperdown, Tone had returned to Paris; and Hoche, the chief hope of the United Irishmen, was dead. Bonaparte, with whom Tone had several interviews about this time, was much less disposed than Hoche had been to undertake in earnest an Irish expedition; and when the rebellion broke out in Ireland in 1798 he had started for Egypt. When, therefore, Tone urged the directory to send effective assistance to the Irish rebels, all that could be promised was a number of small raids to descend simultaneously on different points of the Irish coast. One of these under Humbert succeeded in landing a force in Killala bay, and gained some success in Connaught before it was subdued by Lake and Cornwallis, Wolfe Tone's brother Matthew being captured, tried by court-martial, and hanged; a second, accompanied by Napper Tandy (*q v*), came to disaster on the coast of Donegal; while Wolfe Tone took part in a third, under Admiral Bompard, with General Hardy in command of a force of about 3,000 men, which encountered an English squadron near Lough Swilly on Oct. 12, 1798.

Tone, who was on board the "Hoche," refused Bompard's offer of escape in a frigate before the action, and was taken prisoner when the "Hoche" was forced to surrender At his trial by court-martial in Dublin, Tone made a manly straightforward speech, avowing his determined hostility to England and his design "by fair and open war to procure the separation of the two countries," and pleading in virtue of his status as a French officer to die by the musket instead of the rope He was, however, sentenced to be hanged on Nov 12; but on the 11th he cut his throat with a penknife, and on Nov. 19, 1798, he died of the wound He was buried in Bodenstown churchyard.

See *Autobiography of Theobald Wolfe Tone*, edited with introduction by R. Barry O'Brien (2 vols, 1893); R. R Madden, *Lives of the United Irishmen* (7 vols, 1842)

TONE POEM: *see* SYMPHONIC POEM

TONGA, the Tonga or Friendly Islands, an archipelago in the S. Pacific Ocean about midway between Fiji and Samoa For the geography, etc., *see* PACIFIC ISLANDS

History.—In 1616 the vessels of Jacob Lemaire and Willem Cornelis Schouten reached the island of Niuatobutabu and had a hostile encounter with the natives. In 1643 Abel Tasman arrived at Tongatabu and was more fortunate. The next visitor was Samuel Wallis in 1767, followed in 1773 by Captain Cook In 1777 Cook returned, and stayed seven weeks among the islands. In 1799 a revolution broke out, and war dragged on for many years, until finally checked by the strong rule of Taufaahau, who became king in 1845, under the name of George Tubou I In 1822 a Methodist missionary had arrived in the island, and others followed The attempt to introduce a new faith led to renewed strife, this time between converts and pagans, but King George supported the missionaries, and by 1852 the rebels were subdued. The missionaries persuaded the king to grant a constitution to the Tongans. A triennial parliament, a cabinet, a privy council, and an elaborate judicial system were established, and the cumbrous machinery was placed in the hands of a "prime minister," a retired Wesleyan missionary, Shirley Baker. Baker induced the king to break off his connection with the Wesleyan body in Sydney, and to set up a State church. Persecution of members of the old church followed, and in 1890 the missionary-premier was removed from the island by British influence.

King George Tubou died in 1893 at the age of 96, and was succeeded by his great-grandson, under the same title. In 1900 a treaty was concluded by which the king placed his kingdom under British protection. On the death of George II. (1918), Queen Salote ascended the throne. Since 1905 British coin has been legal tender in Tonga. Education has been rapidly developed: in 1924 there were 105 public primary schools.

Thomson, *The Diversions of a Prime Minister* (1894); for traditions and historical material *see* the *Journals* of the Polynesian Society (New Zealand); P. S. A. Stewart, *Handbook of the Pacific Islands* (1922).

TONGHAK or **CHUNTOKYO,** a religious system of Korea, founded in 1864. The prime object was to preserve all national customs and ideals and oppose Christianity. Its forms are those of Confucianism but its spirit and voice are those of Buddhism and Taoism. The founder, Choi Jaiwoo (崔濟愚, 1824–64), was a great classical scholar with originality in ethical thought. At 16, having lost his father and being very poor, he wandered round the country from his birthplace, Kungchu, South Korea. He was struck by the chaotic conditions, the corrupt officialdom, the poverty and superstition of farmers, the unrest and misery of the towns, and the intellectual degeneracy of the nation. All this made him feel keenly the lack of a religion which could give the people a fresh vision and courage. Buddhism had been banished to mountain solitudes in the 15th century, Confucianism was for the upper classes only, so that there was no religion that could direct the destiny of the masses.

Choi Jaiwoo's belief was that *Chun* or *Tien* (天 god), the creator of all things, made heaven, earth and man; that man is the most intelligent and noble of all creations. Everything exists because there is man, who is as great as God provided he holds fast to God-given qualities Man, in fact, is God (人乃天); they are one, not two *To* or *tao*, an infinite being, existent before the creation of the world, is the way to heavenly doctrine. Thus his teaching, *Tonghak* (東學, Eastern Learning) was called *Chun tokyo* (天道教, Heavenly Way Doctrine).

Since man is the highest of all God's creations, he must enjoy complete freedom and absolute equality. He must realize the self and develop it to be as noble as possible by emancipating body, mind and soul Man is thus the core of the universe The Kingdom of Heaven will exist on earth when all men develop intellectually, socially and spiritually, and for this goal man must pray and work. The founder was accused of heresy and executed on March 1, 1864, in Taiku, South Korea Choi Sihyung (崔時亨, 1827–99) became his successor. He preached the doctrine of his predecessor adding the precept of abstention from flesh, and organized churches throughout Korea. He was hanged for heresy on June 2, 1899 His successor, Son Pyunghi (孫秉熙, 1861–1922) led a Tonghak rebellion. He sent many students abroad and took an active part in the Revolution of 1919; he was put in jail, where he died on May 19, 1922.

The Chuntoists support a number of schools and a college and teach the ideas of western civilization as well as oriental cultural elements. They preach any sacrifice in the cause of humanity and justice. Chuntoist activity in politics and the lack of a doctrine regarding the future life have given rise among Christians to the impression that Chuntoism is not a religious sect; but Confucianism, if judged by the two latter criteria, would also be considered non-religious.

Chuntoism has grown into one of the most potent forces of Korea to-day. Its most prominent leaders are the educator, Choi Rin, and the philosopher, Paik Inho. (Y. K.)

TONGKING, a province of French Indo-China, and protectorate of France, situated between 20° and 23½° N. and 102° and 108½° E., and bounded by China, British Upper Burma, Laos, Annam, and the Gulf of Tongking. Area, 40,530 sq.m. The population is 7,401,912, including 9,143 Europeans. Tongking comprises two regions: (1) the delta of the Song-Koi (Red river), which, beginning at Son-Tay and coalescing with the delta of the Thai-Binh, widens out into the low-lying and fertile plain within which are situated the principal cities. The delta is joined to upper Tongking by undulating country becoming more and more elevated inland and called sometimes Middle Tongking; (2) upper Tongking, a mountainous forest clad country, deeply dissected by the slot-valleys of the Taibinh, the Red River and their tributaries. The main geographical feature in the country is the Song-Koi, which, taking its rise in Yun-nan at more than 2,000 metres above sea level, enters Tongking at Lao-Kay, and flows thence in a south-easterly direction to the Gulf of Tongking. It was this river which mainly, in the first instance, attracted the French to Tongking, as it was believed that, forming the shortest route by water to Yun-nan, it would prove to be the most convenient and expeditious means of transporting the tin, copper, silver and gold which are known to abound there. This belief has proved fallacious because the upper course of the stream is constantly impeded by rapids, the lowest being about thirty miles above Hung-Hoa Beyond Lao-Kay navigation is impracticable during the dry season, and at all other times of the year goods have to be there transferred into light junks. Near Son-Tay the Song-Koi receives the waters of the Song-Bo (Black river) and the Song-Ka (Clear river), and from that point divides into a network of waterways which empty themselves by countless outlets into the sea The Song-Cau rises in north-eastern Tongking and below the town of Sept Pagodes, where it is joined by the Song-Thuong to form the Thai-Binh, divides into numerous branches, communicating with the Song-Koi by the Canal des Rapides and the Canal des Bambous

The coast line of Tongking from Mon-Kay on the Chinese frontier to Thanh-Hoa, near that of Annam, has a length of 375 m From Mon-Kay as far as the estuary of the Song-Koi it is broken, rugged and fringed with islands and rocky islets The bay of Tien-Hien, to the south of which lies the island of Ke-Bao, and the picturesque bay of Along, are the chief indentations. Beyond the island of Cac-Ba, south of the Bay of Along, the coast is low, flat and marshy.

Although under the monsoon régime, the climate of Tongking is less trying to Europeans than that of the rest of French Indo-China. During the hot season the temperature ranges between 82° and 100° F, but from October to May the weather is cool. The country is subject to typhoons in August and September.

In the wooded regions of the mountains the tiger, elephant and panther are found, and wild buffalo, deer and monkeys are common. The delta is the home of many varieties of aquatic birds. Tea, cardamom and mulberry grow wild, and in general the flora approximate to that of southern China.

The Annamese (*see* ANNAM), who form the bulk of the population of Tongking, are of a somewhat better physique than that of the other Indochinese. Savage tribes inhabit the northern districts—the Muongs the mountains bordering the Black river, the Thôs the regions bordering the Clear river and the Thai-Binh The Muongs are bigger and stronger than the Annamese They have square foreheads, large faces and prominent cheek-bones, and their eyes are often almost straight.

Rice, which in some places furnishes two crops annually, is the most important product of the delta, and the exports of the latter were valued at 149,000,000 francs in 1926. Elsewhere there are plantations of coffee, tobacco, cotton, jute, sugar-cane, etc. The cultivation of silkworms is of growing importance. (Export of raw silk 79,400 kg in 1926.)

Gold, copper, tin, lead and other metals are found in the higher regions of Tongking. There is a large output of coal from Hon-Gay on the bay of Along (Output [1925] 1,363,000 metric tons) The production of phosphates reaches 15,294 tons.

Hanoi, Hai-Phong and Nam-Dinh carry on cotton-spinning, and Hanoi and Nam-Dinh are well known for the manufacture of carved and inlaid furniture The natives are skilful at enamelling and the chasing and ornamentation of gold and other metals The manufacture of paper from the fibrous bark of the paper-tree is a wide-spread industry and there are numerous distilleries of rice-spirit.

In 1926 the imports were valued at 1,700,758,000 francs, while the exports did not exceed 1,316,401,000 francs in value

The transit trade via Tongking between Hongkong and Yun-nan is entirely in the hands of Chinese houses, the tin of the Yun-nan mines and cotton yarns from Hongkong constituting its most important elements. The waterways of the delta are lined with embankments, the causeways along which form the chief means of land communication of the region. (For railways, *see* INDO-CHINA, FRENCH.)

The protectorate of Tongking approaches nearer to direct

administration than that of Annam, where the conditions of the protectorate are more closely observed. Till 1897 the emperor of Annam was represented in Tongking by a viceroy (*kinh-luoc*), but now the native officials are appointed by and are directly under the control of the resident-superior, who resides at Hanoi (pop. 103,235), the capital of Indo-China, presides over the protectorate council, and is the chief territorial representative of France. Tongking is divided into nineteen provinces, in each of which there is a resident or a vice-resident. In each province there is a council of native "notables," elected by natives and occupied with the discussion of the provincial budget and public works. There is also a deliberative council of natives for the whole of Tongking. The provincial administration, local government and educational system are analogous to those of Annam (*q.v.*). Two chambers of the court of appeal of Indo-China and a criminal court sit at Hanoi; there are tribunals of first instance and tribunals of commerce at Hanoi and Hai-Phong. When both parties to a suit are Annamese, it comes within the jurisdiction of the *An-Sat* or native judge of the province.

The local budget for 1927 balanced at 18,017,180 piastres. *See* also INDO-CHINA, FRENCH and ANNAM.

HISTORY

For the early history of Tongking, *see* ANNAM and INDO-CHINA, FRENCH. Tongking was loosely united to Annam until 1801, when Gia-long, king of Annam, brought it definitely under his sway. Having, by the treaty of 1862 and the annexation of Cochin China, firmly established themselves in Annamese territory, the French began to turn their attention to Tongking, attracted by the reported richness of its mineral wealth The invasion of northern Tongking by the disbanded followers of the Taiping rebels offered a pretext for action Hostilities were checked for a time by the Franco-Prussian War (1870–71), but in 1873 Garnier attacked Hanoi as a protest against the hindrances offered to Dupuis, a trader with military stores for Yunnan, and carried the citadel by assault He then sent to Saigon for reinforcements and meanwhile attacked the five other important fortresses in the delta (Hung-Yen, Phu-Ly, Hai-Duong, Ninh-Binh, and Nam-Dinh), and captured them all This provoked the Tongkingese to call in the help of Lu-Vinh-Phuoc, the leader of the "Black Flags" (bands of Chinese rebels infesting the mountainous region of Tongking), who at once marched with a large force to the scene of action. Within a few days he had recaptured several villages near Hanoi, and so threatening did his attitude appear that Garnier, who had hurried back after capturing Nam-Dinh, made a sortie from the citadel, a move resulting in his death and that of his second in command

Meanwhile the news of Garnier's hostilities had alarmed the governor of Saigon, who, wishing to avoid war, sent Philastre, an inspector of native affairs, to offer apologies to the king of Annam. When, however, Philastre heard of Garnier's death, he took command of the French forces, and at once ordered the evacuation of Nam-Dinh, Ninh-Binh and Hai-Duong—a measure which resulted in a general massacre of native converts in the area. In pursuance of the same policy Philastre made a convention with the authorities (March 1874) by which he bound his countrymen to withdraw from the occupation of the country, retaining only the right to trade on the Song-Koi and at Hanoi and Hai-Phong. For a time affairs remained in *statu quo,* but in 1882 Le Myre de Villers, the governor of Cochin-China, sent Henri Rivière with a small force to open up the route to Yünnan by the Song-Koi. With a curious similarity the events of Garnier's campaign were repeated. Finding the authorities intractable, Rivière stormed and carried the citadel of Hanoi, with very slight loss, recaptured Nam-Dinh, Hai-Duong, and other towns in the delta, and then, like Garnier, fell a victim to his own impetuosity (May 1883).

In the meantime the Annamese court had been seeking to enlist the help of the Chinese in their contest with the French. The tie which bound the tributary nation to the sovereign state had never been entirely broken, and the present seemed an admirable opportunity for acknowledging the fact.

The king, therefore, despatched in 1880 a special embassy to Peking, loaded with unusually costly offerings and bearing a letter as from an acknowledged tributary which the emperor afterwards ordered to be published in the *Peking Gazette.* Rivière's death and the defeat of his troops left France in extreme difficulty, and M. Ferry, who had become French premier in 1883, decided on a vigorous policy. Hanoi was still besieged by the "Black Flags" and the outlying garrisons had mostly to be withdrawn; reinforcements under Admiral Courbet and General Bouet could barely keep the native forces at bay, and only in the lower delta did the French make headway, seizing Hai-Duong and Phu-Binh almost without a casualty. Dr. Harmand, commissary-general, proceeded with Courbet and a naval force to the Hué river. After a feeble defence Hué city was taken and a treaty concluded with the king (Aug 1883), in which the French protectorate was fully recognized, the king further binding himself to recall the Annamese troops serving in Tongking.

Though this treaty was exacted from Annam under pressure, the French lost no time in carrying out that part of it which gave them the authority to protect Tongking, and Bouet again advanced in the direction of Son-Tay But again the resistance he met with compelled him to retreat, after capturing the fortified post of Palan. Meanwhile, on the determination to attack Son-Tay becoming known in Paris, the Chinese ambassador warned the ministry that, since Chinese troops formed part of the garrison, he should consider it as tantamount to a declaration of war But his protest met with no consideration On the arrival of reinforcements an advance was again made, and on Dec. 16, 1883, after some desperate fighting, Son-Tay fell

During 1884 the French made themselves masters of the lower delta Throughout the campaign Chinese regulars fought against the French, who thus found themselves involved in war with China. In May 1884 M Fournier, the French consul at Tientsin, signed, with Li Hung Chang, a memorandum by which the Chinese plenipotentiary agreed that the Chinese troops should immediately evacuate northern Tongking A second treaty was signed at Hué confirming the French protectorate over Annam and Tongking, but hostilities did not cease A misunderstanding over the date of the Chinese evacuation led to Col Dugenne being despatched to occupy Lang-Son. The expedition was badly managed and 25m. from their objective the French entered an irregular engagement with the Chinese forces and were routed. An expedition, led by Colonel Donnier, against the Chinese garrison at Chu, about 10m south-east from Lang-kep, was completely successful; and in a battle near Chu the Chinese were defeated

In Jan 1885 large reinforcements arrived and Brière de l'Isle, who had succeeded Millot as commander-in-chief, ordered an advance towards Lang-Son. The difficulties of transport greatly impeded his movements; still, the expedition was successful. On Feb. 6 three forts at Dong-Song, with large supplies of stores and ammunition, fell into the hands of the French. Three days' heavy fighting made them masters of a defile on the road, and on the 13th Lang-Son was taken, the garrison having evacuated the town just before the entrance of the conquerors General Négrier, who commanded a division under Brière de l'Isle, pressed on in pursuit to Ki-Hea, and even captured the frontier town of Cua-Ai. But Brière de l'Isle had to hurry back to the relief of Tuyen-Kwan, which was doggedly resisting the attacks of an overwhelming Chinese force, and Négrier was left in command at Lang-Son. The withdrawal of Brière de l'Isle's division gave the Chinese greater confidence, and, though for a time Négrier was able to hold his own, on March 22 and 23 he sustained a severe check between Lang-Son and That-Ke, which was finally converted into a complete rout. Brière de l'Isle reached Tuyen-Kwan, the garrison of which was commanded by Colonel Dominé, on March 3 and effected its relief. The disaster at Lang-Son caused the downfall of the Ferry ministry (March 30). Shortly afterwards Sir Robert Hart succeeded in negotiating peace with China. By the terms agreed on at Tientsin (June 1885), it was stipulated that France was to take Tongking and Annam under its protection and to evacuate Formosa and the Pescadores. (For further history, *see* INDO-CHINA.)

TONGUE. Anatomically the tongue is divided into a main part, a base toward the pharynx, a dorsum or upper surface, a root by which it is attached to the hyoid bone and floor of the mouth, a tip which is free and an inferior free surface in contact with the front part of the floor of the mouth and with the lower incisor teeth. The dorsum is covered by stratified squamous epithelium, and, when at rest, is convex both anteroposteriorly and transversely; it is thickly studded with papillae, of which four kinds are recognized

Filiform papillae are minute conical projections covering the whole of the dorsum as well as the tip and borders of the tongue They are very numerous and contain a short core of subepithelial mucous membrane covered by a thick coating of epithelial cells, which coating may divide at its tip into a number of thread-like processes

Fungiform papillae are less numerous than the last, and somewhat resemble "button mushrooms", they generally contain special taste buds

Circumvallate papillae are usually from seven to ten in number and are arranged in the form of a V, the apex of which points down the throat They lie quite at the back of the upper surface of the tongue and each consists of a little flat central mound surrounded by a deep moat, the outer wall of which is slightly raised above the surface, and it is to this that the papillae owe their name Both sides of the moat have taste buds embedded in them, while into the bottom small serous glands open

Foliate papillae are only vestigial in man and consist of a series of vertical ridges occupying a small oval area on each side of the tongue near its base and just in front of the attachment of the anterior pillars of the fauces (*See* PHARYNX)

The posterior surface or base of the tongue forms part of the anterior wall of the pharynx and has a different appearance from that of the dorsum On it are found numerous circular or oval elevations of the mucous membrane caused by lymphoid tissue (lymphoid follicles), on the summit of the most of which is a mucous crypt or depression The division between the superior or oral surface of the tongue and the posterior or pharyngeal is sharply marked by a V-shaped shallow groove called the *sulcus terminalis* which lies just behind and parallel to the V-shaped row of circumvallate papillae At the apex of this V is a small blind pit, the *foramen caecum*

At the lower part of the pharyngeal surface three folds of mucous membrane, called *glosso-epiglottic folds,* run backward, the middle one passes to the centre of the front of the epiglottis, while the two lateral ones pass backward and outward to the fossa of the tonsil

On the inferior free surface of the tongue there is a median fold of mucous membrane called the *fraenum linguae*, which is attached below to the floor of the mouth On each side of this the blue outlines of the ranine veins are seen, while close to these a little fold on each side, known as a *plica fimbriata,* is often found It must not, however, be confused with the plica sublingualis described in the article MOUTH AND SALIVARY GLANDS.

The substance of the tongue is composed almost entirely of striped muscle fibres which run in different directions. Some of these bundles, such as the *superficial, deep, transverse* and *oblique linguales* are confined to the tongue and are spoken of as intrinsic muscles. Other muscles, such as the hyo-glossus, stylo-glossus, etc come from elsewhere and are extrinsic, these are noticed under the head of MUSCULAR SYSTEM The arteries of the tongue are derived from the lingual, a branch of the external carotid (*see* ARTERIES), while the veins from the tongue return the blood, by one or more veins on each side, into the internal jugular vein (*see* VEINS).

The nerves to the tongue are the (1) *lingual* or gustatory, a branch of the fifth (*see* NERVES: *Cranial*) which supplies the anterior two-thirds with ordinary sensation and also, by means of the chorda tympani which is bound up with it, with taste sensation; (2) the glossopharyngeal which supplies the circumvallate papillae and posterior third of the tongue with taste and ordinary sensation; (3) a few twigs of the superior laryngeal branch of the vagus to the pharyngeal surface of the tongue; and (4) the hypoglossal which is the motor nerve to the muscles

Embryology.—The mucous membrane covering the second and third visceral arches fuses to form the furcula (*see* RESPIRATORY SYSTEM) Just in front of this a rounded eminence appears at an early date in the ventral wall of the pharynx to form the *tuberculum impar* which is separated from the furcula by the depression known as the *sinus arcuatus* This tuberculum impar gradually grows to form the central part of the tongue in front of the foramen caecum, while the anterior part of the organ is derived from two lateral swellings which appear in the floor of the mouth and surround the tuberculum impar antero-laterally The posterior third, or pharyngeal part, is developed from the anterior part of the furcula in the middle line, that is to say from the third visceral arch The sinus arcuatus becomes gradually shallower as these two parts of the tongue grow together and eventually is indicated by the *sulcus terminalis,* in the mid line, however, the isthmus of the thyroid grows down from it, forming the *thyroglossal duct* the remains of which are seen in the foramen caecum (*see* DUCTLESS GLANDS) It will be seen that the tongue is developed in connection with the first, second and third visceral arches, and it is therefore to be expected that the fifth, seventh and ninth nerves which supply those arches would help to supply it, but the vagus from the fourth arch reaches it in addition, while the fact that most of the muscular substance of the tongue is supplied by the hypoglossal nerve is explained on the theory that some of the cervical skeletal musculature has grown cephalad into the tongue and has carried its nerve with it

Comparative Anatomy.—The tongue is present in fishes but it is an immovable swelling in the floor of the mouth and is practically devoid of muscles In the hag (*Myxine*) among the Cyclostomata, and pike (*Esox*) among the Teleostei, teeth are developed on the tongue In the Amphibia the tailed forms (Urodela) usually have tongues like fishes, though in the genus Spelerpes the organ is very free and can be protruded for a great distance In the majority of the Anura the tongue is usually attached close to the front of the floor of the mouth so that it can be flapped forward with great rapidity There are, however, two closely allied families of frogs (Xenopodidae and Pipidae) which form the order of Aglossa, because the tongue is suppressed

In the reptiles the tongue is generally very movable, though this is not the case in the Crocodilia and many of the Chelonia The forked tongues of snakes and many lizards and the highly specialized telescopic tongue of the chameleon are familiar objects

In birds the tongue is usually covered with horny epithelium and is poorly supplied with muscles When it is very protrusible, as in the woodpecker, the movement is due to the hyoid, with the base of the tongue attached, moving forward

In the Mammalia the tongue is always movable by means of well-developed extrinsic and intrinsic muscles, while papillae and glands are numerous The filiform papillae reach their maximum in the feline family of the Carnivora where they convert the tongue into a rasp by which bones can be licked clean of all flesh attached to them.

Foliate papillae are best seen in the rodents, and when they are well developed the circumvallate papillae are few, often only one on each side

In the lemurs an under tongue or *sub lingua* is found, which is probably represented by the *plicae fimbriatae* under the human tongue, and by some morphologists is regarded as the homologue of the whole tongue of the lower vertebrates, the greater part of the mammalian tongue being then looked upon as a new formation

Gegenbaur, *Vergleich Anat der Wirbelthiere* (Leipzig, 1901); A. Oppel, *Lehrb vergleich mikroskop Anat der Wirbelthiere,* Teil 3 (Jena, 1900), Parker and Haswell, *Text Book of Zoology* (London, 1897) (F G P.)

TONGUE, DISEASES OF. The most important disease of the tongue is cancer which may affect any part but is liable to occur at the sides, when the organ is irritated by a carious tooth or an ill-fitting denture. It shows itself as a hard raised ulcer and microscopically is a squamous cell carcinoma (*see* TUMOURS). The lymphatic glands in the neck and beneath the jaw are early affected by extension of the disease. At first the disease causes little more than discomfort and some pain in feeding but soon the extension leads to fixation and the jaws often cannot be separated more than to admit passage of a lead pencil between the teeth The secondary growths in the neck and beneath the jaw increase in size rapidly and may break down leading to a foul ulcer or to haemorrhage from invasion of one of the great blood vessels in the neighbourhood. The great salivation that accompanies cancer of the tongue is one of its greatest trials The natural duration of the disease from first observation to death is on an average little over a year Until recently the sole possible form of treatment was surgery consisting in removal of the tongue and of cervical glands in a single or a divided operation When the growth affects the anterior portion of the organ this operation meets with a fair amount of success but when the side or back of the tongue is affected the operation is serious and the results are poor so far as concerns prolonged duration of life. At the present time treatment by radium in the form of radium needles or minute "seeds" containing radium emanation is practised Sufficient time has not passed for dogmatic statement but the results appear to compare favourably with those of surgery. Whenever a carious tooth irritates the tongue the dentist's services should be sought Other diseases of the tongue of importance are syphilitic In leukoplakia the epidermis becomes thick and white in patches over the dorsum; the condition is of great importance since cancer is liable to begin in such leukoplakic patches The other syphilitic condition is gumma (*see* VENEREAL DISEASES), a condition difficult to diagnose from cancer except by the course it takes. As procrastination is fatal if the condition be cancer in reality, and a person from whom the tongue has been removed is not greatly inconvenienced thereby, the treatment should be based upon the more serious assumption

Hardly coming under the definition of diseases are those morbid states of the tongue met with in various disorders involving other parts of the body The appearances noted when the physician "looks at the tongue" vary according to the degree to which epithelial cells cover the papillae and the degree to which saliva is formed. In the white or plastered tongue of acute febrile disease the papillae are covered by a thick layer of proliferated epithelium in which are many micro-organisms, and the mouth is dry. If the fever continues and intensifies the coat peels off and a red, dry, denuded tongue results. If, on the contrary, improvement in the patient's condition is taking place the tongue begins to "clean" at the tip and edges, *i e*, secretion of saliva recommences and the white coat is removed by rubbing against the teeth and palate. The flabby, tooth-indented tongue of dyspepsia, the red, cracked tongue of diabetes, the tremulous tongue of alcoholism, the laterally displaced tongue indicating paralysis as in cerebral apoplexy are other examples of the information which examination of the tongue affords to the instructed eye (*see* Howship Dickinson, *The Tongue in Disease*, London, 1888).

So-called "thrush" (aphtha) occurs over the tongue and mouth of babies in poor condition, usually from faulty feeding; it is caused by the growth of yeast moulds in the superficial layers of the epithelium and is favoured by an acid reaction of the saliva and mucus in the mouth The treatment is rectification of the feeding and local application of a mixture of myrrh, borax and honey. Other abnormal conditions of the tongue occur such as small ulcerations in some cases of advanced pulmonary tuberculosis and inflammatory masses in actinomycosis (*q.v.*).

(W. S. L.-B.)

TONGUES, GIFT OF, a faculty of abnormal and inarticulate vocal utterance, under stress of religious excitement, which was widely developed in the early Christian circles, and has its parallels in other religions. It is also called Glossolalia (Gr γλῶσσα, tongue, λαλεῖν, speak). In the New Testament such experiences are recorded in Caesarea (Acts x 46), at Corinth (Acts xix. 6; 1 Cor. xii, xiv), Thessalonica (1 Thess. v. 19) Ephesus (Eph. v. 18), and universally (Mark xvi. 17), From the epistles of Paul, who thanked God that he spake with tongues more than all or any of his Corinthian converts, we can gather a just idea of how he regarded this gift and of what it really was.

Paul discriminates between the Spirit which during these paroxysms both talks and prays to God and the *nous* or understanding which informs a believer's psalm, teaching, revelation or prophesy, and renders them intelligible, edifying and profitable to the assembly. Accordingly Paul lays down rules which he regarded as embodying the Lord's commandment. A man "that speaketh in a tongue speaketh not unto men, but unto God; for no man understandeth"; and therefore it is expedient that he keep this gift for his private chamber and there pour out the mysteries. In church it is best that he should confine himself to prophesying, for that brings to others "edification and comfort and consolation" If, however, tongues must be heard in the public assembly, then let not more than three of the saints exhibit the gift, and they only in succession. Nor let them exhibit it at all, unless there is some one present who can interpret the tongues and tell the meeting what it all means. If the whole congregation be talking with tongues all at once, and an unbeliever or one with no experience of pneumatic gifts come in, what will he think, asks Paul Surely that "you are mad" So at Pentecost on the occasion of the first outpouring of the Spirit the saints were by the bystanders accused of being drunk (Acts ii. 15). In the church meeting, says Paul, "I had rather speak five words with my understanding, that I might instruct others also, than ten thousand words in a tongue."

Paul on the whole discouraged glossolaly. "Desire earnestly the greater gifts," he wrote to the Corinthians. The gift of tongues was suitable rather to children in the faith than to the mature. Tongues were, he felt, to cease whenever the perfect should come; and the believer who spoke with the tongues of men and of angels, if he had not love, was no better than the sounding brass and clanging cymbal of the noisy heathen mysteries It was clearly a gift productive of much disturbance in the Church (1 Cor xiv. 23). He would not, however, entirely forbid and quench it (1 Thess. v. 19), so long as decency was preserved.

It is not then surprising that we hear little of it after the apostolic age It faded away in the great Church, and probably Celsus was describing Montanist circles (though Origen assumed that they were ordinary believers) when he wrote (Origen, *Contra Celsum*, vii. 9) of the many Christians of no repute who at the least provocation, whether within or without their temples, threw themselves about like inspired persons; while others did the same in cities or among armies in order to collect alms.

Tertullian in the 3rd century testifies that glossolaly still went on in the Montanist Church which he had joined; for we must so interpret the following passage in his *De anima*, cap. ix. "There is among us at the present time a sister who is endowed with the charismatic gift of revelations, which she suffers through ecstasy in the spirit during the Sunday service in church. She converses with angels, sometimes even with the Lord, and both hears and sees mysteries." The magical papyri teem with strings of senseless and barbaric words which probably answer to what certain of the Fathers called the language of demons. It has been suggested that we here have recorded the utterances of glossolalists.

The attitude of Paul toward glossolaly among his converts strikingly resembles Plato's opinion as expressed in the *Timaeus*, p. 72, of the enthusiastic ecstasies of the ancient μάντις (soothsayer). The gift of tongues and of their interpretation was

not peculiar to the Christian Church, but was a repetition in it of a phase common in ancient religions. The very phrase γλώσσαις λαλεῖν, "to speak with tongues," was not invented by the New Testament writers, but borrowed from ordinary speech.

Virgil (*Aen.* vi. 46, 98) draws a life-like picture of the ancient prophetess "speaking with tongues" He depicts her quick changes of colour, her dishevelled hair, her panting breast, her apparent increase of stature as the god draws nigh and fills her with his divine afflatus. Then her voice loses its mortal's ring: "nec mortale sonans" The same morbid and abnormal trance utterances recur in Christian revivals in every age, *e g*, among the mendicant friars of the 13th century, among the Jansenists, the early Quakers, the converts of Wesley and Whitefield, the persecuted protestants of the Cevennes, the Irvingites, and the revivalists of Wales and America.

Oracular possession of the kind above described is also common among savages and people of lower culture; and Dr Tylor, in his *Primitive Culture*, ii. 14, gives examples of ecstatic utterance interpreted by the sane Thus in the Sandwich Islands the god Oro gave his oracles through a priest who "ceased to act or speak as a voluntary agent, but with his limbs convulsed, his features distorted and terrific, his eyes wild and strained, he would roll on the ground foaming at the mouth, and reveal the will of the god in shrill cries and sounds violent and indistinct, which the attending priests duly interpreted to the people"

See E B Tylor, *Primitive Culture;* H Weinel, *Die Wirkungen des Geistes und der Geister* (Freiburg, 1899); Shaftesbury's *Letter on Enthusiasm*, Mrs. Oliphant, *Life of Irving*, vol. ii, G. B Cutten, *Speaking with Tongues, Historically and Psychologically Considered* (1927) (the most complete existing survey of the subject). *See* also Thouless, *Introduction to the Psychology of Religion*, chap xi

TONIC SOL-FA. Tonic Sol-fa has as its leading principle the relationship of Sol-fa syllables to a key-note. The prefix "tonic" was used by John Curwen to distinguish his method from others. Curwen (1816–1880) developed his method from that of Miss Sarah Ann Glover (1785–1867) of Norwich, to whom he always acknowleged his indebtedness, but, seeing no probability of her system becoming popular (it was out of print), he announced a number of modifications (twenty-one are tabulated in his *Teacher's Manual*), which, with his remarkable pedagogical and organizing powers, established the "Tonic Sol-fa Method and Notation" as a national movement

What, then, is Tonic Sol-fa? It is a letter-notation, as distinguished from a staff-notation. The initials of seven old syllables are used They formed what was later called a "movable *do*" system, and Tonic Sol-fa follows this old practice. Guido d'Arezzo (995–1050) noticed that each line of a hymn to St. John began stepwise, forming his hexachord instead of the former Greek tetrachords, and he took the first syllable of each line of the hymn as a sound-name, thus ut, re, mi, fa, sol, la The last line of the hymn was Sancte Iohannes The initial letters, *si*, were added in the 16th century to represent the seventh of the modern major scale In the 17th century *do* (probably from Dominus) was substitued in most countries for *ut* In the 19th century in England *si* was changed to *te* to avoid confusion with the initial of *sol*, and the spelling of all the syllables was adapted to the English language, with the advantage of having an open vowel sound for every note. The higher octave was shown by a small figure on the right above the note (d^1), and the lower octave syllables had a figure below the note ($s_1 s_1$) at the right side as shown

Besides the signs for tune already given, a notation of time was adopted, and equal spacing represented duration pictorially. A vertical line (|) precedes the accent at the beginning of the bar (measure). A short perpendicular line (|) shows the middle or medium accent of common time (four-pulse measure). An accent mark if followed by an unfilled (un-syllabled) space indicates a rest. When a note follows the accent mark it occupies the time from that accent to the next. A long dash (—) after a note requires the sound to be continued through the next pulse or beat. A dot (full point) between two notes divides the pulse into equal parts (d.r). A dot before a continuation mark (short dash) indicates that the previous note is to be continued through half of that pulse. A comma is the sign for a quarter-pulse (d,r). A dot and comma placed together show that the preceding note is of ¾-pulse length, and the following note ¼-pulse length (d ,r). An inverted comma is placed after a note of one-third pulse length (d,r) A line placed below two or more notes signifies that the notes are to be sung to the single syllable or word underneath the notes (d r). A brace binds each line of the score, and a double bar shows the end of the music. A tune may be quoted which gives within one bar five signs for rhythm

Key A	m	m	, r	|d ,l_1	.— : l_1	d ‖
	Oft	in	the	stilly	night,	Ere ‖

The question of key arises At the beginning of the tune the pitch of it is indicated by the standard pitch-names (Key A, etc) Here comes the "enlightening fact" to a beginner A tune in Tonic Sol-fa notation has the same appearance (apart from octave marks) whether pitched high or low, it is recognized as the same tune In the song of Moore above, for example, the same syllables would be used whether sung at a pitch suitable to tenor or bass The Tonic Sol-faist, having a movable doh method, has not to use a fresh set of syllables with every change of pitch, in the "fixed doh" way.

In modulation (called transition) to a new key in the course of a tune, the Tonic Sol-faist finds a new signature at the point of change, and is thus prepared If a sharp key (passing from key F to key C is a remove sharp-wards) is imminent, the new tone (the sharp) is printed over the music (for example, A t) on the right of the key-name. If the tune passes flat-wards, the "distinguishing tone" is placed on the left of the key-name (fah in key F, for example, f F) If the transition involved four removes to the right (sharp-ward progressions) the distinguishing tones would be t m l r Four flat-ward removes would have as distinguishing tones at each remove, r s d f , read backwards The latest practice is to name the number of new tones above three by a figure, as B 4, for example In the minor key (mode) the key-note is *lah*, thus in A minor "Lah is A"

Besides having changes of key defined by fresh signature (a practice which is growing in staff notation printing), the Tonic Sol-faist is given a new syllable, forming a bridge-tone or double-name, of which, with practice, he thinks the first and sings the second, or as a beginner he will glide from one to the other, as m'lah, or as a barrister addresses m'lor In print, this is shown thus ^{m}l. Explanation of the treatment of minor keys cannot be pursued here, but the "minor mode" gives the Tonic Sol-faist no trouble.

A further detail is with regard to the inflected names adopted for "accidentals" (chromatics). Doh becomes, a semitone higher, de, and the long *e* sound also represents *re, fe, se, le* Depress *te* and it is named *taw*, printed *ta* Similarly down "the modulator" may be found *la, ma, ra* Characteristic of the minor mode are *ba* (pronounced bay) and *se*

First lessons in Tonic Sol-fa are begun with the aid of a chart of tune the modulator just named Its ladder-like appearance is a great aid to the beginner; it is the counterpart of the up-and-down picture of the staff notation The mental image of the modulator remains, it is the answer to the objection that Tonic Sol-fa is a dead-level picture Even before it is used, the learner hears "the sound before the sign." He learns the scale by "steps of the method," first *d*, *s* and *m*, second *r* and *t*, third *f* and *l*, fourth the whole scale and transition Such simple tools enable the ordinary teacher of an elementary school to get from small children amazing results in sight-singing Each scale tone when sung slowly is also found to have its own character or mental effect, and this is noticed in illustrating by familiar phrases of music, which, however, must not be pressed too far; *d* is firm, *s* martial, *m* mild, *r* prayerful (at high pitch, rousing), *t* leading upward, *f* leaning downward, *l* the mournful tone The method applies other devices for teaching effect: French time-names for rhythm; hand-signs which, dispensing with printed notes, enable the teacher to give exercises rapidly. The ear is trained from the first lesson.

The value of it all is greatest in the higher stages: harmony is clarified by the tonic principle; transposition of music

is easy; rhythm is analyzed and simplified by the time-names; and, in addition, Tonic Sol-fa is the best introduction to the staff notation. More and more, publishers find it worth while to print the Tonic Sol-fa notation along with the Staff. The facility and certainty of the Tonic Sol-faists have been admitted and praised by every conductor who has had experience of them. The story of the successful struggle to give this method a footing need not be told here The danger now is when people in authority, or capable musicians who learnt music easily, say that the notation is unnecessary, while passing compliments upon the method of teaching, and at the same time ignoring the need of giving children a good foundation in reading this notation. (J Gra)

TÖNISSON, JAAN (1868–), Estonian statesman, was the son of a farmer in the Viljandi district of Livonia After graduating in law at the University of Dorpat (Tartu) he was for some years in the judicial service of the Russian Imperial Government, but quitted it in 1896 to become editor of *Postimees* (*The Postilion*), the oldest Estonian daily newspaper in Dorpat Thenceforward he took an active part in the Estonian national movement. Tönisson took a line independent of both German and Russian political influences and concentrated upon work in the economic and cultural spheres. In the revolution of 1905 he was at the head of the Estonian moderate constitutional movement, which he likewise represented in the Russian Duma, where he attached himself to the Russian Cadet Party, and to the non-Russian element. With the other signatories to the Viborg Appeal, he was sentenced to three years' imprisonment and loss of political rights From 1917 onwards Tönisson, as leader of the Estonian People's Party, was a member of all the representative bodies of the Estonian people In the winter of the same year, after he had been expelled by the Bolsheviks, he carried through at Stockholm with the representatives of the Allied Powers the preliminaries of a *de facto* recognition of Estonia From 1919 to 1920 he was prime minister, and during his period of office peace was concluded with Russia In the second Riigikogo (parliament) he formed a democratic bloc of his own party, the Christian People's Party and the National Liberals and became president of the Chamber

TONK, an Indian state in the Rajputana agency It consists of six isolated tracts, some of which are under the Central India agency. Total area, 2,553 sq m ; total population (1921), 287,898. The chief, whose title is nawab, with a salute of 17 guns, is a Mohammedan of Afghan descent The founder of the family was Amir Khan, the notorious Pindari leader at the beginning of the 19th century, who received the present territory on submitting to the British in 1817 The town of Tonk is 60 m south from Jaipur, near the right bank of the river Banas Pop (1921), 30,374. It is surrounded by a wall, with a mud fort

There is another town in India called Tonk, or Tank, in Dera Ismail Khan district, North-West Frontier Province. It is the residence of a nawab, who was formerly semi-independent

TONKAWA, a tribe of south central Texas, usually considered as constituting a distinct linguistic stock, belonged to the Plains group of nomadic buffalo hunting Indians The natives lived in skin tepees, planted little or not at all and bore a reputation, probably deserved, for cannibalism They fought, at one time or another, most of their neighbours, from the Apache to the Caddo The original population of perhaps 1,500 has shrunk to a few dozen

TONNAGE, SHIPPING: *see* Shipping, Tonnage Terms

TONNAGE AND POUNDAGE. In England, customs duties anciently imposed upon exports and imports, the former being a duty upon all wines imported in addition to prisage and butlerage, the latter a duty imposed *ad valorem* at the rate of 1s. in the £ on all merchandise imported or exported. The duties were levied at first by agreement with merchants (poundage in 1302, tonnage in 1347), then granted by parliament in 1373, at first for a limited period only They were considered to be imposed for the defence of the realm. From the reign of Henry VI until that of James I. they were usually granted for life. They were not granted to Charles I., and in 1628 that king took the unconstitutional course of levying them on his own authority, a course denounced a few years later by 16 Car. I. c. 18 (1640), when the long parliament granted them for two months After the Restoration they were granted to Charles II. and his two successors for life. By acts of Anne and George I., the duties were made perpetual and mortgaged for the public debt. In 1787 they were finally abolished, and other modes of obtaining revenue substituted, by 27 Geo. III c. 13 (1787)

Poundage also signified a fee paid to an officer of a court for his services, *e.g* , to a sheriff's officer, who is entitled by 29 Eliz c 4 (1586–87) to a poundage of 1s. in the £ on an execution up to £100, and sixpence in the £ above that sum

TONNERRE, a town of north-central France, in the department of Yonne, 52 m S E. of Sens on the P.L.M. railway. Pop (1926) 3,867 Its ancient name of *Tornodorum* points to a Gallic or Gallo-Roman origin for Tonnerre In the 6th century it became the capital of the region of Tonnerrois and in the 10th century of a countship

It stands on a slope of the vine-clad hills on the left bank of the Armançon At the foot of the hill rises the spring of Fosse-Dionne, enclosed in a circular basin 49 ft in diameter The church of St. Pierre has a fine lateral portal of the Renaissance period to which the church, except the choir (1351), belongs The church of Notre-Dame is mainly Gothic, but the fine façade is Renaissance. The hospital itself was rebuilt in the 19th century The Renaissance Hôtel d'Uzès was built in the 16th century

TONOPAH, an unincorporated city of Nevada, U S A , 170 m S E of Reno, in the San Antonio mountains, at an altitude of 6,072 ft.; the county seat of Nye county It is served by the Tonopah and Goldfield railroad The population was 4,144 in 1920 Tonopah is a vast mining camp, which has produced over $100,000,000 worth of silver since the first strike was made in 1899 In 1928 development of a new bonanza field was under way

TONQUA BEAN. The Tonqua, Tonka or Tonquin bean, also called the coumara nut, is the seed of *Dipterix odorata*, a leguminous tree growing to a height of 80 ft , native of tropical South America The drupe-like pod contains a single seed possessed of a fine sweet "new-mown hay" odour, due to the presence of coumarin (*q v*) Tonqua beans are used in perfumery

TÖNSBERG, a seaport of Norway, in Jarlsberg-Laurvik *amt* (county), situated on a bay on the south coast, near the entrance to Oslo Fjord, 72 m S by W of Oslo on the Skien railway Pop. (1927), 11,969 It is one of the most ancient towns in Norway, declined in importance after the middle ages, but is now a rapidly growing industrial town and the headquarters of a sealing and whaling fleet It has refineries for preparing whale and seal oil and saw-mills, and exports whale oil, pitch and butter. The harbour is frozen in winter but a channel is kept open

TONSILLITIS, acute inflammation of the tonsils (*see* Lymphatic System) due to their invasion by infective micro-organisms. Sometimes an attack follows on exposure to sewer gas, and it is common in house surgeons, nurses and others who have to spend most of their time in a hospital.

Tonsillitis is frequently associated with acute rheumatism (*q.v.*) and it is thought that the tonsils are often the portal whereby the streptococci causing rheumatism gain access to the body A similar view obtains with regard to the sore throat in scarlet fever. Acute tonsillitis may run on to the formation of abscess (quinsy) Tonsillitis may begin with a feeling of chilliness or an attack of shivering Then come on swelling in the throat, pain, tenderness and difficulty in swallowing, pain about the ear and jaw, and swelling of the glands in the neck. The temperature is raised, breath offensive and the tongue thickly coated. There may be yellow spots of inspissated mucus in the tonsillar crypts but these differ from the "false membrane" of diphtheria in that they can be easily brushed off by a swab, though often a true diagnosis can only be made bacteriologically The most trustworthy drugs are salicylic acid, iron and quinine. If abscess threatens, a slender-bladed knife should be thrust from before backward deeply into the swollen mass. And if, as most likely happens, matter then escapes, the patient's distress speedily ends.

Chronic tonsillitis is often associated with adenoids (*q.v.*) in children. It leads to enlargement of the tonsils which may meet

across the middle line of the throat. The lymphoid tissue of which the tonsil is composed is one of the body's lines of defence against invasion by infective micro-organisms, but these enlarged tonsils are abnormal in structure and not only fail as defensive mechanisms but also interfere seriously with the general health. Often, therefore, it becomes necessary to remove them surgically. Formerly the projecting mass was simply cut off but now the general procedure is enucleation of the entire tonsil.

TONSURE, a religious observance in the Roman Catholic and Orthodox Eastern Churches, consisting of the shaving or cutting of part of the hair of the head as a sign of dedication to special service The reception of the tonsure in these churches is the initial ceremony which marks admission to orders and to clerical rights and privileges. It is administered by the bishop with an appropriate ritual Candidates for the rite must have been confirmed, be adequately instructed in the elements of the Christian faith, and be able to read and write. Those who have received it are bound (unless in exceptional circumstances) to renew the mark, consisting of a bare circle on the crown of the head, at least once a month, otherwise they forfeit the privileges it carries. The practice is not a primitive one, Tertullian simply advises Christians to avoid vanity in dressing their hair, and Jerome deprecates both long and closely cropped hair. According to Prudentius (Περιστ. xiii 30) it was customary for the hair to be cut short at ordination Paulinus of Nola (*c.* 490) alludes to the tonsure as in use among the (Western) monks, from them the practice quickly spread to the clergy For Gaul about the year 500 we have the testimony of Sidonius Apollinaris (iv. 13), who says that Germanicus the bishop had his hair cut "in rotae speciem"

The earliest instance of an ecclesiastical precept on the subject occurs in can 41 of the Council of Toledo (A D 633): "omnes clerici, detonso superius capite toto, inferius solam circuli coronam relinquant." Can 33 of the Quinisext council (692) requires even singers and readers to be tonsured Since the 8th century three tonsures have been more or less in use, known respectively as the Roman, the Greek and the Celtic The first two are sometimes distinguished as the tonsure of Peter and the tonsure of Paul. The Roman or St Peter's tonsure prevailed in France, Spain and Italy. It consisted in shaving the whole head, leaving only a fringe of hair supposed to symbolize the crown of thorns Late in the middle ages this tonsure was lessened for the clergy, but retained for monks and friars In the Eastern or St Paul's tonsure the whole head was shaven, but when now practised in the Eastern Church this tonsure is held to be adequately shown when the hair is shorn close. In the Celtic tonsure (tonsure of St John, or, in contempt, tonsure of Simon Magus) all the hair in front of a line drawn over the top of the head from ear to ear was shaven (a fashion common among the Hindus). The question of the Roman or Celtic tonsure was one of the points in dispute in the early British Church, settled in favour of the Roman fashion at the Council of Whitby (664) The tonsure at first was never given separately, and even children when so dedicated were appointed readers, as no one could belong to the clerical state without at least a minor order From the 7th century, however, children were tonsured without ordination, and later on adults anxious to escape secular jurisdiction were often tonsured without ordination. Till the 10th century the tonsure could be given by priests or even by laymen, but its bestowal was gradually restricted to bishops and abbots.

TOOKE, JOHN HORNE (1736–1812), English politician and philologist, third son of John Horne, a poulterer in Newport Market, London, was born on June 25, 1736 He was educated at Westminster school, Eton, and St John's college, Cambridge. He had been entered at the Inner Temple, but his father wished him to take orders and he was ordained to a curacy at New Brentford in 1760. He travelled in France in 1765–67, where he met John Wilkes (*q.v*). In 1767 he returned and became Wilkes' most energetic and ingenious supporter. In 1771, however, he quarrelled violently with his leader, to the damage of their cause. Horne's supporters took the name of the Constitutional Society.

In 1773 he was placed beyond the reach of want by the gratitude of William Tooke, of Croydon, whose rights in an enclosure case he had protected by turning attention to his case

But Horne was now involved in serious trouble For signing the advertisement soliciting subscriptions for the relief of the relatives of the Americans "murdered by the king's troops at Lexington and Concord," he was tried at the Guildhall on July 4, 1777, before Lord Mansfield, found guilty, and committed to the King's Bench prison in St George's Fields, from which he only emerged after a year's durance, and after a loss in fines and costs amounting to £1,200. Soon after his deliverance he applied to be called to the bar, but his application was negatived on the ground that his orders in the Church were indelible Horne thereupon tried his fortune, but without success, on farming some land in Huntingdonshire. He also published two influential reforming pamphlets. *Facts Addressed to Landholders,* etc. (1780), and *A Letter on Parliamentary Reform* (1782)

On his return from Huntingdonshire he became once more a frequent guest at Mr. Tooke's house at Purley, and in 1782 assumed the name of Horne Tooke In 1786 Horne Tooke gave his philological treatise of Ἔπεα πτερόεντα (2 pts. 1786–1805), the sub-title of *The Diversions of Purley,* as a tribute to his friend.

Between 1782 and 1790 Tooke supported Pitt, and in the election for Westminster, in 1784, threw all his energies into opposition to Fox After the Westminster election of 1788 Tooke depicted the rival statesmen (Lord Chatham and Lord Holland, William Pitt and C. J Fox) in his pamphlet of *Two Pair of Portraits* At the general election of 1790 he was a candidate for Westminster, in opposition to Fox and Lord Hood, but was defeated; and, at a second trial in 1796, he was again at the bottom of the poll Meantime the excesses of the French revolution had provoked reaction in England, and the Tory ministry adopted a policy of repression. Horne Tooke was arrested early on the morning of May 16, 1794, and conveyed to the Tower His trial for high treason lasted for six days (Nov 17–22) and ended in his acquittal, the jury only taking eight minutes to settle their verdict Through the influence of the second Lord Camelford, he was returned to parliament in 1801 for the pocket borough of Old Sarum Efforts to secure his exclusion on the ground of his clerical orders failed, but an act was passed rendering all persons in holy orders ineligible, and he sat for that parliament only.

The last years of Tooke's life were spent in retirement in a house on the west side of Wimbledon Common, where he gave the Sunday parties, attended by Thurlow, Bentham, Coleridge, Paine and others, which became a legend He died on March 18, 1812

The *Life of Horne Tooke*, by Alexander Stephens, is written in an unattractive style and was the work of an admirer only admitted to his acquaintance at the close of his days The notice in the *Quarterly Review,* June 1812, of W. Hamilton Reid's compilation, is by J W. Ward, Lord Dudley The main facts of his life are set out by Mr. J E Thorold Rogers, in his *Historical Gleanings,* 2nd series. Many of Horne Tooke's wittiest sayings are preserved in the *Table Talk* of Samuel Rogers and S T Coleridge.

TOOKE, THOMAS (1774–1858), English economist, was born at St Petersburg on Feb 29, 1774 Entering a large Russian house in London at an early age, he acquired sound practical experience of commercial matters and became a recognized authority on finance and banking He was one of the earliest advocates of free trade and drew up the *Merchants' Petition* presented to the House of Commons by Alexander Baring, afterwards Lord Ashburton. He gave evidence before several parliamentary committees, notably the committee of 1821, on foreign trade, and those of 1832, 1840 and 1848 on the Bank Acts He was elected F.R S. in 1821. He died in London on Feb 26, 1858

Tooke is known for his *History of Prices and of the State of the Circulation during the Years 1793–1856* (6 vols, 1838–1857) In the first four volumes he treats (*a*) of the prices of corn, and the circumstances affecting prices; (*b*) the prices of produce other than corn, and (*c*) the state of the circulation The two final volumes, written in conjunction with W. Newmarch (*q.v.*), deal with railways, free trade, banking in Europe and the effects of new discoveries of gold

TOOL, an implement or appliance used by a worker in the treatment of the substances used in his handicraft, whether in

the preliminary operations of setting out and measuring the materials, in reducing his work to the required form by cutting or otherwise, in gauging it and testing its accuracy, or in duly securing it while thus being treated. (For the tools of prehistoric man *see* ARCHAEOLOGY: *Flint Implements;* and EGYPT.)

In beginning a survey of tools it is necessary to draw the distinction between hand and machine tools. The former class includes any tool which is held and operated by the unaided hands; *e.g.,* a chisel, plane or saw. Attach one of these to some piece of operating mechanism, and it, with the environment of which it is the central essential object, becomes a machine tool Simple examples are the common power-driven hack saw for metal, the small high-speed drill, and the wood-boring auger held in a frame and turned by a winch handle and bevel-gears. The difference between these and a big frame-saw cutting down a dozen boards simultaneously, or the immense machine boring the cylinders of an ocean liner, etc, is so vast that the relationship is hardly apparent. Often the tool itself is absolutely dwarfed by the machine, of which nevertheless it is the central object and around which the machine is designed and built. A milling machine weighing several tons will often be seen rotating a tool of but two or three dozen pounds' weight. Yet the machine is fitted with elaborate slides, self-acting movements and provision for taking up wear, and is worth some hundreds of pounds sterling, while the tool may not be worth two pounds. Such apparent anomalies are in constant evidence. This article is a survey of the principles that underlie the forms of tools. The subject of their embodiment in machine tools will be found and treated under MACHINE TOOLS, LATHES, PLANING MACHINES, MILLING MACHINES, SAWING MACHINES, WOOD-WORKING MACHINERY, etc

An analysis of the essential methods of operation gives a broad grouping as follows:

I The chisel group	Typified by	the chisel of the woodworker.
II. The shearing group	,, ,,	scissors.
III. The scrapers	,, ,,	cabinet-maker's scrape.
IV. The percussive and detrusive group	,, ,,	hammer and the punch.
V. The moulding group	,, ,,	trowel.

The first three are generally all regarded as cutting tools, notwithstanding that those in II and III. do not operate as wedges, and therefore are not true chisels; but many occupy a border-

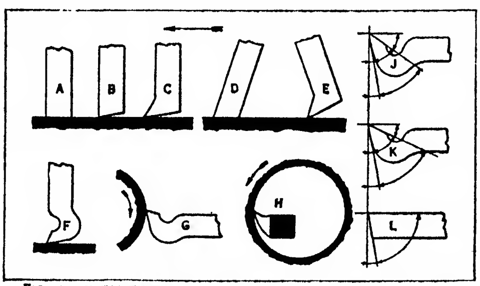

FIG. 1—METAL WORKING TOOLS (SEE TEXT FOR PARTICULARS)

line where the results obtained are practically those due to cutting, as in some of the shears, saws, milling cutters and grinding wheels.

CUTTING TOOLS

Keenness of edge, equivalent to a small degree of angle between the tool faces, would appear at first sight to be the prime element in cutting, as indeed it is in the case of a razor, or in that of a chisel for soft wood But that is not the prime condition in a tool for cutting iron or steel. Strength is of far greater importance, and to it some keenness of edge must be sacrificed. All cutting tools are wedges; but a razor or a chisel edge, included between angles of 15° or 20°, would be turned over at once if presented to iron or steel, for which angles of from 60° to 75° are required. Further, much greater rigidity is necessary in the latter, to resist spring and fracture. A workman can operate a turning tool by hand, even on heavy pieces of metal-work. Formerly all turning, no matter how large, was done by hand-operated tools, and after great muscular exertion a few pounds of metal might be removed in an hour. With a similarly formed tool, in a rigid guide or rest, driven by the power of ten or twenty men, it becomes possible to remove say a hundredweight of chips in an hour; or with

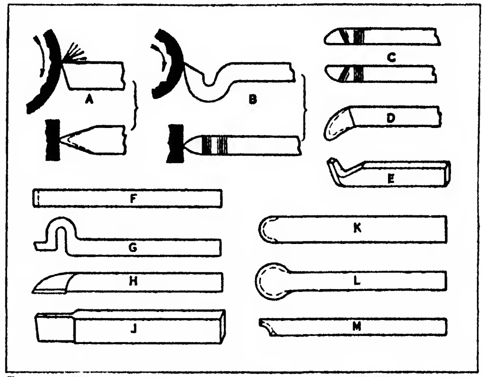

FIG 2—METAL-TURNING TOOLS (A) FOR SCRAPING BRASS, (B) FOR TURNING METALS, (C) RIGHT- AND LEFT-HAND TOOLS; (D) BETTER FORM OF SAME, (E) DIAMOND OR ANGULAR-EDGE, FOR CUTTING; (F) FINISHING TOOL; (G) SPRING FINISHING TOOL; (H) SIDE OR KNIFE TOOL; (J) PARTING OR CUTTING-OFF TOOL, (K, L) ROUND NOSE TOOLS, (M) RADIUS

a larger and more durable tool driven by the power of 40 or 60 horses, half a ton of chips may be removed in an hour

All machine tools of which the chisel is the type operate by cutting; *ie,* they act on the same principle and by the same essential method as the knife, razor or chisel, and not by that of the grindstone A single tool, however, may act as a cutting instrument at one time and as a scrape at another.

Clearly, in order that a tool shall cut, it must possess an incisive form In fig. 1, *A* might be thrust over the surface of the plate of metal, but no cutting action could take place. It would simply grind and polish the surface If it were formed like *B,* the grinding action would give place to scraping, by which some material would be removed. Many tools are formed thus, but there is still no incisive or knife-like action, and the tool is simply a scrape and not a cutting tool. But *C* is a cutting tool, possessing penetrative capacity If now *B* were tilted backwards as at *D,* it would at once become a cutting tool. But its bevelled face would rub and grind on the surface of the work, producing friction and heat, and interfering with the penetrative action of the cutting edge On the other hand, if *C* were tilted forwards as at *E* its action would approximate to that of a scrape for the time being But the high angle of the hinder bevelled face would not afford adequate support to the cutting edge, and the latter would therefore become worn off almost instantly, precisely as that of a razor or wood-working chisel would crumble away if operated on hard metal It is obvious therefore that the correct form for a cutting tool must depend upon a due balance being maintained between the angle of the front and of the bottom faces—"front" or "top rake," and "bottom rake" or "clearance"—considered in regard to their *method of presentation* to the work Since, too, all tools used in machines are held rigidly in one position, differing in this respect from hand-operated tools, it follows that a constant angle should be given to instruments which are used for operating on a given kind of metal or alloy. It does not matter whether a tool is driven in a lathe, or a planing machine, or a sharper or a slotter; whether it is cutting on external or internal surfaces, it is always maintained in a direction perpendicularly to the point of application as in fig. 1, *F, G, H,* planing, turning and boring respectively. It is consistent with reason and with fact

that the softer and more fibrous the metal, the keener must be the formation of the tool, and that, conversely, the harder and more crystalline the metal the more obtuse must be the cutting angles, as in the extremes of the razor and the tools for cutting iron and steel already instanced. The three figures *J, K, L* show tools suitably formed for wrought iron and mild steel, for cast iron and cast steel, and for brass respectively. Cast iron and cast

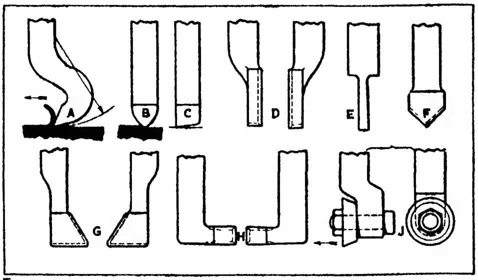

FIG 3 —PLANER TOOLS (A) CRANKED TO AVOID DIGGING INTO METAL. (B) FACE OF ROUGHING TOOL. (C) FACE OF FINISHING TOOL. (D) RIGHT- AND LEFT-HAND KNIFE OR SIDE TOOLS. (E) PARTING, CUTTING-OFF OR GROOVING TOOL. (F) V TOOL. (G) RIGHT- AND LEFT-HAND TOOLS FOR V-SLOTS. (H) SAME FOR T-SLOTS. (J) RADIUS TOOL IN HOLDER

steel could not be cut properly with the first, nor wrought iron and fibrous steel with the second, nor either with the third The angles given are those which accord best with general practice

The *angle of clearance*, or *relief*, fig 1 J, K & L, is an important detail of a cutting tool It is of greater importance than an exact angle of top rake, but, given some sufficient angle of clearance, its exact amount is not of much moment Neither need it be uniform for a given cutting edge It may vary from say 3° to 10°, or even 20°, and under good conditions little or no practical differences will result Actually it need never vary much from 5° to 7°. The object in giving a clearance angle is simply to prevent friction between

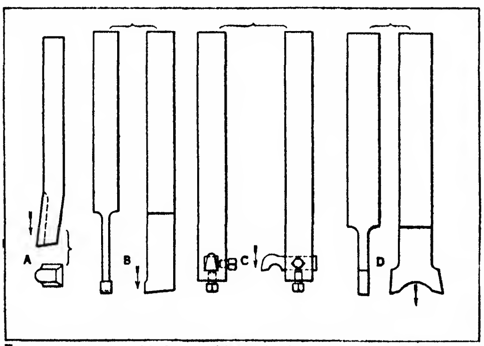

FIG. 4.—SLOTTER TOOLS. (A) COMMON ROUGHING. (B) PARTING-OFF OR GROOVING; (C) ROUGHING OR FINISHING TOOL IN HOLDER. (D) DOUBLE-EDGED FOR CUTTING OPPOSITE SIDES OF SLOT

the non-cutting face immediately adjacent to the edge and the surface of the work. The limit to this clearance is that at which insufficient support is afforded to the cutting edge.

The *front*, or *top rake*, *b* in fig. 1, is the angle or slope of the front, or top face, of the tool; it is varied mainly according as materials are crystalline or fibrous. In the turnings and cuttings taken off the more crystalline metals and alloys, the broken appearance of the chips is distinguished from the shavings removed from the fibrous materials. It indicates too that extra work is put on the tool in breaking up the chips, following immediately on their severance, and when the comminutions are very small they indicate insufficient top rake. This is a result that turners try to avoid when possible, or at least to minimize Now the greater the slope of the top rake the more easily will the cuttings come away, with the minimum of break in the crystalline materials and absolutely unbroken over lengths of many feet in the fibrous ones. The breaking up or the continuity of the cuttings, therefore affords an indication of the suitability of the amount of top rake to its work. However, compromise often has to be made between the ideal and the actual. The amount of top rake has to be limited in the harder metals and alloys in order

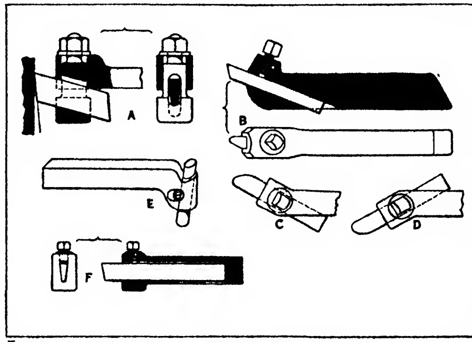

FIG. 5 —TOOL-HOLDERS (A) SWIVELLING HOLDER. (B) SQUARE STEEL HOLDER. (C, D) RIGHT- AND LEFT-HAND FORMS OF SAME. (E) ROUND STEEL HOLDER. (F) NARROW PARTING-OFF TOOL HOLDER

to secure a *strong tool angle*, without which tools would lack the endurance required to sustain them through several hours without regrinding.

The *tool angle*, *c*, is the angle included between top and bottom faces, and its amount, or thickness expressed in degrees, is a measure of the strength and endurance of any tool At extremes it varies from about 15° to 85° It is traceable in all kinds of tools, having very diverse forms

Tools of the Chisel Type.—The grouped illustrations (figs. 2 to 6) show some of the types, but it will be understood that each is varied in dimensions, angles and outlines to suit all the varied kinds of metals and alloys and conditions of operation For, as every tool has to be gripped in a holder of some kind, as a slide-rest, tool-box, turret, tool-holder, box, cross-slide, etc, this often determines the choice of some one form in preference to another A broad division is that into roughing and finishing tools Generally though not invariably the edge of the first is narrow, of the second broad, corresponding with the deep cutting and fine traverse of the first and the shallow cutting and broad traverse of the second The following are some of the principal forms The round-nosed roughing tool (fig 2) *B* is of straight-forward type, used for turning, planing and shaping As the correct tool angle can only occur on the middle plane of the tool, it is usual to employ cranked tools, *C, D, E*, right- and left-handed, for heavy and moderately heavy duty, the direction of the cranking corresponding with that in which the tool is required to traverse Tools for boring are cranked and many for planing (fig. 3). The slotting tools (fig. 4) embody the same principle, but their shanks are in line with the direction of cutting. Many roughing and

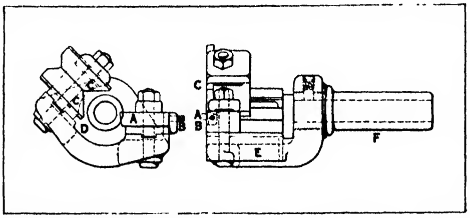
FIG 6 —CHISELS· (A) PARING. (B) SOCKET, HEAVY DUTY (C) COMMON CHIPPING; (D) NARROW CROSS-CUT OR CAPE. (E) COW-MOUTH; (F) STRAIGHT. (G) HOLLOW

finishing tools are of knife type *H* Finishing tools have broad edges, *F, G, H*. They occur in straightforward and right- and left-hand types These as a rule remove less than $\frac{1}{16}$ in. in depth, while the roughing tools may cut an inch or more into the metal

Solid Tools v. Tool-holders.—It will be observed that the foregoing are solid tools; that is, the cutting portion is forged from a solid bar of steel This is costly when the best tool steel is used,



BY COURTESY OF ALFRED HERBERT, LTD

FIG. 7 —BOX TOOL FOR TURRET LATHE (A) CUTTING TOOL, (B) SCREW FOR ADJUSTING RADIUS OF CUT, (C C) V-STEADIES, (D) DIAMETER OF WORK; (E) BODY OF HOLDER, (F) STEM

hence large numbers of tools comprise *points* only, which are gripped in permanent holders in which they interchange Tool steel usually ranges from about ½ in to 4 in square, most engineers' work is done with bars of from ½ in to 1½ in square It is in the smaller and medium sizes of tools that holders prove of most value Solid tools, varying from 2½ in to 4 in square, are used for the heaviest cutting done in the planing machine Tool-holders are not employed for very heavy work, because the heat generated would not get away fast enough from small tool points There are scores of holders, perhaps a dozen good approved types are in common use They are divisible into three great groups those in which the top rake of the tool point is embodied in the holder, and is constant, those in which the clearance is similarly embodied; and those in which neither is provided for, but in which the tool point is ground to any angle Charles Babbage designed the first tool-holder, and the essential type survives in several modern forms Fig 5 includes two forms of tool holder. In one *E* the tool is a bit of round steel set at an angle which gives front rake, and having the top end ground to an angle of top rake In

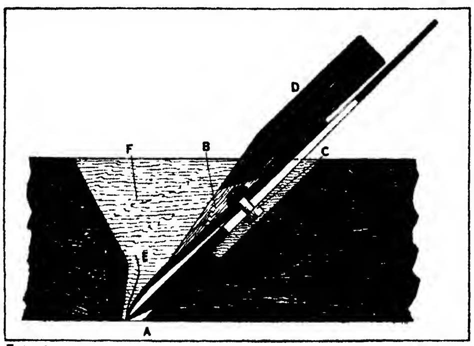


FIG 8 —SECTION THROUGH PLANE· (A) CUTTING IRON, (B) BACK IRON, (C) CLAMPING SCREW; (D) WEDGE, (E) BROKEN SHAVING, (F) MOUTH

the other *A* the tool has the section of a truncated wedge, set for constant top rake, or cutting angle, and having bottom rake or clearance angle ground This round tool is not applicable for all classes of work. It will turn plain work, and plane level faces, but will not turn or plane into corners or angles Hence the invention of the tool of V-section, and the swivel tool-holder The round tool-holders are made right- and left-handed, the swivel tool-holder has a universal movement The amount of projection of the round tool points is very limited, which impairs their utility when some overhanging of the tool is necessary The V-tools can be slid out in their holders to operate on faces and edges situated well inward from the end of the tool-holder.

Box Tools.—In one feature the box tools of the turret lathes resemble tool-holders. The small pieces of steel used for tool

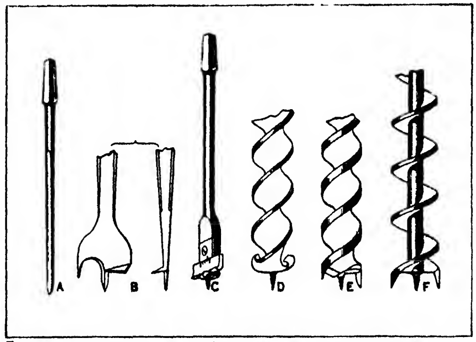

FIG 9 —WOOD BORING BITS (A) SPOON BIT, (B) CENTRE-BIT, (C) EXPANDING CENTRE-BIT, (D) GILPIN OR GEDGE AUGER, (E) JENNINGS AUGER, (F) IRWIN AUGER

points are gripped in the boxes, as in tool-holders, and all the advantages which are derived from this arrangement of separating the point from its holder are thus secured (fig 7) But in all other respects the two are dissimilar Two or three tool-holders

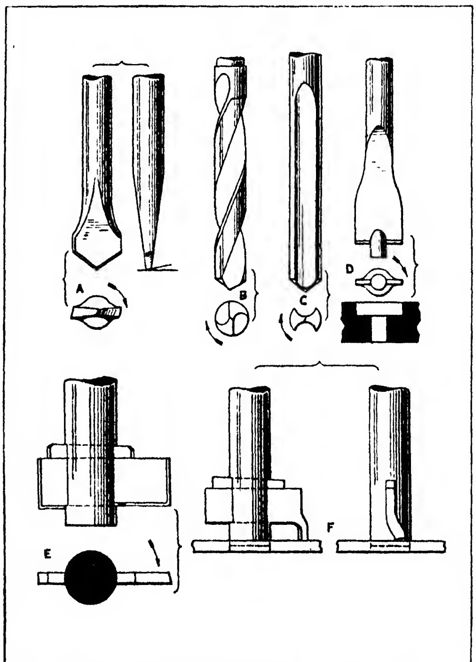

FIG 10 —METAL DRILLS: (A) FLAT, (B) TWIST, (C) STRAIGHT FLUTED, (D) PIN; (E) ARBORING; (F) TOOL FOR BORING SHEET METAL

of different sizes take all the tool points used in a lathe, but a new box has to be devised in the case of almost every new job, with the exception of those the principal formation of which is the turning down of plain bars. The explanation is that, instead of a single point, several are commonly carried in a box. As com-

plexity increases with the number of tools, new designs and dimensions of boxes become necessary, even though there may be family resemblances in groups. A result is that there is not, nor can there be, anything like finality in these designs. Turret work has become one of the most highly specialized departments of machine-shop practice, and the design of these boxes is already the work of specialists. More and more of the work of the common lathe is being constantly appropriated by the semi- and full-automatic machines, a result to which the magazine feeds for

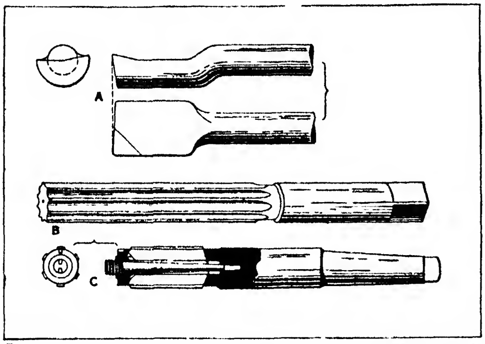

FIG 11.—(A) D-BIT, (B) SOLID REAMER, (C) ADJUSTABLE REAMER

castings and forgings that cannot pass through a hollow spindle have contributed to a great extent. A great deal of the efficiency of the box tools is due to the support which is afforded to the cutting edges in opposition to the stress of cutting. **V**-blocks are introduced in most cases as in fig. 7. In many tools a shearing operation takes place, by which the stress of cutting is lessened.

Planes.—Generally the tool angles of the chisel group lie between 15° and 25°. They include the chisels proper, and the gouges in numerous shapes and proportions, used by carpenters, cabinet-makers, turners, stone-masons, etc. These are mostly thrust by hand to their work, without any mechanical control. Other chisels are used percussively, as the stout mortise chisels, some of the gouges, the axes, adzes and stone-mason's tools.

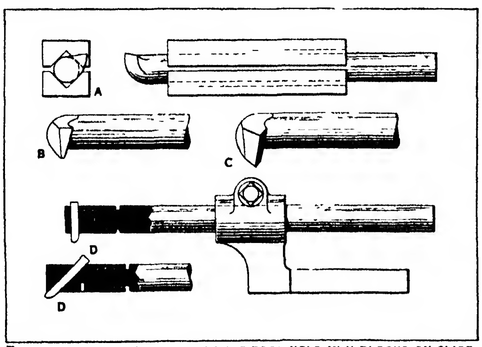

FIG 12.—BORING TOOLS (A) ROUND TOOL HELD IN V BLOCKS ON SLIDE-REST, (B, C) SQUARE AND V-POINTED, (D) BORING BAR WITH REMOVABLE CUTTERS

The large family of planes embody chisels coerced by the mechanical control of the wooden (fig. 8) or metal stock.

Drilling and Boring Tools.—Metal and timber are bored with equal facility; the tools (figs. 9 and 10) embody similar differences to the cutting tools already instanced for wood and metal. All the wood-working bits are true cutting tools, and their angles, if analysed, will be found not to differ much from those of the razor and common chisel. The drills for metal furnish examples both of scrapers and cutting tools. The common drill is only a scraper, but all the twist drills cut with good incisive action. An advantage possessed by all drills is that the cutting forces are balanced on each side of the centre of rotation. The same action is found in the best wood-boring bits—improved forms of the old centre-bit. But the balance is impaired if the lips are not absolutely symmetrical about the centre. This explains the

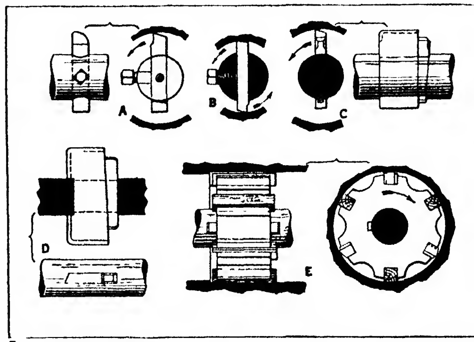

FIG 13.—SUPPORTED BORING TOOLS (A) SINGLE-ENDED CUTTER IN BORING BAR (B) SAME, DOUBLE-ENDED (C) FLAT SINGLE-ENDED FINISHING CUTTER, (D) SAME, DOUBLE-ENDED, (E) BORING HEAD WITH THREE CUTTER AND THREE STEADY BLOCKS

necessity for the substitution of machine grinding for hand grinding of the lips, and great developments of twist drill grinding machines. Allied to the drills are the **D**-bits, and the reamers (fig. 11). The first-named both initiate and finish a hole; the second are used only for smoothing and enlarging drilled holes, and for correcting holes which pass through adjacent castings or plates. The reamers remove only a mere film, and their action is that of scraping. The foregoing are examples of tools operated from one end and unsupported at the other, except in so far as they receive support within the work. One of the objectionable features of tools operated in this way is that they tend to "follow the hole," and if this is cored, or rough-drilled out of truth, there is risk of the boring tools following it to some extent at least. With the one exception of the **D**-bit there is no tool which can be relied on to take out a long bore with more than an approximation to concentricity throughout. Boring tools (fig. 12) held in the slide-rest will spring and bend and chatter, and unless the lathe is true, or careful compensation is made for its want of truth, they will bore bigger at one end than the other.

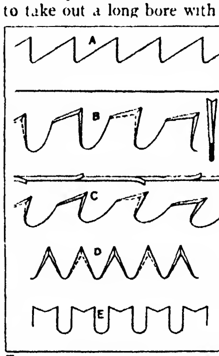

FIG 14.—SAW TEETH (A) BAND AND RIPPING, (B) CIRCULAR FOR HARD WOOD, (C) CIRCULAR FOR SOFT WOOD, (D) CROSS-CUT, (E) M-TEETH FOR CROSS-CUT

This brings us to the large class of boring tools which are supported at each end by being held in bars carried between centres. There are two main varieties: in one the cutters are fixed directly in the bar (fig. 13, *A* to *D*), in the other in a head fitted on the bar (fig. 13, *E*), hence termed a "boring head." As lathe heads are fixed, the traverse cannot be imparted to the bars as in boring machines. The boring heads can be traversed, or the work can be traversed by the mechanism of the lathe saddle. The latter must be done when cutters are fixed in bars. A great deal of difference exists in the details of the fittings both of bars and heads, but they are not so arbitrary as they might seem at first sight. The principal differences are those due to the number of cutters used, their shapes, and their method of fastening. Bars receiving their cutters direct include one, two or four, cutting on opposite sides, and

therefore balanced Four give better balance than two

Saws.—The saws are a natural connecting link between the chisels and the milling cutters. Saws are used for wood, metal and stone. Slabs of steel several inches in thickness are sawn

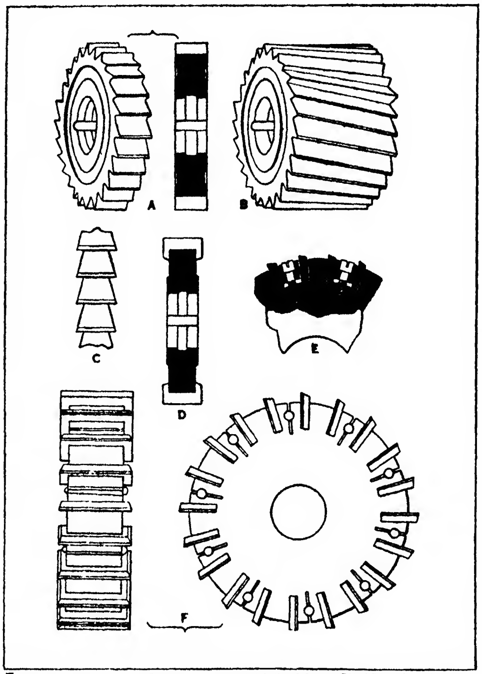

FIG. 15.—MILLING CUTTERS. (A) NARROW EDGE WITH STRAIGHT TEETH; (B) WIDE EDGE WITH SPIRAL TEETH. (C) TEETH ON FACE AND EDGES, (D) CUTTER WITH TEETH LIKE C. (E) FLAT TEETH, (F) INSERTED TOOTH

through as readily as. though more slowly than, timber planks. Circular and band saws are common in the smithy and the boiler and machine shops for cutting off bars, forgings and rolled sections. But the tooth shapes are not those used for timber, nor is the cutting speed the same In the individual saw-teeth both cutting and scraping actions are illustrated (fig 14) Saws which cut timber continuously with the grain, as rip, hand, band, circular, have incisive teeth, for though many are destitute of front rake, the method of sharpening at an angle imparts a true shearing cut. But all cross-cutting teeth scrape only, the teeth being either of triangular or of M-form, variously modified. Teeth for metal cutting also act strictly by scraping The pitching of the teeth is related to the nature of the material and the direction of cutting. It is coarser for timber than for metal, coarser for ripping or sawing with the grain than for cross cutting, coarser for soft than for hard woods The *setting* of teeth, or the bending over to right and left, by which the clearance is provided for the blade of the saw, is subject to similar variations. It is greatest for soft woods and least for metals, where in fact the clearance is often secured without set, by thinning the blade backwards.

Milling Cutters.—Between a circular saw for cutting metal and a thin milling cutter there is no essential difference. Increase the thickness as if to produce a very wide saw, and the essential plain edge milling cutter for metal results. In its simplest form the milling cutter is a cylinder with teeth lying across its periphery, or parallel with its axis—the *edge mill* (fig. 15), or else a disk with teeth radiating on its face, or at right angles with its axis—the *end mill* (fig. 16). Each is used indifferently for producing flat faces and edges, and for cutting grooves which are rectangular in cross-section

When more than about an inch in width, surfacing cylindrical cutters are formed with spiral teeth (fig. 15, B), a device which is

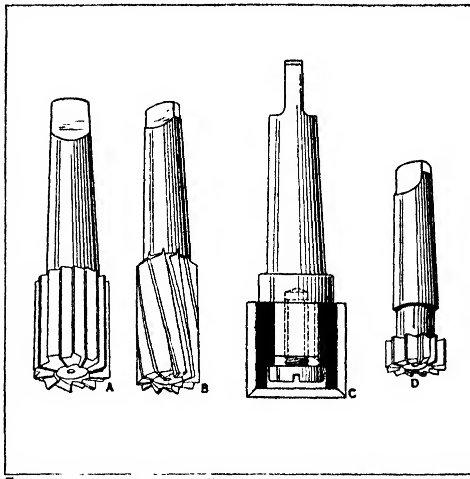

FIG. 16—END MILLS (A) WITH STRAIGHT TEETH, (B) WITH SPIRAL TEETH, (C) HOLDING SHELL CUTTER ON ARBOR WITH SCREW AND KEY, (D) T-SLOT CUTTER

essential to sweetness of operation, the action being that of shearing These have their teeth cut on universal machines, using the dividing and spiral head and suitable change wheels, and after hardening they are sharpened on universal grinders When cutters

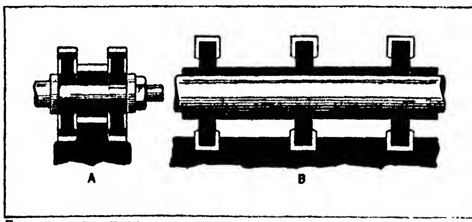

FIG 17—(A) STRADDLE MILL, (B) SET OF THREE MILLS FOR CUTTING GROOVES

exceed about 6 in in length the difficulties of hardening and grinding render the "gang" arrangement more suitable Thus, two, three or more similar edge mills are set end to end on an arbor, with the spiral teeth running in reverse directions, giving a broad face

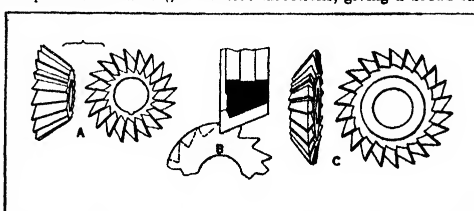

FIG. 18—ANGULAR MILLS (A) SINGLE SLOPE CUTTER: (B) CUTTER WITH SINGLE SLOPE PRODUCING TEETH IN ANOTHER CUTTER, (C) DOUBLE SLOPE MILL WITH UNEQUAL ANGLES

with balanced endlong cutting forces From these are built up the numerous gang mills, comprising plane faces at right angles with each other, of which the straddle mills are the best known (fig. 17, A). A common element in these combinations is the key seat

type B having teeth on the periphery and on both faces as in fig 15, C, D. In a single cutter of the face type, but having teeth on back and edge also, T-slots are readily milled (fig. 16, D).

When angles, curves and profile sections are introduced, the capacity of the milling cutter is infinitely increased. The making of the cutters is also more difficult. Angular cutters (fig. 18) are used for producing the teeth of the mills themselves, for shaping the teeth of ratchet wheels, and, in combination with straight cutters in gangs, for angular sections. With curves, or angles and curves in combination, taps, reamers and drills can be fluted or grooved, the teeth of wheels shaped, and in fact any outlines imparted (fig 19)

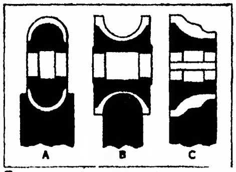

FIG 19 —CUTTERS (A) CONVEX, (B) CONCAVE; (C) PROFILE

One of the greatest advances in the practice of milling was that of making backed-off cutters The sectional shape behind the tooth face is continued identical in form with the profile of the edge, the outline being carried back as a curve equal in radius to that of the cutting edge (fig. 20) The result is that the cutter may be sharpened on the front faces of the teeth without interfering with the shape which will be milled, because the periphery is always constant in outline After repeated sharpenings the teeth would assume the form indicated by the shaded portion on two of the teeth The limit of grinding is reached when the tooth becomes too thin and weak to stand up to its work.

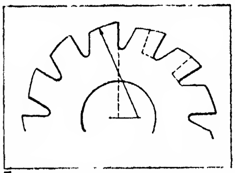

FIG 20 — RELIEVED TEETH OF MILLING CUTTER

Scrapes and Files.—The tools which operate by scraping (fig 21) include many of the broad finishing tools of the turner in wood and metal (*cf* fig 2), and the scrape of the wood worker and the fitter The practice of scraping surfaces true, applied to surface plates, machine slides and similar objects, was due to Sir Joseph Whitworth. It superseded the older and less accurate practice of grinding to a mutual fit. Now, with machines of precision, the practice of grinding has to a large extent displaced the more costly scraping

Files are classed with scrapes, for, although the points are keen, there is never any front rake. Collectively there is a shearing action because the rows of teeth are cut diagonally. The sectional forms (fig 22) and the longitudinal forms (fig 23) of the files are numerous, to adapt them to all classes of work In addition, the method of cutting, and the degrees of coarseness of the teeth, vary, being single, or float cut, or double cut (fig 24) The rasps are another group. Degrees of coarseness are designated as rough, middle cut, bastard cut, second cut, smooth, double dead smooth, the first named is the coarsest, the last the finest. The terms are relative, since the larger a file is the coarser are its teeth, though of the same name as the teeth in a shorter file, which are finer.

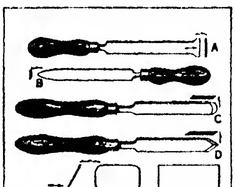

FIG. 21 —SCRAPES (A, B) METAL-WORKER'S SCRAPE; (C, D) ROUND NOSED AND DIAMOND POINT FOR WOOD-TURNING; (E, F) CABINET-MAKERS' SCRAPES

Shears and Punches.—These may be of cutting or non-cutting types. Shears (fig 25) have no front rake, but only a slight clearance. They generally give a slight shearing cut, because the blades do not lie parallel, but the cutting begins at one end and continues in detail to the other. But strictly the shears, like the punches, act by a severe detrusive effort; for the punch, with its bolster (fig. 26), forms a pair of cylindrical shears. The effect of shearing is practically identical with that of punching, and likewise planing and annealing shorn edges has substantially the same influence as reamering punched holes. *See* also SCREW.

HAMMERS AND MOULDING TOOLS

Hammers.—These form an immense group, termed percussive, from the manner of their use (fig. 27) Every trade has its own peculiar shapes, the total of which number many scores, each with its own appropriate name, and ranging in size from the minute forms of the jeweler to the sledges of the smith and boiler maker and the planishing hammers of the coppersmith Wooden hammers are termed mallets, their purpose being to avoid bruising tools or the surfaces of work Most trades use mallets of some form or another Hammer handles are rigid in all cases except certain percussive tools of the smithy, which are handled with withy rods, or iron rods flexibly attached to the tools, so that when struck by the sledge they shall not jar the hands The fullering tools, and flatters, and setts, though not hammers strictly, are actuated by percussion The dies of the die forgers are actuated percussively, being closed by powerful hammers The action of caulking tools is percussive, and so is that of moulders' rammers

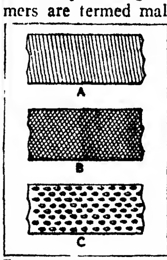

FIG 24 —FILE TEETH. (A) FLOAT CUT: (B) DOUBLE CUT: (C) RASP CUT

Moulding Tools.—This is a group of tools which, actuated either by simple pressure or percussively, mould, shape and model forms in the sand of the moulder, in the metal of the smith, and in press work. All the tools of the moulder (fig 28) with the exception of the rammers and vent wires act by moulding the sand into shapes by pressure. They are made in iron and brass. The fullers, swages and flatters of the smith, and the dies used with hammer and presses, all mould by percussion or by pressure, the

work taking the counterpart of the dies, or of some portion of them. The practice of die forging consists of moulding processes

For a discussion of Tool Steels see the article under that heading.

MEASUREMENT

An advance of the greatest importance made in mechanical engineering is that of measurement Since the beginning of the 19th century steady movement has been going on in this direction Methods of measurement adopted in woodworking have but little application in high-class engineers' work They are adopted, however, to a considerable extent in the metal trades which are allied to engineering, as sheet metal working, girder work, etc. When a carpenter or joiner sets about constructing a door, window sash, roof or box he takes a two-foot rule, a marker and possibly compasses Whether the tool used be saw, chisel, gouge or plane, the woodworker estimates by sight alone whether or not the lines marked are worked by.

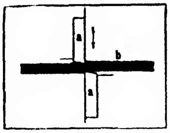

Fig 25.—Shear Blades (a, a) Blades. (b) Plates being sheared

The broad difference between his method and that of the engineer's machinist lies in this, that while the first tests his work by the eye, the second judges of its accuracy or otherwise by the sense of touch. It may seem that there cannot be very much difference in these two methods, but there is To the first, the sixty-fourth part of an inch is a fine dimension, to the second one-thousandth of an inch is rather coarse. In what are called "limit gauges" the plugs and rings are made of slightly different dimensions If a plug is made a thousandth of an inch less than its ring, it will slip through it easily with very perceptible slop The common rule is therefore scarcely seen in modern machine shops, while the common calipers fill but a secondary place, their function having been invaded by the gauges. A minute dimension cannot be tested by lines of division on a rule, neither can a dimension which should be fixed be tested with high precision with a movable caliper of ordinary type Yet it must not be supposed that the adoption of the system of gauging instead of the older methods of rule measurement relieves men of responsibility The instruments of precision require delicate handling. Rough forcing of gauges will not yield correct results. Without correctness of measurement mechanical constructions would be impossible, and the older device of mutual fitting of parts is of lessening value in face of the growth of the interchangeable system, of international standards, and of automatic machine tools.

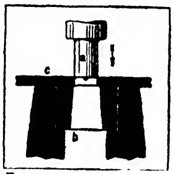

Fig 26.—Punching (a) Punch. (b) Bolster (c) Plate being punched

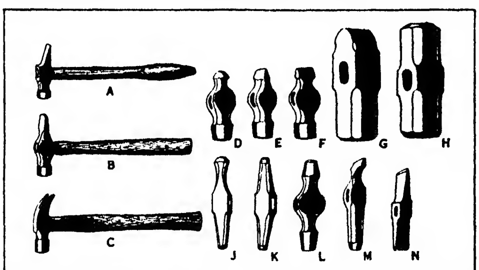

Fig 27—Hammers (A) Exeter. (B) Joiner's. (C) Canterbury Claw. (D, E, F) Engineer's (Ball, Cross and Straight Pane [Peen]). (G, H) Sledge Hammer, Straight Pane (Peen) and Double Faced. (J, K, L, M) Boiler Makers'. (N) Sealing

The two broad divisions of measurement by sight and by contact are represented in a vast number of instruments. To the first named belong the numerous rules in wood and metal and with English and metric divisions, and the scales which are used for setting out dimensions on drawings smaller than those of the real objects, but strictly proportional thereto. The second include all the gauges These are either fixed or movable, an important subdivision. The first embrace two groups—one for daily workshop service, the other for testing and correcting the wear of these, hence termed "reference gauges" They are either made to exact standard sizes, or they embody "limits of tolerance," *i.e*, allowances for certain classes of fits, and for the minute degrees of inaccuracy which are permissible in an interchangeable system of manufacture The movable group includes a movable portion, either corresponding with one leg of a caliper or having an adjustable rod, with provision for precise measurement in the form of a vernier or of a screw thread divided micrometrically These may be of general character for testing internal or external diameters, or for special functions as screw threads. Subtitles indicate some particular aspect or design of the gauges, as "plug and ring," "caliper," "horseshoe," "depth," "rod," "end measure," etc. So severe are the requirements demanded of instruments of measurement that the manufacture of the finer kinds remains a speciality in the hands of a very few firms The cost and experience necessary are so great that prices rule high

Rules and Scales.—The rules are used for marking off distances and dimensions in conjunction with other instruments, as scribers, compasses, dividers, squares, and for testing and checking dimensions when marked, and work in course of reduction or erection, directly or from calipers. They are made in boxwood and in steel, the latter being either rigid or flexible, as when required to go round curves Rules are fitted in combination with other instruments, as sliding calipers, squares, depth gauges, etc The scales are of boxwood, or ivory, the value of which is discounted by its shrinkage, and of paper They are fully divided, or open divided; in the first case each division is alike subdivided, in the second only the end ones are thus treated.

The Gauges. *Fixed Gauges*—These now embrace several kinds, the typical forms being represented by the cylindrical or plug and ring gauges and by the caliper form or snap gauges. The principle in each is that a definite dimension being embodied in the gauge, the workman has not to refer to the rule, either directly or through the medium of a caliper. This distinction, though slight, is of immense importance in modern manufacturing. Broadly it corresponds with the difference between the older heterogeneous and the present interchangeable systems.

Plug and Ring Gauges.—The principal ones and the originals

of all the rest, termed Whitworth gauges after the inventor, are the plug and ring gauges (fig. 29, *A* and *B*). The principle on which they depend is that if the two gauges are made to fit with perfect accuracy, without tightness on the one hand or slop on the other, then any work which is measured or turned and bored or ground by them will also fit with equal accuracy Bored holes are tested by the plug gauge, and spindles are tested by the ring gauge, and such spindles and holes make a close fit if the work is done carefully Of course, in practice, there is very much variation in the character of the work done, and the finest gauges are too fine for a large proportion of engineers' work. It is possible to make these gauges within $\frac{1}{50\,000}$ of an inch But they are seldom required so fine as that for shop use, $\frac{1}{6,000}$ is generally fine enough For general shop work the gauges are made to within about $\frac{1}{1,000}$ of an inch Standard gauges in which the plug and ring are of the same diameter will only fit by the application of a thin film of oil and by keeping the plug in slight movement within the ring Without these precautions the two would "seize" so hard that they could not safely be separated

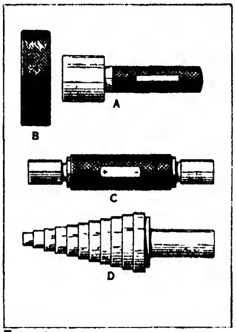

FIG 29 —GAUGES (A, B) PLUG AND RING, (C) DIFFERENCE, (D) STEPPED REFERENCE

Plug and Ring v. *Horseshoe Gauges*—The horseshoe, snap or caliper gauges (fig 30) are often used in preference to the plug and ring types

Limit Gauges—Some fits have to be what is termed in the shops "driving fits," that is, so tight that they have to be effected by driving with a hammer or a press, while others have to be "working fits," suitable, say, for the revolution of a loose pulley on its shaft or of an axle in its bearings The "limit" or "difference gauges" (figs 29 and 30) are designed for producing these working fits; that is, the plug and ring gauges differ in dimensions so that the work bored will drive tightly, or slide freely over the work turned These are variously sub-classified The system

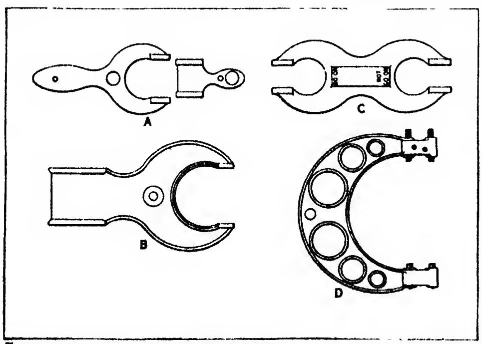

FIG 30 —GAUGES (A) SEPARATE CALIPER, (B) COMBINED INTERNAL AND EXTERNAL, (C) DIFFERENCE, (D) NEWALL ADJUSTABLE LIMIT GAUGE

which is generally accepted embraces *force fits*, which require the application of a screw or hydraulic press; *driving fits*, that require less power, as that of a hammer; *push fits*, in which a spindle can be thrust into its hole by hand, and *running fits*, such as that of shafts in bearings Fixed gauges are made for each of these, but as this involves a heavy outlay there are also adjustable limit gauges (fig. 30, *D*) for external dimensions, the standard plug being used for holes. The setting is done by screwed plugs or anvils adjusted by reference bars. In all these gauges the "go on" and "not go on" ends respectively are stamped on the gauge.

Reference Discs and End Measuring Rods—Shop working gauges become in time so damaged by service that they fail to measure so accurately as when new. To correct these errors

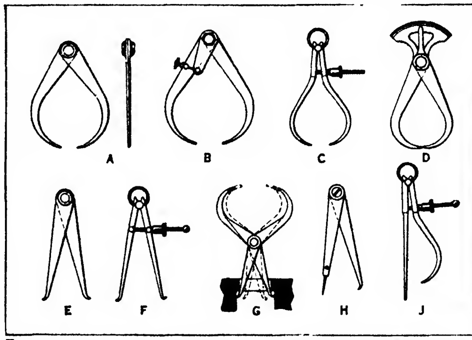

FIG 31 —CALIPERS (A) EXTERNAL, (B) TYPE ADJUSTED BY SCREW IN AUXILIARY LEG, (C) SCREW, (D) SELF-REGISTERING, (E) COMMON INTERNAL, (F) SCREW TYPE WITH SPRING, (G) COMBINED INTERNAL AND EXTERNAL (H) COMPASS, (J) KEYHOLE

reference gauges are provided These are never used in the shops for actual measurement of work, but are only kept for checking the truth of the working gauges They include disc,

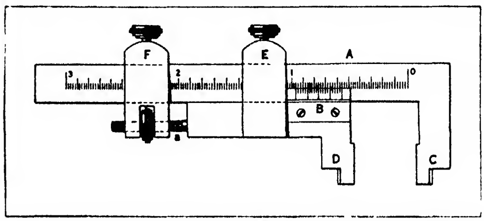

FIG. 32 —VERNIER CALIPER (A) BEAM, (B) VERNIER, (C) FIXED JAW, (D) MOVABLE JAW, (E) CLAMPING HEAD, (F) ABUTMENT HEAD WITH ADJUSTING SCREW, a, FOR ADJUSTMENT OF D

stepped and end measurement gauges The disc and the stepped are used for testing the ring gauges, the stepped kind comprising essentially a collection of discs in one piece (fig 29 *D*) The end

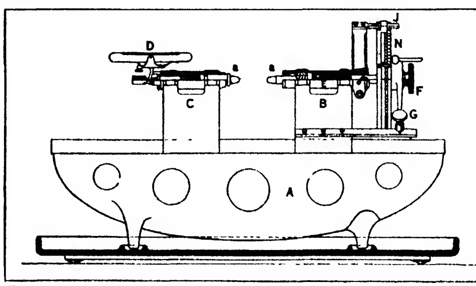

FIG 33 —MEASURING MACHINE (A) HOLLOW BASE, (B) MEASURING HEADSTOCK, (C) MOVABLE HEAD, (D) SPIRIT-LEVEL, (E) MEASURING SCREW, (F) NUT FOR ADJUSTMENT OF E, (G) KNOB FOR SLOW MOVEMENT OF E, (J) VERNIER a, a. POINTS BETWEEN WHICH CONTACT IS MADE

measure pieces test the external gauges. Some end measure standard lengths are so accurate that any sizes taken at random in any numbers from ¼ in to 4 in, varying by sixteenths of an inch, will, when placed end to end, make up an exact length.

Movable Gauges.—This extensive group may be regarded as compounded of the common caliper and the Whitworth measuring machine. They are required when precise dimensions have

to be ascertained in whole numbers and minute fractional parts. They combine the sense of touch by contact, as in the calipers, with the exact dimensions obtained by inspection of graduated scales, either the vernier or the micrometer screw. If gauges must not vary by more than $\frac{1}{10,000}$ of an inch, which is the limit

FIG 34.—MICROMETER CALIPERS (A) FRAMES. (B) ANVIL; (C) HUB. (D) SPINDLE WITH MICROMETER SCREW. (E) THIMBLE. a, ADJUSTING NUTS. b, CLAMPING NUT. c, RATCHET STOP

imposed by modern shop ideals, then instruments must be capable of measuring to finer dimensions than this. Hence, while the coarser classes of micrometers read directly to $\frac{1}{1000}$ part of an inch, the finest measure up to $\frac{1}{100,000}$ of an inch, about 200 times as fine as the diameter of a human hair.

Calipers.—Common calipers (fig. 31) are adjusted over or within work, and the dimensions are taken therefrom by a rule or a gauge

Vernier Calipers.—The vernier fitting, so named after its inventor, Pierre Vernier, in 1631, is fitted to numerous calipers and caliper rules. It is applied to calipers for engineers' use to read to $\frac{1}{1,000}$ of an inch without requiring a magnifier The beam of the caliper is divided into inches and tenths of the inch, and each tenth into fourths and the vernier into twenty-five parts, or the beam is divided into fiftieths of an inch (fig. 32) and the vernier has 20 divisions to 19 on the rule.

Micrometer Calipers are the direct offspring of the Whitworth measuring machine In the original form of this machine a screw of 20 threads to the inch, turned by a worm-wheel of 200 teeth and single-threaded worm, had a wheel on the axis of the worm with 250 divisions on its circumference, so that an adjustment of $\frac{1}{1,000,000}$ of an inch was possible. The costly measuring machines made to-day have a dividing wheel on the screw, but they combine modifications to ensure freedom from error, the fruits of prolonged experience. Such machines (fig. 33) are used for testing purposes, but there are immense numbers of small instruments, the micrometer calipers (fig 34), made for general shop use, measuring directly to $\frac{1}{1,000}$ of an inch, and in the hands of careful men easily to half and quarter thousandths. In these the subdivision of the turns of the screw is effected by circular graduations. Usually the screw pitch is 40 to the inch, and the circular divisions number 25, so that a movement of one division indicates that the screw has been advanced $\frac{1}{25}$ of $\frac{1}{40}$ or $\frac{1}{1,000}$ of an inch. Provision for correcting or taking up the effects of wear is included in these designs (*e.g.*, at *a* in fig. 34), and varies with different manufacturers. A vernier is sometimes fitted in addition, in very high class instruments, to the circular divisions, so that readings of ten thousandths of an inch can be taken. Beam micrometer calipers (fig. 35) take several inches in length, the micrometer being reserved for fractional parts of the inch only.

Depth and Rod Gauges.—It is often necessary to measure the depth of one portion of a piece of work below another part, or the height of one portion relatively to a lower one. To hold a rule perpendicularly and take a sight is not an accurate method, because the same objections apply to this as to rule measurement

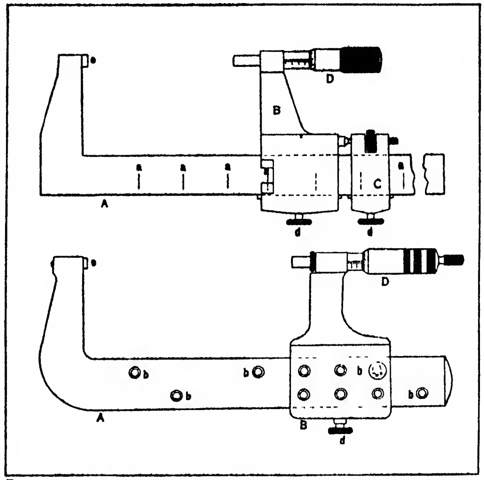

FIG. 35.—BEAM MICROMETER CALIPERS. (A) BEAM; (B) HEAD, ADJUSTABLE BY EQUAL INCH DIVISIONS, BY LINES a, a, OR HOLES b, b, AND PLUG b' HOLES. (C) ABUTMENT BLOCK WITH SCREW c FOR FINE ADJUSTMENT. d, CLAMPING SCREWS; (D) MICROMETER. e, ANVIL

in general There are many depth gauges made with rule divisions simply. These have the marked advantage of a shouldered face which rests upon the upper portion of the work, from which the rule measurement is taken (fig 36) These generally have

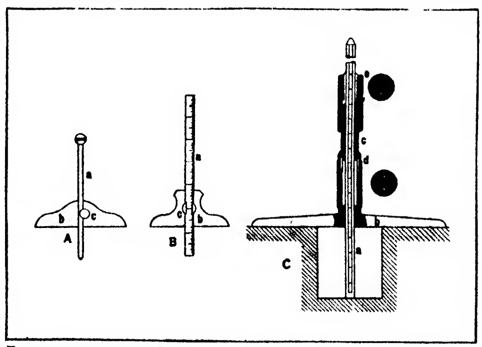

FIG 36.—DEPTH GAUGES: (A) PLAIN ROUND ROD a, SLIDING IN HEAD b, AND PINCHED WITH SCREW c; (B) GRADUATED RULE a, SLIDING ON HEAD b, IN GROOVED HEAD OF CLAMPING SCREW c; (C) SLOCOMB DEPTH GAUGE, FITTED WITH MICROMETER, a ROD, SLIDING IN HEAD, b, c HUB, d THIMBLE CORRESPONDING WITH SIMILAR DIVIDED PARTS IN MICROMETER CALIPERS, e CLAMPING SCREW

a clamping arrangement. For very accurate work either the vernier or the micrometer fitting is applied. For larger diameters are the rod gauges (fig. 37) to which the micrometer is fitted

Screw Thread Gauges.—The taking of linear dimensions, though provided for so admirably by the systems of gauging just discussed, does not cover the important section of screw measurement. This is a department of the highest importance. In most English shops the only test to-day of the size of a screw or nut

is the use of a standard screw or a standard nut. This method may suffice in many classes of work, but it is utterly unsuited to an interchangeable system; and when there is a fair amount of the latter firms sometimes make thread gauges of their own, in general form like the plug and ring gauges, using a hard quality of steel for small sizes or a tough quality of cast iron for the larger. These, though not hardened, will endure for a long time if treated carefully; but though very useful and far better than none at all they lack two essentials They are simply accommo-

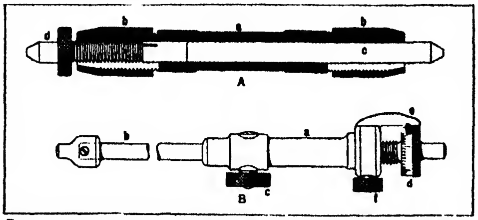

FIG 37.—ROD GAUGES. (A) PRATT & WHITNEY GAUGE, a. TUBE SPLIT AT ENDS, b, b. CHUCKS CLAMPING TUBE ON PLAIN ROD c, AND SCREWED END d, FINE ADJUSTMENT MADE BY SCREWED END d: (B) SAWYER GAUGE, a. dation gauges, made to an existing tap or die, and do not therefore embody any precise absolute measurement, nor do they include any means for measuring variations from standard, nor are they hardened The essence of a screw gauge is that it measures the sides of the threads without risk of a possible false reading due to contact on the bottom or top of the V This is fulfilled by flatting the top and making the bottom of the gauge keen Some gauges are made as a plug and ring (fig 38), the plug being solid and the ring capable of precise adjustment round it There is a plain round end, ground and lapped exactly to the standard size of the bottom of the thread, a dimension which is obliterated in the threaded end because of the bottoms of the angles being made keen for clearance There are three kinds of this class of gauge made; the first and most expensive is

BY COURTESY OF THE PRATT AND WHITNEY CO

FIG. 38—SCREW THREAD GAUGES. (A) PLUG GAUGE, (a) SIZE OF TAPPING HOLE, (b) THREAD; (B) RING GAUGE, (a) PINS TO PREVENT LATERAL MOVEMENT, (b) SCREW FOR OPENING GAUGE, (c) SCREW FOR CLOSING GAUGE

hardened and ground in the angle, while the second is hardened but not ground. The first is intended for use when a very perfect gauge is required, the second for ordinary shop usage. The third is made unhardened for purposes of reference simply, and it is not brought into contact with the work to be tested at all, but measurements are taken by calipers; in every detail it represents the standard threads. An appliance of quite a different character is a micrometer caliper having a fixed V and a movable point between which the screw to be measured is embraced.

Indicators are a small group of measuring instruments of a rather peculiar character. They magnify the most minute error by adaptations of long and short lever arms Some simply magnify inaccuracy, but in one type an index reads to thousandths of an inch (fig. 39). They are used in some lathe chuck work, but their principal value is in fitting and erecting the finer mechanisms

Surface Plates and Cognate Forms.—Allied to the gauges are the instruments for testing the truth of plane surfaces. the sur-

face plates, straight-edges and winding strips The origination of plane surfaces by scraping, until the mutual coincidence of three plates is secured, was due to Whitworth These surface plates (fig 40, *A*) fill an important place in workshop practice, since in the best work plane surfaces are tested on them and corrected by scraping To a large extent the precision grinding

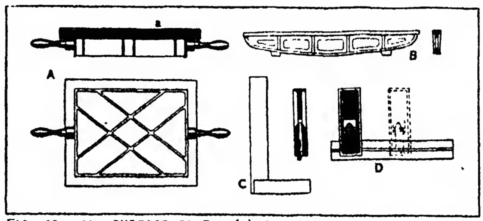

FIG 40—(A) SURFACE PLATE, (a) PROTECTING COVER FOR PLATE WHEN NOT IN USE, (B) LARGE RIBBED STRAIGHT-EDGE, (C) SQUARE; (D) SQUARE WITH ADJUSTABLE BLADE

machines have lessened the value of scraping, but it is still retained for machine slides and other work of a similar class In the shops there are two classes of surface plates those employed daily about the shops, the accuracy of which becomes impaired in time, and the standard plate or plates employed for test and correction Straight-edges are derived from the surface plates, or may be originated like them The largest are made of cast iron, ribbed and curved on one edge, to prevent flexure, and provided with feet (fig 40, *B*) The smaller straight-edges are generally parallel, and a similar pair constitutes "winding strips," by which any twist or departure from a plane surface is detected Squares, of which there are numerous designs (fig 40, *C* and *D*), are straight-edges set at right angles. Bevels or bevel-squares (fig. 41), are straight-edges comprising a stock and a blade, which are adjustable for angle in relation to each other. Shop protractors often include a blade adjustable for angle, forming a bevel with graduations Spirit-levels test the horizontal truth of surfaces. Many levels have two bubble tubes at right angles with each other, one of which tests the truth of vertical faces. Generally levels have flat

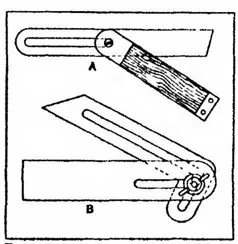

FIG 41—BEVELS (A) COMMON, (B) UNIVERSAL

feet, but some are made of V-section to fit over shafting. The common plumb-bob is in frequent use for locating the vertical position of centres not in the same horizontal plane When a plumb-bob is combined with a parallel straight-edge the term plumb-rule is applied It tests the truth of vertical surface more accurately than a spirit-level (J. G. Ho.)

TOOLE, JOHN LAWRENCE (1832–1906), English actor, was born in London on March 12, 1832 He was educated at the City of London School He definitely took to the stage in 1852, appearing in Dublin as Simmons in *The Spitalfields Weaver* In 1854 he made his first professional appearance in London at the St. James's theatre, acting Samuel Pepys in *The King's Rival* and Weazel in *My Friend the Major*. In 1857, he met Henry Irving in Edinburgh, and recommended him to go to London; and their friendship remained thenceforth of the closest kind In 1858 Toole joined Webster at the Adelphi, and established his popularity as a comedian In 1868 he was engaged at the Gaiety, appearing among other pieces in *Thespis*, the first Gilbert and Sullivan collaboration. In 1879 he took the "Folly" theatre in London, which he renamed "Toole's" in 1882. He died at Brighton on July 30, 1906. Toole excelled in what may be called Dickens parts—combining humour and pathos.

TOOL STEEL. This term includes steels used for machine tools, hand tools and cutlery. Prior to 1870 these were exclusively high carbon steels made by crucible or cementation process; since then alloy steels have been introduced for cutting metals Plain carbon steels of high quality are still pre-eminent for wood working, stone cutting and cutlery The amount of carbon ranges from 0.60 to 1 30% the lower carbon content giving a moderate hardness but great toughness Sledges, chisels, picks, rock drills, axes, woodworking tools, files, cutlery and razors, each item needs greater and greater hardness and more ability to maintain a cutting edge, with toughness progressively less important as the carbon content increases.

With carbon steels, if worked at high rates of speed, the friction between chip and tool-nose generates enough heat to "draw the temper" of the tool, that is, to soften it to a lesser hardness than the material being cut This is avoided by using special alloys that temper very slowly, retain their hardness at high heats, or are intrinsically hard and require no heat treatment. Mushet steel (*q v*) is of the first category, and was introduced about 1870 High speed steel (*q v*), which has the property of hardness at a red heat, is now widely used in machine shops for mass production of iron and steel parts Stellite (although really not a steel) is an example of the third class of hard tool material Another material of the greatest hardness, introduced in 1928, is an alloy of tungsten carbide with up to 12% cobalt, that has already proven very useful for tough or abrasive substances like aluminium bronze, Hadfield's manganese steel and non-metallic electrical insulation.

As explained in the last paragraphs of the article on "Iron and Steel," carbon steels owe their hardness after quenching to submicroscopic particles of hard iron carbide cemented together with the softer ferrite (pure iron). Mushet found that the metals tungsten and chromium combined with high-carbon steel slowed down the softening reactions, so that a drastic quenching from a high heat was unnecessary. In 1900, Taylor and White disclosed the fact that, if Mushet's air-hardening tungsten-chromium steels were cooled from a sweating temperature and then tempered at a high heat, they would retain their hardness at a red heat. Progress since then has come in working out the optimum composition in tungsten, chromium, carbon and vanadium The revolution in machine shop practice was primarily due to the hardening and stabilizing effect of tungsten, chromium and iron carbides in tool steel. More recently the addition of the metal cobalt in amounts up to 15% has been found to give a more durable cutting edge at a red heat. Meanwhile Elwood Haynes had discovered stellite, a family of alloys essentially of tungsten, chromium and cobalt This alloy soon established itself for machining hard cast iron ("semi-steel") and for rough turning medium steels Variants of the composition have been used for wire-drawing dies. But this swing to hard *metals* seems to be a passing phase The newest tool material is a hard carbide of tungsten with a softer cobalt metal as a binder

Chemical composition of the commonly used tool steels are as shown in table at bottom of this page Sulphur and phosphorus are held to the lowest possible content

See Iron and Steel (E E T)

TOOMBS, ROBERT (1810–1885). American political leader, was born near Washington, Wilkes county, Ga, on July 2, 1810 He was educated at Franklin college (University of Georgia), at Union college, Schenectady (N Y), from which he graduated in 1828, and at the law school of the University of Virginia He was admitted to the bar in 1830, served in the Georgia House of Representatives (1838, 1840–41 and 1843–44), in the U S House of Representatives (1845–53), and in the United States Senate (1853–61). He opposed the annexation of Texas, the Mexican War, President Polk's Oregon policy, and the Walker Tariff of 1846 He supported the Compromise Measures of 1850, denounced the Nashville Convention, opposed the secessionists in Georgia, and helped frame the Georgia platform (1850) He and the Southern Unionists thought secession not wrong but inexpedient When the Whig party dissolved, Toombs went over to the Democrats. He favoured the Kansas-Nebraska Bill, the admission of Kansas under the Lecompton Constitution, the English Bill (1858), and June 24, 1856, introduced in the Senate the Toombs Bill, which proposed a constitutional convention in Kansas under conditions, acknowledged by anti-slavery leaders as fair and marking the greatest concessions by the pro-slavery senators during the Kansas struggle. The failure of the bill to provide for the submission of the constitution to popular vote was the crux of the Lecompton struggle (*see* Kansas) On December 22nd after the election of Lincoln, he sent a telegram to Georgia which asserted that "secession by the 4th of March next should be thundered forth from the ballot-box by the united voice of Georgia"

With Governor Joseph E Brown he led the fight for secession against Stephens and Herschel V. Johnson (1812–80). His influence induced the "old-line Whigs" to support immediate seces-

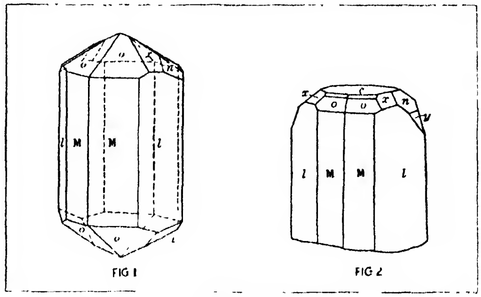
TOOTHWORT, the popular name for a small British plant of curious form and growth, known botanically as *Lathraea squamaria* (family Orobanchaceae). It grows parasitically on roots, chiefly of hazel, in shady places such as hedge sides It consists of a branched whitish underground stem closely covered with thick fleshy colourless leaves, which are bent over so as to hide the under surface; irregular cavities communicating with the exterior are formed in the thickness of the leaf On the inner wall of these chambers are stalked hairs. The only portions that appear above ground are the short flower-bearing shoots, which bear a spike of two-lipped dull purple flowers The scales which represent the leaves secrete water *Lathraea* is closely allied to broomrapes (*Orobanche*), of which seven species occur in Great Britain, they also are parasitic In the United States various species of *Dentaria*, family Cruciferae, are called toothwort

TOOWOOMBA, a city in the south-east of Queensland, Australia, situated at an altitude of nearly 2,000 ft on the Darling Downs, 101 m by rail west of Brisbane Toowoomba is an industrial centre, it is also a well-known summer resort ("The Garden City of Queensland"), is situated upon the Main Southern and Western Railway lines which connect it with Brisbane and Sydney, and it is also a centre of radiating lines which concentrate upon it much of the agricultural and pastoral produce of the Darling Downs, besides timber, and the wheat, fruit, and pastoral products of the farther West, Roma (*q v*) and Charleville areas

TOP (*cf* Dan *top*, Ger *Topf*, also meaning pot), a toy consisting of a body of conical, circular or oval shape with a point or peg on which it turns or is made to whirl Greek terms for the toy are *βέμβιξ*, which was evidently the whipping or peg-top (Arist. *Birds*, 1461), and *στρόβιλος*, a humming top, spun by a string (Plato, *Rep.* iv 436 E) In Homer (*Il.* xiv 413) the word *στρόμβος* seems to point to the humming top The Latin name for the top was *turbo* This word and the Greek *ῥόμβος* are sometimes translated by "top" when they refer to the instrument used in the Dionysiac mysteries, which, when whirled in the air by a string, produced a booming noise This was no doubt the equivalent of the "bull roarer" (*q v*) Strutt (*Games and Pastimes*, 491) says that the top was known in England as early as the 14th century For the scientific properties of the top *see* GYROSCOPE

TOPAZ, a mineral of some importance as a gemstone, but apparently having no practical application. It usually occurs in association with cassiterite in connection with granitic rocks, and it is thus often a valuable indicator of the presence of tin-ore. It is usually found as bright, well-developed crystals, or as clear water-worn pebbles, though granular masses of topaz-rock are also known The crystals belong to the orthorhombic system and are usually prismatic in habit, with several dome and pyramid faces (figs. 1 and 2). The prism faces (*M* and *l*) are striated vertically, in contradistinction to quartz in which the prism faces are striated horizontally Doubly terminated crystals (fig. 1) are extremely rare; usually the crystals are attached at one end in the rock cavities in which they grew, and when detached from the matrix they often break along a flat surface parallel to the basal plane (*c* in fig 2) This perfect cleavage is a very important character, and enables topaz to be distinguished at sight from other minerals of similar appearance. The cleavage flakes when examined in convergent polarized light show a good biaxial interference-figure. Chemically, topaz is a fluo-silicate of aluminium $(AlF)_2SiO_4$, in which the fluorine is in part replaced isomorphously by hydroxyl, the formula then being $(Al[F,OH])_2SiO_4$. With this range in chemical composition there is a slight variation in the specific gravity (3 574 to 3 523) and in the optical constants



FIGS 1 AND 2

(refractive indices and optic axial angle), but the difference is of little practical importance

The crystals are often perfectly colourless and water-clear, but owing to the presence of traces of various colouring matters they may show a wide range of colours—red, yellow, brown, green, blue Further, it is an interesting fact that some of these colours are by no means stable The fine brown crystals from pegmatite veins in Transbaikalia, Siberia, and the smaller wine-yellow crystals occurring in rhyolite in Colorado and Utah, fade on exposure to light, and the sherry-yellow crystals from Brazil assume a fine pink colour when they are heated The deceptive trade-names—"Scotch topaz," "Spanish topaz," or "occidental topaz" for yellow quartz (citrine), and "oriental topaz" for yellow corundum ("yellow sapphire") represent three distinct minerals whose characters and differences are set out in the following table

	Topaz	Quartz	Corundum
Chem. comp	$(AlF)_2SiO_4$	SiO_2	Al_2O_3
Cryst system	Orthorhombic	Rhombohedral	Rhombohedral
Specific gravity	3·55	2·65	4 0
Hardness	8	7	9
Optical character	Biaxial positive	Uniaxial positive	Uniaxial negative
Refractive indices	1 61–1·63	1 54 1·55	1·76–1·77

The sherry-yellow crystals of topaz, which in the past have been cut and extensively used in jewellery, are all from the neighbourhood of Ouro Preto, in Brazil, and it is this material that has supplied the pink ("burnt") topaz Brazil also supplies colourless and pale-blue topaz Good crystals of pale blue and green colours have come from the Ural Mountains and from Nerchinsk in Siberia. Colourless water-worn crystals and clear pebbles resembling rock-crystal are abundant in the alluvial deposits of tin-ore in Northern Nigeria, and small colourless crystals are well known from the Cornish tin mines A large rough crystal weighing 137 lb of opaque topaz, from a felspar quarry in Norway, is shown in the mineral collection of the British Museum (Natural History), with many other interesting crystals from various localities (L J. S)

TOPE, name given to various tumulus-like structures in India almost always connected with Buddhist shrines or sites and forming, undoubtedly, the most primitive type of Buddhist temple They are usually built over, enclose one or more relics of Buddha, and consist of a low, vertical, cylindrical wall or drum surmounted by a solid conical mass of carefully built masonry The most famous of the Indian topes is the largest of a group at Sanchi, which is generally attributed to the time of Asoka (3rd century B C) In this the tope proper is surrounded by a circular walk around which is a richly decorated stone fence, pierced by four lavishly sculptured gateways, the whole designed in forms mani-

festly reminiscent of wooden construction. (*See* INDIAN ARCHITECTURE.) The Sanskrit word for a tope, *stupa*, is used generally of various types of sacred Buddhist structures in China, Japan, Java, etc., which all have the common characteristic of being high circular masses of solid masonry. Those of Tibet and China are often remarkable for their fantastic profiles

TOPEKA, the capital city of Kansas, U.S A., and the county seat of Shawnee county; on the Kansas (Kaw) river, in the eastern part of the State, 70 m. W. of Kansas City. It is on Federal highways 40 and 75; has a municipal airport; and is served by the Missouri Pacific, the Rock Island, the Santa Fe and the Union Pacific railway systems. Pop (1920) 50,022 (83·4% native white, 8·0% foreign-born white and 8·5% Negro); estimated locally in 1928 at 62,000 (within the city limits) and 72,500 including adjacent suburbs. The city lies on both sides of the river, at an elevation from 880 to 1,000 ft. above sea-level. It is laid out on the rectangular plan, with broad, well-paved, beautifully shaded streets, substantial business blocks, many playgrounds for children, and 300 ac of public parks. The State Fair grounds, on the edge of the city, cover 78 ac. and include a fine half-mile race-track and numerous permanent exhibition buildings The State capitol (built 1866–1903, at a cost of $3,200,589) stands in the center of parked grounds covering four squares. Topeka is the seat of a Protestant Episcopal cathedral, a State hospital for the insane, a State reform school, the collections of the State historical society, several hospitals (including one for employees of the Santa Fe lines) and private schools, the Kansas Vocational school for negroes (1895), and Washburn college (established in 1865 as Lincoln college, and renamed in 1865 in recognition of a gift of $25,000) which has an enrolment of over 1,200. The city is an important manufacturing center, with an output in 1926 valued at $37,457,732 The Santa Fe has its principal construction shops here, employing 3,500 men, and its offices have a staff of 1,500 officials and clerks The flour-mills make 1,500,000 bbl of flour and 400,000 bbl. of corn-meal annually. Printing and publishing (20 houses) is one of the leading industries. The assessed valuation of property for 1928 was $93,683,060.

Topeka is an Omaha Indian word signifying the so-called Indian potato The first white settler came in 1852, and in 1854 the site was chosen by a group of anti-slavery colonists from Lawrence. It was the scene of many riots during the conflict between the abolitionists and the advocates of slavery in the Territory (*see* KANSAS). The "Topeka Constitution" was framed by a convention here in 1855. In 1856 the Free Soil legislature, meeting here, was dispersed by U S. troops under orders from President Pierce. Under the Wyandotte Constitution (1859) Topeka was made the temporary seat of government, and in 1861 (when Kansas was admitted to the Union) it became the permanent State capital. The city was chartered by the pro-slavery Territorial legislature in 1857. It became a city of the first class in 1881. It was from Topeka that the Santa Fe company began building a railway westward in 1869, and the establishment here in 1878 of its locomotive and car construction shops was an important factor in the city's development. The population increased rapidly from 759 in 1860 to 5,790 in 1870, 15,452 in 1880 and 31,007 in 1890. In 1880, just after the great negro migration to Kansas, 31% of the total population of the city was coloured, but in 1928 the proportion was not more than 7%.

TOPETE, JUAN BAUTISTA (1821–1885), Spanish naval commander and politician, was born in Mexico on May 24, 1821. His father and grandfather were also Spanish admirals. He entered the navy at the age of 17, cut out a Carlist vessel in 1839, became a midshipman at 22, obtained the cross of naval merit for saving the life of a sailor in 1841 and became a lieutenant in 1845. He served on the West Indian station for three years, and was engaged in repressing the slave trade before he was promoted frigate captain in 1857. He was chief of staff to the fleet during the Morocco War, 1859, after which he got the crosses of San Fernando and San Hermenegildo. Having been appointed chief of the Carrara arsenal at Cádiz, he was elected deputy and joined the Union Liberal of O'Donnell and Serrano. He was sent out to the Pacific in command of the frigate "Blanca," and was present at the bombardment of Valparaiso and Callao, where he was badly wounded, and in other engagements of the war against Chile and Peru. On his return to Spain, Topete was made port captain at Cádiz, which enabled him to assume the leadership of the conspiracy in the fleet against the Bourbon monarchy. He sent the steamer "Buenaventura" to the Canary isle for Serrano and the other exiles; and when Prim and Sagasta arrived from Gibraltar, the whole fleet under the influence of Topete took such an attitude that the people, garrison and authorities of Cádiz followed suit. Topete took part in all the acts of the revolutionary government, accepted the post of marine minister, was elected a member of the *cortes* of 1869, supported the pretensions of Montpensier, opposed the election of Amadeus, sat in several cabinets of that king's reign, was prosecuted by the Federal republic of 1873 and again took charge of the marine under Serrano in 1874. After the Restoration Topete for some years held aloof, but finally accepted the presidency of a naval board in 1877, and sat in the Senate as a life peer until his death on Oct. 29, 1885 at Madrid.

TÖPFFER, RODOLPHE (1799–1846), Swiss writer and artist, son of the painter Adam Topffer, was born at Geneva on Jan. 31, 1799. Abandoning his art studies on account of weak eyesight, he became a teacher, eventually establishing a school of his own (1824), which attracted boys from England and America as well as from other European countries He was the first to introduce schoolboy tramps in the Alps, and he described these in his *Voyages en Zigzag*, illustrated by clever drawings by himself. From 1832 till his death, on June 8, 1846, he was professor of belles-lettres at the university of Geneva He wrote various novels and short stories, including the exquisite little masterpiece, *La Bibliothèque de mon Oncle* (1833). His tales were collected under the title *Nouvelles Génevoises* (1841), and several have been translated into English. His series of humorous drawings with explanatory text (*Doctor Festus, Monsieur Vieux-Bois*, etc.), collected under the title of *Histoires en Estampes* (1846–47), were very popular and earned the cordial approbation of Goethe.

See the lives by Relave (1886), A. Blondel (1887) and Glöckner (1891). Also E Rambert, *Écrivains nationaux* (1874), E Javelle, *Souvenirs d'un alpiniste* (1886, Engl. trans, 1899), and notices in Ste. Beuve's *Causeries du lundi* (1852–62), *Derniers portraits littéraires* (1852) and *Portraits contemporains* (1846).

TOPOLOGY: *see* ANALYSIS SITUS.

TORADJA, a group of tribes occupying central Celebes, in the Indonesian archipelago. They possess in common a phallic fertility cult and some of them practise terraced cultivation, erect menhirs and bury their dead in rock-cut tombs They possess, among others, a culture hero who is believed to have introduced the buffalo and to have ascended to heaven by a creeper; they believe in an underground home of the dead, and have a class of male priests who dress in women's clothes; the soul, which is also connected with the sky, takes the form of a manikin, insect, small animal, etc., located in the head, but is also confused with shadow and is in some sense a material substance coextensive with body and liable to impregnate objects (*see* METEMPSYCHOSIS).

See Kruijt, *Het Animisme in den Indischen Archipel.* (1906); Kruijt and Adriani—*De Bare'e—sprekende Toradj's* (1914).

TORBERNITE, (or cupro-uranite), a hydrous uranium and copper phosphate, $Cu(UO_2)_2(PO_4)_2+12H_2O$, one of the "uranium micas." Crystals are tetragonal and have the form of square plates, often very thin. There is a perfect micaceous cleavage parallel to the basal plane, and on this face the lustre is pearly. The bright grass-green colour is characteristic. The hardness is 2·5 and specific gravity 3 5. The radio-activity of the mineral is greater than that of some specimens of pitchblende. It was first observed in 1772 at Johanngeorgenstadt in Saxony, but the best examples are from Gunnislake near Calstock and Redruth in Cornwall. The name torbernite is after Torbern Bergman: *chalcolite* is a synonym. The crystals readily lose part of their water, passing over into "meta-torbernite" $Cu(UO_2)_2(PO_4)_2+8H_2O$, with changes in the optical characters. (L. J. S.)

TORCELLO, an island of Venetia, Italy, in the lagoons, 6 m. to the N.W. of Venice. It was a flourishing city in the early middle ages, but now has 171 inhabitants and two interesting churches.

PHOTOGRAPH, WIDE WORLD PHOTOS

VIEW OF AN APPROACHING TORNADO

Tornado approaching Vulcan, Alberta, Canada. The destructive power is not in the straight wind, but in the counter-clockwise rotating mass which always moves in an easterly, and generally in a north-easterly direction. Barometric pressure in the vicinity of a tornado falls very rapidly

TORNADO

TORNADO VIEWED AT AN ANGLE FROM ITS PATH

Side view of a funnel-shaped tornado cloud sweeping in a path 50 ft. wide across the country near Jasper, Minnesota. The violent local whirl characterized as a tornado is set up in the south-east quadrant of a slowly moving cyclone. The clouds and the earth, having opposite charges of electricity, are attracted. The tornado pictured here travelled only three miles

The former cathedral of S. Maria was founded in 641. The present building, a basilica with columns, dates from 864; the nave was restored in 1008, in which year the now ruined octagonal baptistery was built. It contains large mosaics of the 12th century, strongly under Byzantine influence; those on the west wall represent the Resurrection and Last Judgment. The seats for the priests are arranged round the semicircular apse, rising in steps with the bishop's throne in the centre—an arrangement unique in Italy. Close by is S. Fosca (*ca.* 1011), octagonal outside, with colonnades on five sides and a rectangular interior intended for a dome which was never executed, beyond which is a three-apsed choir.

See B. Schulz, *Kirchenbauten auf dem Insel Torcello* (Berlin and Leipzig, 1927)

TORDENSKJOLD, PEDER (1691–1720), Danish naval hero, son of Jan Wessel of Bergen, in Norway, was born at Trondhjem on Oct. 28, 1691. Wessel ran away from home as a stowaway in a ship bound for Copenhagen, made a voyage to the West Indies, and finally gained a cadetship. In 1712 he was promoted to a 20-gun frigate. Wessel was renowned for his audacity and his unique seamanship. The Great Northern War had now entered upon its later stage, when Sweden, beset on every side, employed her fleet principally to transport troops and stores to her distressed German provinces. The audacity of Wessel impeded her at every point He was continually snapping up transports, dashing into the fjords where her vessels lay concealed.

When in 1715 the return of Charles XII. from Turkey to Stralsund put a new life into the jaded Swedish forces, Wessel fought numerous engagements off the Pomeranian coast, and did the enemy infinite damage by cutting out their frigates and destroying their transports On returning to Denmark in the beginning of 1716 he was ennobled under the title of "Tordenskjold" (Thundershield). When Charles XII invaded Norway and besieged Fredrikshald (1716) Tordenskjold compelled him to raise the siege and retire to Sweden by pouncing upon the Swedish transport fleet laden with ammunition and other military stores which rode at anchor in the narrow and dangerous strait of Dynekil, utterly destroying the Swedish fleet with little damage to himself For this, his greatest exploit, he was promoted to the rank of commander

Tordenskjold's last feat of arms (he was now rear-admiral) was his capture of the Swedish fortress of Marstrand, when he partially destroyed and partially captured the Gothenburg squadron which had so long eluded him He was rewarded with the rank of vice-admiral Tordenskjold did not long survive the termination of the war. On Nov 20, 1720, we was killed in a duel with a Livonian colonel, Jakob Axel Stael von Holstein. Although, Dynekil excepted, Tordenskjold's victories were of far less importance than Sehested's at Stralsund and Gyldenlöve's at Rügen, he is certainly, after Charles XII, the most heroic figure of the Great Northern War

See Carstensen and Lütken, *Tordenskjold* (Copenhagen, 1887).
(R. N. B.; X.)

TORELL, OTTO MARTIN (1828–1900), Swedish geologist, born in Varberg on June 5, 1828, studied the glacial phenomena of Switzerland, Spitsbergen and Greenland, making two Arctic expeditions in company with A. E Nordenskiöld. In 1866 he became professor of zoology and geology in the University of Lund, and from 1871 to 1897 he was chief of the Swedish Geological Survey. His Arctic experiences enabled him to interpret the method of origin of the drift deposits in northern Europe, and to show that they were largely of glacial or fluvio-glacial origin. In the English drifts he recognized many boulders of Scandinavian origin. He died on Sept. 11, 1900.

TORENO, JOSÉ MARIA QUEIPO DE LLANO, COUNT OF (1786–1843), Spanish politician and historian, born at Oviedo, Nov. 25, 1786. He saw service in the Peninsular war, was leader of the party which compelled the regency to summon the *cortes*, and one of the well-meaning men who framed the Constitution of 1812, which was made as if it was meant for some imaginary republic and not for Catholic and monarchical Spain. On Ferdinand VII.'s return from prison in France in 1814, Toreno exiled himself until 1820; served in the restored *cortes* until 1823; and lost much of his radical ardour. From 1823 when the French intervened until the amnesty (Oct. 15, 1832), he had to go into exile; he returned home in July 1833, and as hereditary standard bearer of Asturias (Alferez mayor), it fell to him to proclaim the young queen Isabella II. Prime minister in 1834 from June 7–Sept. 14, when the regent's attempt to retain a despotic government under a constitutional veil broke down, he retired into voluntary exile and died in Paris, Sept. 16, 1843

TORGAU, a town in the Prussian province of Saxony, situated on the left bank of the Elbe, 30 m. E N.E of Leipzig and 26 m. S.E. of Wittenberg by rail. Pop (1925) 12,616. Torgau is said to have existed as the capital of a distinct principality in the time of the German king Henry I., but early in the 14th century it was in the possession of the margraves of Meissen and later of the electors of Saxony. In 1526 John, elector of Saxony, Philip, landgrave of Hesse, and other Protestant princes formed a league against the Roman Catholics, and the Torgau articles, drawn up here by Luther and his friends in 1530, were the basis of the confession of Augsburg. Torgau was formally ceded to Prussia in 1815. The Schloss Hartenfels, on an island in the Elbe, was built by John Frederick the Magnanimous, of Saxony.

Battle of Torgau, 1760.—This, the last great battle of Frederick the Great, and the last of his victories, was so truly Pyrrhic that it paralysed his offensive power and left him in a gravely weakened condition to meet his gathering foes The battle and the events which rescued him from his critical position are dealt with under SEVEN YEARS WAR

TORNADO, the name originally applied to the violent squall blowing outwards from the front of a thunderstorm on the Gold Coast of Africa; it is now used for small-diameter, but extremely violent, revolving storms which are specially frequent in the Mississippi basin, but are also experienced elsewhere, in Australia especially, Europe and many other places, but commonly in a less violent form They normally occur in the spring and early summer months in association with cyclones The most violent tornadoes are always accompanied by a tornado-cloud, a funnel-shaped mass depending from the storm-cloud above, and when fully developed tapering downward to the earth. A tornado has an advancing movement of from 20 to 50 m. an hour, and its narrow path is strewn with wreckage; the storm is of short duration; it passes in a minute or so and often runs its entire course in less than an hour.

See A. Wegner, *Wind und Wasserhosen in Europa* (Braunschweig, 1917); and for Mississippi tornadoes *see* R. de C. Ward, *Q.J.R. Met. Soc.* (1917); also *Monthly Weather Review*, v. 54, p. 501 (1926).

TORNADO AND WINDSTORM INSURANCE. Windstorm damage is one of the major sources of economic loss in many localities. In the United States windstorm insurance should be general and considered an essential form of contingency protection against unavoidable losses inherent to the climate. The policies cover tornado, cyclone and windstorm but do not provide for snow, blizzards, cold or hail even when driven by wind (*See* INSURANCE, MISCELLANEOUS: *Hail Insurance.*) Many forms are issued to cover a great variety of structures, such as "farm form," "builders risk form," "mercantile property form." Rates vary with the kind of property insured, the section of the country in which it is situated, co-insurance and special endorsements. The premiums in the United States with 50% co-insurance ranged, in 1925, from 6 cents to $3 per $100 insurance, depending on position and type of structure. The rates are computed on a basis of 50% co-insurance, and special provision is made for other percentages. By endorsement the policies may be made to cover use and occupancy.

TORO, a town of Spain, in the province of Zamora, on the right bank of the river Duero (Douro), and on the Zamora-Medina del Campo railway. Pop. (1920), 7,541. Toro is an ancient fortified town, with picturesque narrow streets. A fine bridge spans the river. The cathedral church is Romanesque; it dates from the 12th century but has been partially restored The palace of the marquesses of Santa Cruz was the meeting place of the Cortes of 1371, 1442 and 1505, which made Toro and its code of laws celebrated.

TORONTO, the capital of the province of Ontario, and the second largest city in the Dominion of Canada, situated on the northern shore of Lake Ontario, almost due north from the mouth of the Niagara river. It lies on a plateau gradually ascending from the lake shore to an altitude of 300 ft, and covers approximately forty square miles, including the bay and the island stretching along the south of the city. The river Don flows through the eastern part of the city, and the river Humber forms its western limit

Toronto, as the seat of government for the province of Ontario, contains the parliament buildings, the lieutenant-governor's residence, and the courts of law. In Queen's park (area 40 ac.) almost in the centre of the city, stand the parliament buildings, imposing structures of red sandstone; and immediately opposite there was opened in 1928 a large and beautiful addition in blue dolomite stone, called the "Whitney block"

The university, with a roll of 6,000 students in 1928, is federal in constitution, and is composed mainly of four colleges, though maintaining important university functions conjointly. It has made very important developments in the study of problems of health This has been made possible largely by gifts of $1,148,901 for the faculty of medicine from the Rockefeller Foundation, $650,000 from the International Health Board of the Rockefeller Foundation, and $400,000 from the E. C. Whitney Bequest A special building has been devoted, as a branch of the Connaught laboratories, to the study of insulin Recently a faculty of music, a school of engineering research and a department of social science and administration have been organized. There is a University press, and in Hart House and Queen's Park House respectively the men and women students have centres for social and athletic activities Affiliated with the university are denominational colleges near by, the agricultural college at Guelph, etc.

Toronto is rich in other institutions for higher education Upper Canada college, founded in 1829, in many respects resembles an English public school There are 9 collegiate institutes, 2 high schools of commerce, and 2 technical schools, having some 35,000 pupils (1927), about 150 public and separate schools, with an attendance of over 100,000 (1927), and several large private schools for girls Osgood hall houses the higher courts of law and appeal, and also a law school The city hall and courthouse contains civic offices, the board of education, police and county courts, etc There are in Toronto 72 hospitals, asylums and public homes, including ten public hospitals, the largest of which is the Toronto General Hospital in the centre of the city, which in 1927 accommodated approximately 15 000 patients

Toronto is essentially a residential and widespread city The houses of the better class stand separate, not in long rows, and have about them lawns and many trees There are over 90,000 homes, 65% owned by the occupiers An electric railway system and 9 motor bus routes, owned by the city, provide means of communication. There are no underground or overhead railways. Lighting is provided by the publicly owned Hydro-electric Power Commission. There are 69 parks with a total area of 2,065 acres. In Exhibition park (240 acres) there is held each year for a fortnight in the late summer a large annual exposition.

Government and Industries.—The government of the city is vested in a council consisting of the mayor and four controllers elected annually, and twenty-four aldermen, three from each of the eight wards into which the city is divided. The council as a whole is the legislative body, and the board of control is the executive body, and as such is responsible for the administration of the city, except the departments of education and of police Education is under the control of the board of education elected annually by the citizens, and the department of police is under the board of police commissioners, consisting of the mayor, the county judge, and the senior police magistrate.

Because of its geographical position, its cheap electric power, and its nearby sources of raw material, Toronto is one of the chief industrial and commercial centres of the dominion. It is also considered the publishing centre. It has eleven miles of water-front and the largest vessels of the lakes can use its harbour, which is under an extensive scheme of improvements, and will eventually be equipped to handle ocean shipping. In 1927 the magnificent new union station was opened, although the raising of the level of the tracks has not yet been completed.

Bank clearings for 1927 were $6,484,985,045, an increase over the previous year of $1,288,556,862 There are approximately 2,000 industries, in which capital to the amount of $448,839,685 is invested, and which employ 85,229 persons

The population in 1927 was 569,899, predominantly British; and it is estimated at 600,000 for 1928 More than 110,000 people reside in suburbs immediately adjacent to the city boundaries In 1885 the total assessment was $69,000,000; in 1906 it was $167,861,755; in 1926 it was $886,839,808; and in 1928 it was $926,027,622 The rate for 1928 was 31 80

History.—The name Toronto is of Indian origin, and means "a place of meeting," the site being an established rendezvous among the neighbouring Indian tribes long before the coming of the white man It first appears in history in 1749 as a centre of trade when the French built a small fort and established a trading post called Fort Rouillé Before long, however, British traders came up from the south and entered into rivalry with the French, and in 1793 the fort was burned by the latter to prevent its occupation by their foes A year later John Graves Simcoe, the governor of the new province of Upper Canada, transferred the seat of government from the town of Newark at the mouth of the Niagara river to Toronto, giving the new capital the name of York, in honour of the second son of George III. In 1812, the buildings which housed the legislature were burned and the town pillaged After the restoration of peace the work of creating a capital for the province of Upper Canada had to be begun anew In 1834 its population numbered about 10,000; and an act of the provincial legislature conferred on it a charter of incorporation, with a mayor, aldermen and councilmen Under this charter it was constituted a city with the name of Toronto

TORONTO, a village of Jefferson county, Ohio, U S A, on the Ohio river, 40 m W. of Pittsburgh; served by the Pennsylvania railroad, interurban trolley and motor-bus lines, and river steamboats Pop (1920) 4,684 (88% native white) It has a power plant and various manufacturing industries, including steel works, paper mills and factories making sewer pipe, etc.

TORPEDOES. In 1805 Robert Fulton, an American citizen, demonstrated a method of destroying ships by exploding a charge of gunpowder against the hull under water This charge was called a "torpedo" and the difficulty of getting it to a ship retarded for many years its progress as a practical weapon Attempts were first made to bring the torpedo into contact with the vessel by allowing it to drift down with the tide or current, or to fix it from some form of diving boat, but successive failures led to torpedoes being restricted to the form of submarine mines (*q v*) in which the charge is stationary and is fired when the ship strikes or passes over it. The inherent limitations of mines revived efforts to take the torpedo to the ship and the first practical weapon was the *spar, or outrigger, torpedo* This consisted of an explosive charge fixed to the end of a long pole carried in a boat, the pole being run out over the bow and the charge immersed on arriving near the ship Directly the charge came into contact with the hull it was exploded electrically. Frequent use of this weapon was made during the American Civil War On one occasion Lieutenant Cushing took a steam launch equipped with spar torpedo up the Roanoke River in which lay the Confederate ironclad "Albemarle." Cushing found her surrounded by logs but charging this barricade he got the launch partly over, immersed his spar, and exploded the charge in contact with the hull under heavy fire Ship and launch sank together but the gallant officer jumped overboard, swam away and escaped. When numbers of small guns and searchlights were added to a ship's equipment to counter such attacks the odds against success became prohibitive.

Locomotive Torpedoes.—Attention next turned to giving motion to the torpedo and steering it as necessary from the shore, or from another vessel, by means of wires. Of this type were the Lay, Sims-Edison and Brennan torpedoes. The first two were electrically steered through a wire which trailed behind the torpedo. The Brennan torpedo travelled under water and was pro-

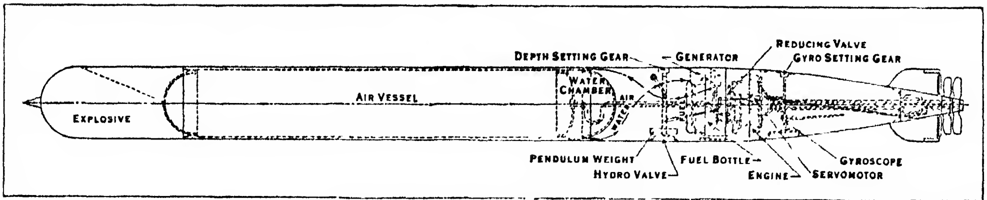


Diagram showing mechanism of a torpedo

pelled by unwinding two drums of fine steel wire inside the torpedo The rotation of these drums was communicated to propellers, causing the torpedo to advance, and it was steered by varying the speed of unwinding each wire. This torpedo was used for the defence of certain harbours by the British War Office The obvious unsuitability of this weapon for use by a ship during action led to the development of locomotive torpedoes of the uncontrolled type The Howell torpedo is of interest Motive power was provided by connecting up an engine outside to the axle of a heavy fly-wheel contained inside the torpedo When sufficiently spun up the engine was disconnected and the fly-wheel was connected up to the propellers so that on entering the water the torpedo was driven ahead until the energy was exhausted

In 1862 Captain Luppis of the Austrian Navy sought the assistance of Robert Whitehead, a Scotsman (then manager of an engineering factory at Fiume) to perfect a self-propelling floating torpedo which he had designed Mr. Whitehead modified this first suggestion and after two years of incessant labour the first Luppis-Whitehead torpedo was produced To preserve secrecy it was made by Mr Whitehead himself, his son and one trusted workman The torpedo weighed 300 lb travelled under the water, and a speed of 6 m per hour was attained for a short distance, the engine being driven by compressed air contained in a portion of the torpedo The charge carried was 18 lb of dynamite As the Austrian government were not prepared to purchase the exclusive rights of this invention it was offered to other powers From this beginning developed the modern weapon which, in its latest types, is capable of speeds up to 36 m per hour for 7,000–8,000 yd and carries an explosive charge of 500 lb of T N T The early lack of speed was overcome by the adoption of an engine designed by the British firm of Brotherhood. The inaccuracy in direction was cured by the introduction of the gyroscope apparatus designed by Ludwig Obry, an Austrian subject.

Construction.—The modern torpedo is a cigar shaped body, the diameter being usually about one-twelfth of the length, the diameter has grown from 14 in. in early types to 21 in in the latest types Generally it is divided into six compartments viz head, airvessel, balance chamber, engine room, buoyancy chamber and tail

The British 21 inch Mark IV. torpedo is briefly described below as a typical modern torpedo (*See* diagrammatic sketch above)

Head.—Three types are made. (1) The *warhead* is a thin steel or bronze shell containing 500 lb of T.N.T which is detonated on contact by a device, called a pistol, screwed into the nose (2) The *blowing head,* used for ordinary practice running, is a steel shell filled with water to make it of the same weight as a warhead and containing a flask of compressed air and the necessary mechanism for blowing the water out at the end of a run so making the torpedo buoyant and enabling it to be recovered (3) The *collision head,* used for practice when it is desired to hit a target vessel, is a steel shell partially filled with cork to give buoyancy and brought up to war head weight by filling with water. On impact with target the fore end collapses thus cushioning the blow on target and torpedo. An indicating light of calcium phosphide is fitted in a pocket to facilitate recovery. These heads are secured by screws to the *airvessel* which is made of special forged nickel steel and contains air compressed to 2,500 lb per sq.in. This air provides the oxygen for combustion of the fuel supplying the motive power. The *Balance Chamber* is a watertight compartment, with thin steel shell, permanently attached to the air vessel and contains the flasks of fuel and water and the heater apparatus Fuel and air are burnt in the generator and turn the water into steam there. The steam and products of combustion thus formed pass to the engine, combining to provide the motive power In this compartment, also, is the depth keeping mechanism which consists of a pendulum weight so interlinked with a hydrostatic valve that the weight corrects departure from the horizontal, whilst the valve maintains the set depth, their joint action operating the horizontal rudders through the medium of a small air engine termed the servomotor This combination was one of Robert Whitehead's principal secrets and was responsible for much of the success of his design

The *engine room* is the next compartment abaft the balance chamber and together with the buoyancy chamber, to which it is permanently attached, forms what is known as the afterbody This afterbody is secured to the balance chamber by a number of screwed bolts which allow of the torpedo being parted for examination of mechanism in the engine room The engine room contains (a) an engine of the four cylinder, single acting, Brotherhood type, (b) the steering engine or servomotor; (c) the starting valve and counter gear, (d) the reducing valve which maintains an approximately constant working pressure at the engine irrespective of air vessel pressure, (e) oil bottles for lubricating working parts, (f) sinking valve The starting valve is operated by the "air lever" which projects through the shell of the torpedo and is thrown aft on discharge by a downward projecting bolt in the torpedo tube In addition to opening the starting valve the air lever releases the gyroscope The counter is a piece of mechanism, driven off the engine, for stopping the torpedo at a definite range, or permitting it to run away Off the counter is driven the ignition gear, whose function is to fire the igniters in the generator at a predetermined moment and start the combustion of air and fuel The torpedo can be set to float for practice or to sink for action; in the latter case a small valve is lifted at the end of the run admitting water to the buoyancy chamber, thus sinking the torpedo which might otherwise remain a floating mine

The *buoyancy chamber* provides a large portion of the buoyancy of the torpedo It consists of thin sheet steel, strengthened up internally to enable it to withstand impulse pressure on discharge, or immersion at great depth The engine is secured to the foremost bulkhead of this compartment, and two watertight tubes run through it, one carrying the propeller shaft and the other carrying a rod connecting the servomotor and horizontal rudders The gyroscope is fixed to suitable brackets in this compartment, and connected to the vertical rudders. This piece of mechanism is a comparatively heavy bronze wheel mounted horizontally and vertically in gimbals When the air lever is thrown aft, the wheel is spun up to a high rate of revolution, due to the release of a strong spiral spring in torsion, or by air jets playing into pockets formed in the rim of the wheel At the same time the whole system is freed from external constraint, and, following the dynamical laws of rotating bodies, the spinning axis tends to maintain its direction in space Thus the axis of the spinning wheel provides a datum line, the direction of the gyro wheel on release Subsequent deviations of the torpedo are corrected by the relative movements of the spinning axis and the fore and aft line of the torpedo. These relative movements control the air supply to a small steering engine which operates vertical rudders, always acting to bring the torpedo back to its original direction. The gyroscope can be set at an angle to the axis of the torpedo when

required. In this case the torpedo turns through this angle before commencing its straight course The *tail* carries the horizontal and vertical rudders which are mounted on corresponding fins; it also contains gearing to enable two four-bladed propellers to be driven in opposite directions off the engine shaft and this ensures that the torpedo keeps its upright condition without heel, the turning effect of one propeller being balanced by the other.

Torpedo Discharge.—The earliest method of discharging Whitehead torpedoes from ships was by sliding them off a gunport, this naturally caused inaccuracy of direction Later the torpedo was put in a skeleton frame opposite an aperture specially cut in the vessel's side and was pushed out by a ram pressing on its tail Then the air gun was introduced and later the powder and cordite guns. In these the torpedo fits closely in a tube whose rear end can be closed by a gas-tight door. When it is desired to fire the torpedo, air or the gas from the powder or cordite charge is admitted to the rear end of the tube and blows the torpedo out Above water tubes of these types are fitted in all torpedo-craft and many cruisers. The danger of the torpedo's head being detonated, or air vessel burst, by hostile shell fire is accepted for these vessels To avoid this danger systems of under water discharge were devised. Right ahead or right astern fire offered little difficulty and was employed from the earliest days of torpedo development The torpedo tube is secured to the stem or stern structure in which an orifice is formed This orifice can be closed by a water-tight door and then the rear door can be opened and the torpedo placed in the tube. The rear door is then closed and the outer door opened. On firing, air pressure is admitted and blows the torpedo and water together out of the tube. Tubes in submarines are of this type. Without angled gyroscopes right ahead or right astern fire was of very limited value in large ships and consequently broadside discharge was required The difficulty was to get the torpedo clear of the ship undamaged as the water rushing past the tube orifice acts on the head as it emerges tends to force it aft and the torpedo is liable to be damaged It must, therefore, be held rigidly till its tail is clear of the ship's side. This is accomplished by pushing out a shield bar on the fore side of the tube to which the torpedo hooks itself by brackets working in grooves in the shield bar.

Torpedoes are also discharged from aircraft. Here they are secured to the under side of the fuselage by securing straps fitted with quick release gear. To fire, these straps are released together and at the same time the air lever is pulled aft to start the engines and the torpedo drops with the forward speed of the aeroplane instead of speed due to impulse from a tube.

Use of the Locomotive Torpedo in Action.—Owing to the comparatively slow speed of the torpedo it must be aimed at a point ahead of the ship attacked which will be reached by ship and torpedo after they have travelled a certain distance In order to obtain a hit the speed and course of the attacked vessel must, therefore, be estimated correctly, also the speed of the torpedo must be regular and accurate within narrow limits. Owing to the difficulty of exact estimation it is usually considered that torpedo fire at a single ship free to alter course is only justified at short ranges and that long range attacks should be confined to cases where a group of ships forms the target Prior to the World War of 1914–18 the occasions of torpedo attacks were few. On April 23, 1891 at dawn the Chilean insurgent battleship "Blanco Encalada," 3,500 tons, was attacked while at anchor and was sunk by one torpedo fired from a Government torpedo gunboat Again on April 5, 1894 the insurgent Brazilian battleship "Aquidaban" was sunk by one torpedo from a torpedo vessel. In the Chino-Japanese war of 1895 Japanese torpedo boats twice attacked the Chinese ships lying in Wei-Hai-Wei harbour and sank four of them. In the Russo-Japanese war, the initial success on February 8, 1904 was scored by Japan with a torpedo attack on the Russian ships at Port Arthur. Three ships were severely damaged although all were eventually repaired. After the battle of Tsushima, Japanese torpedo craft gave the *coup-de-grace* to several partially disabled ships.

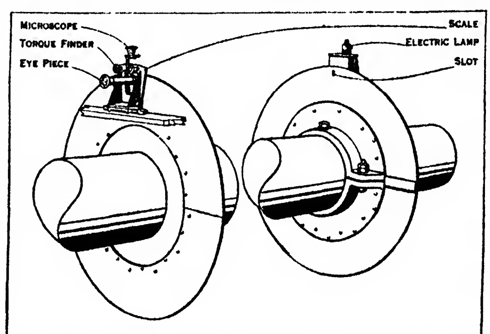
The advent of the submarine gave a new impetus to torpedo warfare as the submarine was the ideal carrier of this weapon owing to its ability to approach unseen within close range of its intended victim. If the victim is a slow ship the submarine has little difficulty in attaining the desired position but with fast moving vessels this becomes difficult and it is only when the ship is steaming more or less towards the submarine's initial position that the latter has much chance of success. The normal speed of the tramp cargo steamer rendered her peculiarly liable to attack in the World War of 1914–18, and of British merchant vessels some 1,381 were sunk by this weapon alone. The best defence against torpedo attack by submarine is high speed and a zig-zag course (*See* also SUBMARINE CAMPAIGN.)

At the battle of Jutland (*q.v*) May 31, 1916, concentrated attacks by groups of torpedo craft were delivered by both British and German fleets but comparatively few hits were obtained During the night following the battle the British Twelfth Flotilla, commanded by Captain A. J. B. Stirling, made a deliberate attack on the German Second Squadron and sank the pre-Dreadnought battleship "Pommern." The British Fourth Flotilla fell in with German cruisers; the "Rostock" was torpedoed and in the confusion of the action the "Elbing" collided with a battleship Both "Rostock" and "Elbing" were later abandoned and sunk A successful attack with torpedoes was carried out by British coastal motor boats upon the Bolshevist ships lying at Kronstadt in September 1919, four ships being hit. (A. H W.)

TORQUAY, a municipal borough, seaport and watering place, in the Torquay parliamentary division of Devon, England, on Tor bay of the English channel, 26 m S of Exeter, by the G W railway Pop (1921) 39,431 Owing to the beauty of its site and the equability of its climate, it has high repute as a winter resort There are some remains of Tor or Torre abbey, founded for Praemonstratensians by William, Lord Brewer, in 1196, including a beautiful pointed arch portal. On the south of the gateway is a 13th-century building, known as the Spanish barn. On Chapel hill are the remains of a chapel of the 12th century, dedicated to St. Michael, and supposed to have formerly belonged to the abbey.

There was a village at Torre even before the foundation of the abbey, and in the neighbourhood of Torre evidence has been found of Roman occupation The manor was granted by William the Conqueror to Richard de Bruvere or de Brewere, and was subsequently known as Tor Brewer. After the defeat of the Spanish Armada, Don Pedro's galley was brought into Torbay; and William, prince of Orange, landed at Torbay on Nov. 5, 1688.

TORQUE, the twist or torsion which a shaft undergoes when transmitting power. The degree of twist is very slight,



CHADBURN FLASHLIGHT TORSION METER, WHICH MEASURES THE HORSE POWER TRANSMITTED BY A TURBINE SHAFT

but it can be measured and the horse-power that is transmitted can thus be ascertained, the method being applied particularly to steam turbines. There are several types of torsion-meters for measuring horse-power, electrical, mechanical and flash-light. One of the last-named type is here described; its principle depends primarily on the straightness and great speed of a ray of light. Two discs (*see* fig.) are fastened to the shaft a measured

distance apart. Each disc has a small slit in it, about ¼ in. by ⅛ in., and a lamp is attached near one disc by a rigid support; the torque-finder is also rigidly secured. The light from the lamp is limited by a slit of similar size to those in the discs, and the torque-finder comprises a casting with a small telescopic eyepiece screwed to a brass plate which also has a slit of the same size as the others The plate and eyepiece can be moved circumferentially by means of a micrometer apparatus, reading to ·01 of a degree If the lamp, discs and torque-finder are set so that the four slits are in line, the observer looking through the eyepiece parallel to the axis of the shaft will see the light shining in the lamp If the shaft starts to revolve, at each rotation as the two slits in the discs pass the sight line between lamp and finder the light will be seen momentarily The persistence of this flash with the rapidly revolving shaft makes it appear as a continuous light. When however the shaft commences to transmit power the torque throws the disc slits out of line and the light is obscured The observer now adjusts the micrometer and the eyepiece until a sight is again taken through the disc slits By noting the amount of the displacement thus made the degree of twist is measured, and therefrom the horse-power transmitted *See* DYNAMOMETER (F H)

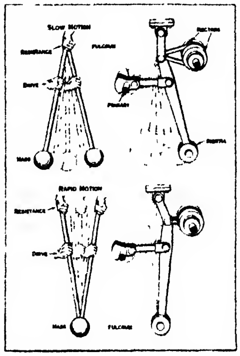
TORQUE AMPLIFIER. The torque amplifier consists of a mechanism provided with a control-shaft at one end and a work-shaft at the other, the control-shaft requiring only a feeble torque to operate it in either direction, while the work-shaft yields a torque of sufficient amount to accomplish any purpose desired, at the same time accurately following the control-shaft in all its angular movements Its broad purpose is to perform the functions of an electrical or hydraulic servo-motor

The torque amplifier was invented by Henry W. Nieman, an engineer for the Bethlehem Steel Co It was originally developed for the control of anti-aircraft gun batteries from a remote control station The torque amplifier has three elements: "work-shaft," "control-shaft" and "drive-shaft" The drive-shaft is driven by any outside source of power, and revolves continuously in one direction The control-shaft is actuated by any mechanical or manual control means, or by such weak forces as can be delivered through electrical recording instruments or telemetric transmission systems The work-shaft is directly coupled to the work to be done, as for instance the elevating or training gears of a gun, a ship's rudder or the steering gear of an automobile The control-shaft can be freely revolved in either direction, with only a small amount of effort; the work-shaft maintains at all times its angular synchronism with the control-shaft, and in addition exerts a heavy torque to overcome outside resistance Unlike other forms of servo-motor, there is always a definite ratio between the torque applied at the control-shaft and that delivered at the work-shaft, this ratio being known as the "amplification"

Fundamentally, the torque amplifier consists of two oppositely rotating drums provided with friction bands which may be brought into contact with the drums through actuation of the control-shaft, this frictional contact causing the friction bands to exert pressure on the work-shaft. The force applied to the control-shaft is thus enhanced, or amplified, when it reaches the work-shaft by the extent to which the bands are urged forward because of their frictional contact with the rotating drums.

TORQUE CONVERTER is an apparatus for transmitting power automatically from an engine or other source of power to a secondary shaft, the torque and speed of the secondary being variable according to the load between wide limits It was invented by George Constantinesco. The principle of the torque converter consists in dividing an oscillatory movement derived from a primary shaft which is driven by the engine, into two component oscillatory motions of the same frequency. One of these components oscillates an inertia device and the other oscillates unidirectional driving devices mounted on the secondary. The alternating impulses received by the secondary through the unidirectional devices are thus rectified into continuous rotation of the secondary.

Such unidirectional driving devices, shortly named "rectors," comprise any such devices which will drive in one direction and be free in the opposite direction. The rectors perform what may be termed a "mechanical valve" action very much like an ordinary hydraulic valve or electric valve, or rectifiers allowing the flow of energy only in one direction The left hand figures of each of the two pairs of illustrations, depict two phases of an experiment which will illustrate the principle of the torque converter The operations performed by each hand are then translated in the right hand figures into the functions of a "torque converter" in which the lower hand is replaced by a connecting rod moved by a crank, and the upper hand by two rectors which are connected to the secondary shaft where the resistance occurs



A slow oscillatory motion at the "drive" merely swings the mass to and fro, the fulcrum of oscillation remaining at the point of resistance If a rapid oscillatory motion is applied at the "drive" the inertia of the mass will oppose its motion, and the resistance is overcome The upper hand moves then, almost as if it were driven directly, the fulcrum being right down at the mass Such a combination is a four dimensional mechanism as the element "time" is essential to its performance The ordinary rules of static mechanics do not apply to the torque converter, and it is only by the consideration of the elements "time" and "mass" that the behaviour of the converter can be explained.

The torque converter has many possible applications to traction problems and industry in general as in transmission for applying the power of internal combustion engines, turbines, electromotors and prime movers which lack flexibility, to uses where wide and unexpected fluctuations in the load occurs The torque converter provides automatically for the adjustment of the speed and torque on the secondary, no matter how the resistance changes or fluctuates between very wide limits, while the prime mover continues to run steadily, with very little variation, at its most efficient torque and speed. In practice the inertia systems and the rectors are so arranged that the various parts balance each other dynamically as much as possible so that no vibrations are imparted on the casting of the machine

A petrol (gasolene) engine may be combined with mechanism so as to form one single unit; the only control required being the throttle of the engine Vehicles driven by such units have no clutches nor gear change boxes By opening wide the throttle of the engine the vehicle will accelerate from rest and attain a certain maximum speed on the level. When a hill is encountered, the vehicle slows down while the tractive force increases automatically according to the gradient For example, a vehicle fitted with a torque converter may travel at 40 m per hour on a level or climb at 10 m per hour a gradient of one in four, while the torque and the speed of the engine remains the same in both cases.

TORQUEMADA, JUAN DE (1388–1468), or rather JOHANNES DE TURRECREMATA, Spanish ecclesiastic, was born at Valladolid, in 1388, and was educated in that city. At an early age he joined the Dominican order, and soon distinguished himself for learning and devotion. In 1415 he accompanied the general of his order to the Council of Constance, whence he proceeded to Paris for study, and took his doctorate in 1423 In 1431 Eugenius IV. called him to Rome and made him "magister sancti palatii." At the Council of Basel he was one of the ablest supporters of the view of the Roman curia, and he was rewarded with a cardinal's hat in 1439 He died at Rome Sept 26, 1468

His principal works are *In Gratiani Decretum commentarii* (4 vols., Venice, 1578), *Expositio brevis et utilis super toto psalterio* (Mainz, 1474); *Quaestiones spirituales super evangelia totius anni* (Brixen, 1498); *Summa ecclesiastica* (Salamanca, 1550). The last named work has the following topics: (1) De universa ecclesia; (2) De Ecclesia romana et pontificis primatu; (3) De universalibus conciliis, (4) De

schismaticis et haereticis. His *De conceptione deiparae Mariae, libri viii* (Rome, 1547), was edited with preface and notes by E. B. Pusey (London, 1869 *seq.*).

TORQUEMADA, THOMAS (1420–1498), inquisitor-general of Spain, son of Don Pedro Ferdinando, lord of Torquemada, a small town in Old Castile, was born in 1420 at Valladolid during the reign of John II He was a nephew of the cardinal noticed above, and joined the Friars Preachers in their convent at Valladolid. His superiors obliged him to take the priorship of the convent of Santa Cruz in Segovia, where he ruled for 22 years The royal family, especially the queen and the infanta Isabella, often stayed at Segovia, and Torquemada became confessor to the infanta, who was then very young He trained her to look on her future sovereignty as an engagement to make religion respected He then began to teach her the political advantages of religion and to prepare the way for the Inquisition.

When Isabella succeeded to the throne (1474), she entrusted Torquemada with the care of her conscience, and with the benefices in the royal patronage. He also became confessor to Ferdinand and was appointed councillor of state also In the lax toleration of religious differences he thought he saw the main obstacle to the political union of the Spains. He represented to Ferdinand and Isabella that it was essential to their safety to reorganize the Inquisition, which had since the 13th century (1236) been established in Spain. In 1473 Torquemada and Gonzalez de Mendoza, archbishop of Toledo, approached the sovereigns. Isabella and Ferdinand saw in the proposed new tribunal a means of overcoming the independence of the nobility and clergy by which the royal power had been obstructed In 1479, as the result of a long intrigue, a papal bull authorized the appointment by the Spanish sovereigns of two inquisitors at Seville, under whom the Dominican inquisitions already established elsewhere might serve In the persecuting activity that ensued the Dominicans, "the Dogs of the Lord" (*Domini canes*), took the lead. The royal Inquisition thus started was subversive of the regular tribunals of the bishops, who much resented the innovation, which, however, had the power of the state at its back.

The Inquisition.—In 1481, three years after the Sixtine commission, a tribunal was inaugurated at Seville, where freedom of speech and licence of manner were rife The inquisitors at once began to detect errors In order not to confound the innocent with the guilty, Torquemada published a declaration offering grace and pardon to all who presented themselves before the tribunal and avowed their fault Some fled the country, but many (Mariana says 17,000) offered themselves for reconciliation The first seat of the Holy Office was in the convent of San Pablo, where the friars, however, resented the orders, on the pretext that they were not delegates of the inquisitor-general Soon the gloomy fortress of Triana, on the opposite bank of the Guadalquivir, was prepared as its palace. Other tribunals were speedily established in Cordova, Jaen and Toledo The sovereigns obliged Torquemada to take as assessors five persons who would represent them in all matters affecting the royal prerogatives. These assessors were allowed a definite vote in temporal matters but not in spiritual, and the final decision was reserved to Torquemada himself, who in 1483 was appointed the sole inquisitor-general over all the Spanish possessions. In the next year he ceded to Diego Deza, a Dominican, his office of confessor to the sovereigns, and gave himself up to the work of reducing heretics

A general assembly of his inquisitors was convoked at Seville in November 1484, and there he promulgated a code of twenty-eight articles for the guidance of the ministers of the faith. For the procedure adopted *see* INQUISITION. During the 18 years that Torquemada was inquisitor-general it is said that he burnt 10,220 persons, condemned 6,860 others to be burnt in effigy, and reconciled 97,321, thus making an average of some 6,000 convictions a year. These figures are given by Llorente, who was secretary of the Holy Office from 1790 to 1792 and had access to the archives; but modern research reduces the list of those burnt by Torquemada to 2,000 The constant stream of petitions to Rome opened the eyes of the pope to the effects of Torquemada's severity. On three separate occasions he had to send Fray Alfonso Badaja to defend his acts before the Holy See. The sovereigns, too, saw the stream of money, which they had hoped for, diverted to the coffers of the Holy Office, and in 1493 and again in 1496 they made complaint to the pope.

Torquemada had urged Ferdinand and Isabella to rid the country of the Moors, and, when war began in 1481, he obtained from the Holy See the same spiritual favours for the Spanish soldiers as had been enjoyed by the Crusaders The Inquisition sometimes met with furious opposition from the nobles and common people At Valentia and Lerida there were serious conflicts At Saragossa Peter Arbuè, a canon and an ardent inquisitor, was slain in 1485 whilst praying in a church, and the threats against the hated Torquemada made him go in fear of his life, and he never went abroad without an escort of forty familiars of the Holy Office on horseback and two hundred more on foot. In 1487 he went with Ferdinand to Malaga and thence to Valladolid, where in the October of 1488 he held another general congregation of the Inquisition and promulgated new laws based on the experience already gained He then hurried back to Andalusia where he joined the sovereigns, who were now besieging Granada

Persecution of Jews.—The Moors being vanquished, now came the turn of the Jews For long before 1490 Torquemada had tried to get the royal consent to a general expulsion; but the sovereigns hesitated, and, as the victims were the backbone of the commerce of the country, proposed a ransom of 300,000 ducats instead The indignant friar would hear of no compromise· "Judas," he cried, "sold Christ for 30 pence; and your highnesses wish to sell Him again for 300,000 ducats" Unable to bear up against the Dominican's fiery denunciations, the sovereigns, three months after the fall of Granada, issued a decree ordering every Jew either to embrace Christianity or to leave the country.

The inquisitor-general issued orders to forbid Christians, under severe penalties, having any communication with the Jews or, after the period of grace, to supply them even with the necessaries of life The former prohibition made it impossible for the unfortunate people to sell their goods which hence fell to the Inquisition The numbers of Jewish families driven out of the country by Torquemada is variously stated from Mariana's 1,700,000 to the more probable 800,000 of later historians The loss to Spain was enormous, and from this act of the Dominican the commercial decay of Spain dates

Torquemada at length took up his residence in Avila, where he had built a convent; and here he resumed the common life of a friar, leaving his cell in October 1497 to visit, at Salamanca, the dying infante, Don Juan, and to comfort the sovereigns in their parental distress. They often used to visit him at Avila, where in 1498, still in office as inquisitor-general, he held his last general assembly to complete his life's work. Torquemada died on Sept. 16, 1498

TORRE, CARLOS DE LA (1858–), Cuban naturalist, teacher, author, was born in Matanzas, Cuba, May 15, 1858 Receiving his education in Havana and Madrid, he had, before he was 21, discovered two new species of mollusc, which were named in his honour *Cylindrella torrei*, Arango, 1876, and *Cyclostoma torreianum*, Gundlach, 1878. He was one of the founders of the School of Arts and Crafts in Havana, taught at the Institute of Havana and in 1884 was appointed to fill the professorships of comparative anatomy and zoography of molluscs and zoophytes in the University of Havana. At the outbreak of the Cuban War for Independence (1895) persecutions of the Spanish government led him to leave the country, and after a brief visit in Mexico he went to Paris to study, where in 1897 he was elected to the Société Zoologique of France. Upon his return to Cuba in 1898 he resumed his career at the university, and entered political life. He was active in founding and organizing the nationalist party which came into power in 1902, under which he held numerous public offices, as he had done under its predecessor, the Government of the American intervention, and when, in 1899, the Cuban public school system was organized, he was an eager collaborator and prepared several of the necessary text-books. In 1909 he proved

the existence of Jurassic strata in the western part of Cuba and in 1910 he discovered Pleistocene fossils, restoring a *Megalocnus rodens*, discoveries "which have revolutionized the geological history of Cuba"

See W B. Parker, *Cubans of To-Day* (New York, 1919)

TORRE ANNUNZIATA, a seaport of Campania, Italy, in the province of Naples, on the east of the Bay of Naples, and at the south foot of Mt Vesuvius, 14 m S E of Naples by rail. Pop (1921), 32,159. town; 32,570, commune It is on the main line to Battipaglia, at the point of junction of a branch line from Cancello round the east of Vesuvius, and of the branch to Castellammare di Stabia and Gragnano It has an arms factory and other ironworks, manufacture of macaroni and breeding of silkworms There are numerous mineral springs

TORRE DEL GRECO, a seaport of Campania, Italy, in the province of Naples, 7½ m S E of that city by rail Pop (1921), 33,915. town; 45,641. commune It lies at the south-west foot of Vesuvius, on the shore of the Bay of Naples. It is built chiefly of lava, and stands on the lava stream of 1631, which destroyed two-thirds of the older town Great damage was done by the eruptions of 1737 and 1794, the earthquake of 1857 and the eruption of Dec. 8, 1861, were even more destructive

TORRENS, ROBERT (1780–1864), English soldier and economist, was born in Ireland in 1780 He entered the Marines in 1797, became a captain in 1806, and major for bravery at Anhalt in 1811 He fought in the Peninsula, becoming lieutenant-colonel in 1835 and retiring as colonel in 1837 He was returned to parliament in 1831 as member for Ashburton He was a prolific writer, principally on financial and commercial policy Almost the whole of the programme which was carried out in legislation by Sir Robert Peel had been laid down in his economic writings He was an early advocate of the repeal of the corn laws

His principal writings of a general character were *The Economist [i e., Physiocrat] refuted* (1808), *Essay on the Production of Wealth* (1821), *Essay on the External Corn-trade* (eulogized by Ricardo) (1827), *The Budget, a series of Letters on Financial, Commercial and Colonial Policy* (1841–1843), *The Principles and Practical Operations of Sir Robert Peel's Act of 1844 Explained and Defended* (1847)

TORRENS, WILLIAM TORRENS M'CULLAGH (1813–1894), English politician and social reformer, son of James M'Cullagh, was born near Dublin on Oct 13, 1813 He was called to the bar, and in 1835 became assistant commissioner on the special commission on Irish poor-relief, which resulted in the extension of the workhouse system in Ireland in 1838 In the 'forties he joined the Anti-Corn Law League, and in 1846 published his *Industrial History of Free Nations* From 1847–52 he represented Dundalk in parliament, in 1857 he was returned for Yarmouth, and from 1865–85 he represented Finsbury Torrens devoted himself mainly to social questions in parliament His amendment to the Education Bill of 1870 established the London School Board, and his Artisans' Dwellings Bill in 1868 facilitated the clearing away of slums by local authorities. He published several books, and his *Twenty Years in Parliament* (1893) and *History of Cabinets* (1894) contain useful material. He died in London on April 26, 1894.

TORRENS, LAKE: *see* SOUTH AUSTRALIA

TORRES VEDRAS, 43 m. N by W of Lisbon, on the Lisbon-Figueira da Foz railway Pop. (1911), 7,911. Roman inscriptions have been found here, but the Latin name of the town, *Turres Veteres*, is probably mediaeval Here were "lines of Torres Vedras," constructed by Wellington in 1810 (*see* PENINSULAR WAR). Here also in 1846 the troops of General Saldanha defeated those of the count de Bomfim (*See* PORTUGAL. *History.*)

TORREVIEJA, a seaport of south-eastern Spain, in the province of Alicante, 3 m S.W. of Cape Cervera, and at the terminus of a railway to Albatera on the Alicante-Murcia line. Pop. (1920), 8,885. The district is famous for its salt beds, which are owned by the state which farms them out for £10,000 a year, the Laguna Grande alone yielding more than 100,000 tons a year.

TORREY, JOHN (1796–1873), American botanist, was born in New York city on Aug. 15, 1796. He graduated (M.D.) in 1818 from the College of Physicians and Surgeons in New York. After holding various positions he became in 1836 New York State botanist and produced his *Flora of the State of New York* in 1843; while from 1838 to 1843 he carried on the publication of the earlier portions of *Flora of North America*, with the assistance of his pupil, Asa Gray From 1853 he was chief assayer to the U S. assay office, but he continued to take an interest in botanical teaching until his death at New York on March 10, 1873 He gave his valuable herbarium and botanical library to Columbia college

TORRICELLI, EVANGELISTA (1608–1647), Italian physicist and mathematician, was born at Faenza on Oct. 15, 1608 In 1627 he went to Rome to study science under the Benedictine Benedetto Castelli (1577–1644), professor of mathematics at the Collegio di Sapienza The perusal of Galileo's *Dialoghi delle nuove scienze* (1638) inspired him with many developments of the mechanical principles there set forth, which he embodied in a treatise *De motu* (printed amongst his *Opera geometrica*, 1644). In 1641 he went to Florence, where he met Galileo, and acted as his amanuensis during the three remaining months of his life After Galileo's death Torricelli was nominated grand-ducal mathematician and professor of mathematics in the Florentine academy. The discovery of the principle of the barometer (*q v.*) which has perpetuated his fame ("Torricellian tube" "Torricellian vacuum") was made in 1643 Torricelli was brought into controversy with G. P de Roberval as to the priority of the solution of a problem on the properties of a cycloid He died at Florence on Oct 25, 1647

Torricelli wrote on fluid motion, on the theory of projectiles and on the motion of two bodies connected by a string passing over a fixed pulley He used and developed B Cavalieri's method of indivisibles

TORRIGIANO, PIETRO (1472–1522), Florentine sculptor, was one of the group of talented youths who studied art under the patronage of Lorenzo the Magnificent in Florence. Torrigiano was invited to England to execute the tomb for Henry VII and his queen, in Westminster Abbey After this Torrigiano received the commission for the altar retable and baldacchino which stood at the west outside the screen of Henry VII 's tomb This work was destroyed by the Puritans in the 17th century Henry VIII also commissioned Torrigiano to make a magnificent tomb, somewhat similar to that of Henry VII, to be placed in a chapel at Windsor; it was, however never completed, and its rich bronze was melted by the Commonwealth The indentures for these various works still exist, and are printed by Neale, *Westminster Abbey*, i 54–59 (1818) The Tomb of Margaret of Richmond in Westminster Abbey is ascribed to Torrigiano. He ended his life in 1522 in the prisons of the Inquisition

See Wilhelm Bode, *Die italienische Plastik* (1902)

TORRINGTON, ARTHUR HERBERT, EARL OF (1647–1716), British admiral was the son of a judge, Sir Edward Herbert (*c* 1591–1657) He entered the navy in 1663, and served in the Dutch wars of the reign of Charles II, as well as against the Barbary pirates From 1680 to 1683 he commanded in the Mediterranean. The known Royalist sentiments of his family and his reputation as a naval officer ensured the favour of James II, who appointed him rear-admiral of England and master of the robes But Herbert refused to support the king's proposal for the repeal of the Test Act, and was dismissed from his places. He now entered into communication with the agents of the prince of Orange After the acquittal of the seven bishops in 1688 he carried the invitation to William of Orange After the Revolution Herbert was named first lord of the admiralty, and took the command of the fleet at home In 1689 he was at sea attempting to present the French admiral Château-Renault (*q v*) from landing the troops sent by the king of France to the aid of King James in Ireland Though he fought an action with the French in Bantry Bay on May 10 he failed to baffle Château-Renault, who had a stronger force. In May 1689 he was created earl of Torrington. In 1690 he was in the Channel with a fleet of 56 English and Dutch vessels, when he found himself confronted with the much more powerful French fleet. He proposed to retire to the Thames, but the council of regency, knowing that the Jacobites were preparing for a rising, and only waiting for the support

of a body of French troops, ordered him not to lose sight of the enemy, but rather than do that to give battle "upon any advantage of the wind." On July 10 Torrington made a half-hearted attack on the French off Beachy Head in which his own ship was kept out of fire, and severe loss fell on his allies Then he retired to the Thames. The French pursuit was fortunately feeble, and the loss of the allies was comparatively slight. Torrington was brought to trial before a court martial in December, and acquitted. He died on April 14, 1716

The unfavourable account of his moral character reported by Dartmouth to Pepys is confirmed by Bishop Burnet, who had seen much of him during his exile in Holland Torrington originated the phrase "a fleet in being"

See Charnock's *Biog. Nav*, i. 258 The best account of the battle of Beachy Head is to be found in "The Account given by Sir John Ashby Vice-Admiral and Rear-Admiral Rooke, to the Lords Commissioners" (1691).

TORRINGTON, GEORGE BYNG, VISCOUNT (1663–1733), English admiral, was born at Wrotham, Kent, and entered the navy in 1678. In 1688 he helped to win the fleet over to the prince of Orange, appointed to the command of the "Nassau" in 1702 he was present at the burning of the French fleet at Vigo, and in 1703 was made rear-admiral of the red. He served in the Mediterranean (1704) and at the battle of Malaga, after which he was knighted. In 1708, as admiral of the blue he prevented the Old Pretender from landing in Scotland; and ten years later defeated the Spaniards off Passaro, after which the king sent him full powers to negotiate with the princes and States of Italy. To his conduct it was owing that Sicily was subdued and the king of Spain forced to accept the terms prescribed by the Quadruple alliance. On his return to England in 1721 he was made rear-admiral and a member of the privy council, and was created Baron Byng of Southill in Bedfordshire, Viscount Torrington in Devonshire and a Knight Companion of the Bath (1725) George II. made him first lord of the Admiralty in 1727 He died on Jan 17, 1733

See *Memoirs relating to Lord Torrington*, Camden Soc new series 46, and *A True Account of the Expedition of the British Fleet to Sicily, 1718–1720*, published anonymously, but known to be by Thomas Corbett of the Admiralty in 1739. Forbin's *Memoirs* contain the French side of the expedition to Scotland in 1708

TORRINGTON (GREAT TORRINGTON), a market town and municipal borough in the South Molton parliamentary division of Devon, England, on the Torridge, 225 m W. by S of London by the S. railway. Pop (1921) 2,929.

Torrington was the site of very early settlement, and possessed a market in Saxon times. In the 16th century it was an important centre of the clothing trade. In 1643 Colonel Digby took up his position at Torrington and put to flight a contingent of Parliamentary troops; but in 1646 the town was besieged by Sir Thomas Fairfax and finally forced to surrender

See *Victoria County History: Devonshire;* F T Colby, *History of Great Torrington* (1878).

TORRINGTON, a city of Litchfield county, Connecticut, U.S.A., on the Naugatuck river, 25 m W. of Hartford It is served by the New York, New Haven and Hartford railroad. Pop. (1920) 22,055 (about a third foreign-born white); 1928 local estimate 25,000. The city is surrounded by the beautiful scenery of the Berkshire foot-hills, with five lakes close by. Ever since brass kettles were first made here in 1834 it has been an important centre of the brass industry, and other products also are now manufactured in great variety The aggregate factory output in 1925 was valued at $26.341,064 In 1740 the town was incorporated. A woollen mill was built in 1813 by members of the Wolcott family, and the village which grew up around it was called Wolcottville. In 1881 it took the name of the town, and in 1887 was incorporated as a borough In 1923 the town (including the borough) was chartered as a city. In 1851 the first condensed-milk plant in the world was established here by Gail Borden.

TORSION BALANCE: *see* BALANCE.

TORSTENSSON, LENNART, COUNT (1603–1651), Swedish soldier, son of Torsten Lennartsson, commandant of Elfsborg, was born at Forstena in Vestergötland. At the age of 15 he became one of the pages of the young Gustavus Adolphus and served during the Prussian campaigns of 1628–29. In 1629 he was set over the Swedish artillery, and contributed to the victories of Breitenfeld (1631) and Lech (1632). The same year he was taken prisoner at Alte Veste and shut up for nearly a year at Ingolstadt Under Banér he rendered distinguished service at the battle of Wittstock (1636) and during the energetic defence of Pomerania in 1637–38, as well as at the battle of Chemnitz (1638) and in the raid into Bohemia in 1639. Illness compelled him to return to Sweden in 1641, when he was made a senator The sudden death of Banér in May 1641 recalled Torstensson to Germany as generalissimo of the Swedish forces and governor-general of Pomerania. He was at the same time promoted to the rank of field marshal The period of his command (1641–45) forms one of the most brilliant chapters in the military history of Sweden. In 1642 he marched through Brandenburg and Silesia into Moravia, taking all the principal fortresses on his way On returning through Saxony he well nigh annihilated the imperialist army at the second battle of Breitenfeld (Oct 23, 1642) In 1643 he invaded Moravia for the second time, but was suddenly recalled to invade Denmark, when his rapid and unexpected intervention paralysed the Danish defence on the land side, though Torstensson's own position in Jutland was for a time precarious owing to the skilful handling of the Danish fleet by Christian IV

In 1644 he led his army for the third time into the heart of Germany and routed the imperialists at Juterbog (Nov 23) At the beginning of Nov 1645 he broke into Bohemia, and the brilliant victory of Jankow (Feb 24, 1645) laid open before him the road to Vienna. Yet, though one end of the Danube bridge actually fell into his hands, his exhausted army was unable to penetrate any farther and, in December the same year, Torstensson, crippled by gout, was forced to resign his command and return to Sweden In 1647 he was created a count. From 1648 to 1651 he ruled all the western provinces of Sweden, as governor-general. On his death at Stockholm (April 7, 1651) he was buried solemnly in the Riddarholmskyrka, the Pantheon of Sweden. Torstensson was remarkable for the extraordinary and incalculable rapidity of his movements, though very frequently he had to lead the army in a litter as his bodily infirmities would not permit him to mount his horse He was also the most scientific artillery officer and the best engineer in the Swedish army

See J. W. de Peyster, *History of the Life of L Torstensson* (Poughkeepsie, 1855); J. Feil, *Torstensson before Vienna* (trans by de Peyster, New York, 1885); Gustavus III, *Eulogy of Torstensson* (trans. by de Peyster, New York, 1872) (R N B)

TORT, the technical term, in the law of England, of those dominions and possessions of the British empire where the common law has been received or practically adopted in civil affairs, and of the United States, for a civil wrong, *i e.*, the breach of a duty imposed by law, by which breach some person becomes entitled to sue for damages A tort must, on the one hand, be an act which violates a general duty The rule which it breaks must be one made by the law, not, as in the case of a mere breach of contract, a rule which the law protects because the parties have made it for themselves On the other hand, a tort is essentially the source of a private right of action An offence which is punishable, but for which no one can bring a civil action, is not a tort It is quite possible for one and the same act to be a tort and a breach of contract, or a tort and a crime; it is even possible in one class of cases for the plaintiff to have the option—for purposes of procedural advantage—of treating a real tort as a fictitious contract; but there is no necessary or general connection. Again, it is not the case that pecuniary damages are always or necessarily the only remedy for a tort; but the right to bring an action in common law jurisdiction, as distinct from equity, matrimonial or admiralty jurisdiction, with the consequent right to damages, is invariably present where a tort has been committed

This technical use of the French word *tort* (which at one time was near becoming a synonym of *wrong* in literary English) is not very ancient, and anything like systematic treatment of the subject as a whole is very modern. Since about the middle of the 19th century there has been a current assumption that all civil

causes of action must be founded on either contract or tort; but there is no historical foundation for this doctrine, though modified forms of the action of trespass—actions *in consimili casu*, or "on the case" in the accustomed English phrase—did in practice largely supplant other more archaic forms of action by reason of their greater convenience The old forms were designed as penal remedies for manifest breach of the peace or corruption of justice; and traces of the penal element remained in them long after the substance of the procedure had become private and merely civil The transition belongs to the general history of English law

In England the general scope of the law of torts has never been formulated by authority. But there is no doubt that the duties enforced by the English law of torts are broadly those which the Roman institutional writers summed up in the precept *Alterum non laedere*. Every member of a civilized commonwealth is entitled to require of others a certain amount of respect for his person, reputation and property, and a certain amount of care and caution when they go about undertakings attended with risk to their neighbours Under the modern law, it is submitted, the question arising when one man wilfully or recklessly harms another is not whether some technical form of action can be found in which he is liable, but whether he can justify or excuse himself. This view, at any rate, is countenanced by a judgment of the Supreme Court of the United States delivered in 1904

The precise amount of responsibility can be determined only by full consideration in each class of cases But what makes the law of torts effective, especially with regard to redress for harm suffered by negligence, is the universal rule of law that every one is answerable for the acts and defaults of his servants (that is, all persons acting under his direction and taking their orders from him or some one representing him) in the course of their employment The person actually in fault is not the less answerable, but the remedy against him is very commonly not worth pursuing But for this rule corporations could not be liable for any negligence of their servants, however disastrous to innocent persons, except so far as it might happen to constitute a breach of some express undertaking We have spoken of the rule as universal, but, in the case of one servant of the same employer being injured by the default of another, an unfortunate aberration of the courts, which started from small beginnings in the second quarter of the 19th century, was pushed to extreme results, and led to great hardship A partial remedy was applied in 1880 by the Employers' Liability Act, and in 1897 a much bolder step was taken by the Workmen's Compensation Act (superseded by later amendment and extension now consolidated in an Act of 1925). The Workmen's Compensation Act includes cases of pure accident, where there is no fault at all, or none that can be proved, and therefore goes beyond the reasons of liability with which the law of torts has to do In fact, it establishes a kind of compulsory insurance, justifiable only on wider grounds of policy

There are kinds of cases, on the other hand, in which the law, without aid from legislation, has imposed on occupiers and other persons in analogous positions a duty stricter than that of being answerable for themselves and their servants. Duties of this kind have been called "duties of insuring safety." Generally they extend to having the building, structure, or works in such order, having regard to the nature of the case, as not to create any unusual danger to persons lawfully frequenting, using or passing by them, which the occupier knows or ought to know and could prevent by reasonable care; but in some cases of "extra-hazardous" risk, even proof of all possible diligence—according to English authority, which is not unanimously accepted in America —will not suffice

Classification.—The classification of actionable wrongs is perplexing We may start either from the character of the defendant's act or omission, with regard to his knowledge, intention and otherwise; or from the character of the harm suffered by the plaintiff Whichever of these we take as the primary line of distinction, the results can seldom be worked out without calling in the other. Taking first the defendant's position, the widest governing principle is that, apart from various recognized grounds of immunity, a man is answerable for the "natural and probable" consequences of his acts; *i e*, such consequences as a reasonable man in his place should have forseen as probable Still more is he answerable for what he did actually forsee and intend Knowledge of particular facts may be necessary to make particular kinds of conduct wrongful Such is the rule in the case of fraud and other allied wrongs, including what is rather unhappily called "slander of title," and what is now known as "unfair competition" in the matter of trade names and descriptions, short of actual piracy of trade-marks But where an absolute right to security for a man's person, reputation or goods is interfered with, neither knowledge nor specific intention need be proved This rule was known some time ago to apply to the exercise of rights of property, and such speculative doubt as remained was removed by the decision of the House of Lords in the leading case of *Allen* v *Flood* (1898, A C 1) We now know that it applies to the exercise of all common rights The exceptions are very few, and must be explained by exceptional reasons Indeed, only two are known to the present writer—malicious prosecution, and the misuse of a "privileged occasion" which would justify the communication of defamatory matter if made in good faith In each case the wrong lies in the deliberate perversion of a right or privilege allowed for the public good, though the precise extent of the analogy is not certain at present It was formerly supposed that an action by a party to a contract against a third person for procuring the other party to break his contract was within the same class, *i e*, that malice must be proved But since *Allen* v. *Flood*, and the later decision of the House of Lords in *Quinn* v *Leathem* (1901, A C 495), this view has ceased to be tenable The ground of action is the intentional violation of an existing legal right; which, however, since 1906, may be practised with impunity in Great Britain "in contemplation or furtherance of a trade dispute". Trade Disputes Act, sec 3 It must be remembered, however, that the presence or absence of personal ill will, and the behaviour of the parties generally, may have an important effect, when liability is proved or admitted in mitigating or aggravating the amount of damages awarded

We have already had to mention the existence of grounds of immunity for acts that would otherwise be wrongful Such grounds there must be if the law is to be enforced and justice administered at all, and if the business of life is to be carried on with any freedom Roughly speaking, we find in these cases one of the following conditions Either the defendant was executing a lawful authority; or he was justified by extraordinary necessity; or he was doing something permitted by legislation for reasons of superior utility, though it may produce damage to others, and either with or without special provisions for compensating damage; or he was exercising a common right in matters open to free use and competition, or the plaintiff had, by consent or otherwise, disabled himself from having any grievance

As Justice Holmes of the Supreme Court of the United States has said, we allow unlimited trade competition (so long as it is without fraud) though we know that many traders must suffer, and some may be ruined by it, because we hold that free competition is worth more to society than its costs A State with different economic foundations might have a different law on this, as on many other points This freedom extends not only to the exercise of one's calling, but to choosing with whom and under what conditions one will exercise it Also the law will not enquire with what motives a common right is exercised, and this applies to the ordinary rights of an owner in the use of his property as well as to the right of every man to carry on his business. The rule that a man's motives for exercising his common rights are not examinable involves the consequence that advising or procuring another, who is a free agent, to do an act of this kind can, *a fortiori*, not be an actionable wrong at the suit of a third person who is damnified by the act, and that whatever the adviser's motives may be. This appears to be included in the decision of the House of Lords in *Allen* v. *Flood*. That decision, though not binding in any American court, is approved and followed in most American jurisdictions. It is otherwise where a system of coercion

is exercised on a man's workmen or customers in order to injure him in his business The extension of immunity to such conduct would destroy the value of the common right which the law protects: *Quinn* v *Leathem*.

Individual Rights.—Owners and occupiers of immovable property are bound to respect one another's convenience within certain limits. The maxim or precept *Sic utere tuo ut alienum non laedas* does not mean that I must not use my land in any way which can possibly diminish the profit or amenity of my neighbour's. That would be false. It is a warning that both his rights and mine extend beyond being free from actual unlawful entry, and that if either of us takes too literally the more popular but even less accurate maxim, "Every man may do as he will with his own," he will find that there is such a head of the law as nuisance

From the point of view of the plaintiff, as regards the kind of damage suffered by him, actionable wrongs may be divided into four groups. We have some of a strictly personal kind; some which affect ownership and rights analogous to ownership; some which extend to the safety, convenience and profit of life generally—in short, to a man's estate in the widest sense, and some which may, according to circumstances, result in damage to person, property or estate, any or all of them. Personal wrongs touching a man's body or honour are assault, false imprisonment, seduction or "enticing away" of members of his family. Wrongs to property are trespass to land or goods, "conversion" of goods (*i.e*, wrongful assumption of dominion over them), disturbance of easements and other individual rights in property not amounting to exclusive possession. Trespass is essentially a wrong to possession, but with the aid of actions "on the case" the ground has been practically covered Then there are infringements of incorporeal rights which, though not the subject of trespass proper, are exclusive rights of enjoyment and have many incidents of ownership. Actions, in some cases expressly given by statute, lie for the piracy of copyright, patents and trade-marks. A wrong to a man's estate in the larger sense above noted is defamation—not a strictly personal wrong, because according to English common law the temporal damage, not the insult, is, rightly or wrongly, made the ground of action and the defendant's intention is immaterial It is even possible to write an actionable libel without knowing that one's words can be thought to reflect on the plaintiff, or (it seems) that there is any such person: so the House of Lords decided in *Hulton & Co* v *Jones* in 1910. Others are deceit, so-called "slander of title" and fraudulent trade competition, which are really varieties of deceit; malicious prosecution; and nuisance, which, though most important as affecting the enjoyment of property, is not considered in that relation only. Finally, we have the results of negligence and omission to perform special duties regarding the safety of one's neighbours or the public, which may affect person, property, or estate.

The law of wrongs is made to do a great deal of work which, in a system less dependent on historical conditions, we should expect to find done by the law of property We can claim or reclaim our movable goods only by complaining of a wrong done to our possession or our right to possess There is no direct assertion of ownership like the Roman *vindicatio* The law of negligence, with the refined discussions of the test and measure of liability which it has introduced, is wholly modern; and the same may be said of the present working law of nuisance, though the term is of respectable antiquity. Most recent of all is the rubric of "unfair competition," which is fast acquiring great importance.

It will be observed that the English law of torts answers approximately in its purpose and contents to the Roman law of obligations *ex delicto* and *quasi ex delicto*. When we have allowed for the peculiar treatment of rights of property in the common law, and remembered that, according to one plausible theory, the Roman law of possession itself is closely connected in its origin with the law of delicts, we shall find the correspondence at least as close as might be expected *a priori*. Nor is the correspondence to be explained by borrowing, for this branch of the common law seems to owe less to the classical Roman or mediaeval canon law than any other. Some few misunderstood Roman maxims have done considerable harm in detail, but the principles have been worked out in all but complete independence.

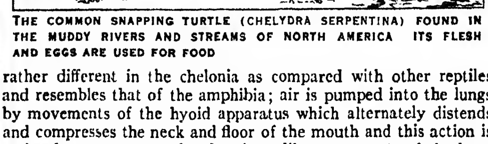
A list of modern books and monographs will be found at the end of the article on "Torts" by the present writer in the *Encyclopaedia of the Laws of England* (2nd ed.). Among recent editions of works on the law of torts and new publications the following may be mentioned here: Addison, by W. E Gordon and W H. Griffith (8th ed, 1906); Clerk and Lindsell, by Wyatt Paine (7th ed., 1921); J. W. Salmond, *The Law of Torts* (7th ed, 1928); Pollock (13th ed., 1929). In America: T. A Street, *The Foundations of Legal Liability* (1906) 3 vols. of which vol. i. is on Tort; F. M. Burdick, *The Law of Torts* (4th ed., 1926). (F. Po.)

TORTOISE, the name applied to some members of the order Chelonia, a group of Reptiles (*q v.*); the name is not consistently applied to any one section of the order but is generally used to designate a terrestrial animal, "turtle" being in Britain the equivalent name for a marine species (though in America it is more generally used), and "terrapin" or "water-tortoise" for a fresh-water chelonian They are toothless reptiles with well-developed limbs and a "shell" covering the body.

The "Shell."—This characteristic "shell" consists of an upper *carapace* and a lower *plastron*, the two being more or less firmly united at the sides by the so-called bridge Both carapace and plastron proper are bony structures built up from a number of elements which are firmly united by sutures, the carapace consists of a central row of from 10–12 plates most of which are fused to the vertebrae, a lateral row of 8 plates on each side fused to the ribs and about 23 small plates bordering its free edge; the plastron contains five paired elements and one unpaired. The union of the upper and lower halves of the shell may be rigid and bony or cartilaginous and flexible and in some forms transverse hinges are also developed In the majority of chelonians the bony shell is overlaid by horny plates, but these do not correspond with the underlying bones although their general arrangement is similar; they are of exactly the same nature as the horny scales which covers the head, limbs and exposed soft parts.

The shape of the "shell" varies in conformity with the habits of the animal; in strictly terrestrial forms it is usually high, domed, and sufficiently large to permit the head and limbs to be withdrawn into it, whereas in aquatic species, it is generally depressed and so much reduced in size that it offers little protection for the limbs Correlated also with the habitat is the shape of the limbs; in terrestrial species they are club-shaped, all the digits being bound together and only externally distinguishable by their claws whereas in the fresh-water dwellers the digits remain distinct and are connected by a web; the marine turtles have the fingers and toes all bound together and the number of claws reduced, but the whole limb is here transformed into a paddle.

Breathing.—As a result of the development of the shell and the consequent fixation of the ribs the method of breathing is



THE COMMON SNAPPING TURTLE (CHELYDRA SERPENTINA) FOUND IN THE MUDDY RIVERS AND STREAMS OF NORTH AMERICA ITS FLESH AND EGGS ARE USED FOR FOOD

rather different in the chelonia as compared with other reptiles and resembles that of the amphibia; air is pumped into the lungs by movements of the hyoid apparatus which alternately distends and compresses the neck and floor of the mouth and this action is assisted to some extent by the piston-like movements of the head and limbs in and out of the shell when the creature is active. Additional respiratory mechanisms have been developed by some aquatic species by means of which the oxygen dissolved in the water can be utilised

No recent chelonian possesses teeth, the jaws being covered

MARINE, FRESH-WATER AND TERRESTRIAL TORTOISES

1. Shark group in Fish hall of the American Museum of Natural History, showing a Loggerhead turtle swimming among sharks
2. Green turtle, caught by natives off the island of Tahiti. This marine species weighs as much as 1,000 lb. and furnishes the most edible turtle meat
3. The Cumberland terrapin, a fresh water species also seen on land
4. The South American Matamata, a marine turtle sometimes over a yard long, with a characteristic ridge of skin along its neck
5. Very young snapping turtles and unhatched eggs. The young turtles have the long tails and large heads characteristic of this type
6. Swimming soft shell turtle, a flat, almost circular form entirely covered with soft skin
7. Australian snake-necked turtle, a fresh water species with a long neck
8. Giant or elephant tortoise, a terrestrial species found on the Aldabra islands. Only a few giant tortoises are still in existence, some of which weigh over 600 pounds
9. Leatherback turtle, found off Block Island, R. I. The shell is leathery instead of being horny

with horny beak-like plates which usually have sharp cutting edges; terrestrial species are, as a rule, strictly herbivorous and though many aquatic species are impartial in their feeding habits the majority are carnivorous, many raptorial. The voice is not well developed, females as a rule only being able to hiss; males, however, in the breeding season at least utter cries which in smaller species may be only a feeble piping but in the Giant Tortoises are hoarse bellows Reproduction is always by means of eggs which are spherical and covered by a parchment-like or calcareous shell; they are buried in sand or loose earth

Species.—There are living at the present day some 225 species but these are probably only the surviving remnant of a formerly much more numerous group. They are cosmopolitan in their distribution except for the more recent islands and those northern and southern countries where the winter is too severe; in England their extermination seems to have been relatively recent

One recent chelonian differs from all the others in the structure of its shell, the elements which normally compose this structure being almost all absent and their function being assumed by a mosaic of small polygonal plates. On this account the animal has been placed in a separate group, the ATHECAE, to contrast with the others which are united as the THECOPHORA. This creature, the Luth or Leathery Turtle (*Sphargis coriacea*) is a marine, turtle-like animal inhabiting tropical seas and is the largest living chelonian; it reaches a length of 8 feet and may weigh nearly a ton, the back is devoid of horny plates and is covered by soft skin, the food consists of molluscs, crustaceans and fish and the eggs, like those of the other marine turtles, are laid on land; the female repairs to a sandy beach during the night, digs a shallow hole in which the eggs are deposited, covers them up, and returns to the sea; the chief breeding places appear to be the islands of the West Indies.

Thecophora.—These are subdivisible into 3 main groups, the *Trionychoidea* aquatic forms with a bony carapace and plastron but without horny plates, the *Cryptodira*, terrestrial and aquatic forms with a bony carapace and plastron covered with horny epidermal shields and retracting the neck by a vertical S-shaped bend and the *Pleurodira* resembling the *Cryptodira* but retracting the neck by a simple lateral flexure Of these groups the *Cryptodira* contains the largest number and the majority of the typical tortoises, its various families, based largely on characters of the bony shell, may be recognised by the following key based on external characters only.

I Digits more or less distinct with 4 or 5 claws; terrestrial or fresh-water.

A Pectoral shield (the 3rd paired shield of the plastron) separated from the marginal shields of the carapace by a series of small "infra-marginal" plates

(1) Tail long and crested; plastron small and cruciform American *Chelydridae*

(2) Tail long, covered with rings of scales; plastron large Asiatic *Platysternidae*

(3) Tail short North American *Kinosternidae* *Dermatemydidae.*

B Pectoral shields in contact with the marginals of the carapace *Testudinidae*

II Limbs paddle-shaped with one or two claws; marine. *Chelonidae*

Chelydridae.—Alligator Terrapins or Snapping Turtles Freshwater forms of north and central America, characterised by relatively huge heads, long alligator-like tails, rough shells and numerous soft projecting folds of skin on the neck and limbs. The two better known species, the Common Snapper (*Chelydra serpentina*) of the eastern United States and the Alligator Snapper (*Macrochelys temminckii*) of the Mississippi and Missouri basins, are both large, powerful creatures, and notorious for their vicious nature and the power of their jaws

Platysternidae.—A single species (*Platysternon megacephalum*) found in fresh waters in S China, Burma and Siam. The head is relatively very large and the neck long, a 14-inch specimen only measuring 5 inches along the carapace.

Kinosternidae.—These are the Musk Turtles of North and Central America, so called from the rather offensive odour of the secretion of their inguinal glands; they are small, aquatic creatures, rarely exceeding a total length of one foot and in many the front and hind lobes of the plastron are hinged and can be drawn up to the carapace when the head and legs are withdrawn into the shell *Sternotherus odoratus* the Stink Pot Terrapin of eastern North America is the best known species.

Dermatemydidae—Small Central American terrapins closely allied to and resembling the members of the preceding family

Testudinidae.—This family, containing the majority of tortoises is world wide in its distribution except the Australian region and its members show all gradations between thoroughly aquatic and exclusively terrestrial species The Batagur (*Batagur baska*) of Bengal, Burma and the Malayan region is exclusively aquatic, it attains a length (carapace only) of nearly 2 feet, is rather flattened and has the digits fully webbed. *Chrysemys* of eastern N America is also exclusively aquatic and the species of this and allied genera are extensively eaten, they are sold as "Slider Terrapins" to distinguish them from the Diamond Back Terrapins (*Malaclemys*) beloved by epicures

Clemmys, with species in S. Europe and N. Africa (*C leprosa*), Asia and N America (e.g, *C insculpta* the Wood Terrapin), is less aquatic than the preceding and the digital webs are correspondingly reduced Still less aquatic are the species of *Emys*, *E orbicularis* of Central Europe and Western Asia and *E blandingi* of southern Canada and the north-eastern United States, which have indications of a transverse hinge across the plastron This plastral hinge reaches a high degree of development in the North American Box Turtles (*Terrapene*) which can withdraw completely into their shell and close both openings; in structure these animals are water-tortoises, but they are terrestrial in habits and have the high, domed shell of the exclusively terrestrial genera such as *Kinixys*, *Pyxis* and *Testudo*. *Testudo* is an assemblage of herbivorous, terrestrial forms and contains, among others, the well-known Giant Tortoises, some of which reach a shell length of over 4 feet and may weigh over 600 lb There were three groups of these animals, one confined to the islands of the Galapagos Group where every small island had its own race and the largest several, another to the Mascarene Islands (Bourbon, Mauritius Rodriguez) and the third to the Seychelles-Aldabra Group Before the advent of man these creatures abounded in almost incredible numbers, but it was soon discovered that, on account of their ability to live for months without food, they formed an excellent supply of easily transported fresh meat for sailing vessels and their numbers were rapidly decimated

Somewhat approaching the Giant Tortoises in size are the African *T calcarata* and the South American *T. tabulata* but the remaining species of the genus are relatively small, *T elegans*, the Indian Star Tortoise, is black with yellow streaks radiating from the centre of each shield and the South African *T geometrica* has a similar pattern; in Europe there are 2 species, *T hermanni* of S Europe and Asia Minor and *T. marginata* of Greece the species commonly imported into England being *T graeca* of northern Africa and Asia Minor The N American Gopher Tortoises (*T polyphemus*) are burrowing creatures inhabiting dry, sandy country and constructing their own burrows, but the East African *T. tornieri* is cryptozoic in rocky country and hides in crevices

Chelonidae.—The true Turtles; the three common species are the Hawksbill (*Eretmochelys imbricata*) the Green (*Chelonia mydas*) and the Loggerhead (*Caretta caretta*). Of these, the first mentioned may be distinguished by its smaller size, the overlapping horny plates of the back and the hooked beak: it occurs in all tropical seas and is the source of the "tortoise-shell" of commerce. The horny shields of the carapace are stripped off by heat and when heated in oil or by steam they can be welded together to form slabs thick enough for manufacturing purposes The Green Turtle is the species used so much in the manufacture of turtle soup; it is a larger species than the Hawksbill attaining a length of close on 4 feet and the horny plates of the back do not overlap but meet edge to edge. All these turtles have the same general habits and distribution; the Green Turtle only is partially or entirely herbivorous, feeding on *Zostera* the marine grass, the

others preferring fish or molluscs. All lay their eggs in pits dug by the females on sandy beaches which are visited at night and it is then that large numbers are captured; the eggs, too, are edible so that in some regions the turtles are becoming scarce.

Pleurodira.

I. Shell covered with horny shields; limbs not paddle-shaped

A Neck completely retractile into the shell. *Pelomedusidae.*

B. Neck long, not hidden by the shell when retracted *Chelydidae*

II. Shell covered with soft skin, limbs paddle-shaped *Carettochelydidae*

Pelomedusidae, fresh-water dwellers in Africa and South America, *Pelusios* of Tropical Africa and Madagascar has the front lobe of the plastron hinged but *Pelomedusa* of the same regions lacks this character. *Podocnemis* similar to *Pelomedusa* inhabits the rivers of tropical S. America and reaches a considerable size

Chelydidae, the "Snake-Necked Turtles" of the fresh-waters of S. America, Australia and Papua They are all long-necked creatures with the typical depressed shells of aquatic tortoises, the many species are superficially very similar, the S. American Matamata (*Chelys fimbriata*) alone showing any peculiarities

Carettochelydidae, the single, rare Papuan species of this family, *Carettochelys insculpta,* superficially resembles the marine turtles in its paddle-shaped limbs, but the absence of horny plates is distinctive and suggests affinities with the next group

Trionychoidea.—This contains but a single family, the *Trionychidae.* In this family the bony carapace and plastron are much reduced in size and the whole creature is very flat, almost circular in bodily outline and entirely covered with soft skin; the digits are broadly webbed, only the three inner having claws, the jaws are hidden by fleshy lips and the snout is prolonged into a short, soft proboscis. All the members of the group are dwellers in the mud of slow-running rivers, lakes and ponds and are carnivorous; some species show what appears to be dimorphism connected with their diet, some individuals which appear to be fish-eaters having sharp-edged jaws and others having broad, crushing surfaces which suggest a diet of molluscs The six genera of the family are distributed throughout Africa, Asia and North America and are superficially very similar *Trionyx,* the most widely distributed genus, has species in regions inhabited by the family.

(H W. P.)

TORTOISESHELL. The tortoiseshell of commerce consists of the epidermic plates covering the bony carapace of the hawksbill turtle, *Chelonia imbricata,* the smallest of the sea turtles The plates of the back or carapace, technically called the head, are 13 in number, five occupying the centre, flanked by four on each side These overlap each other to the extent of one-third of their whole size, and hence they attain a large size, reaching in the largest to 8in. x 13in, and weighing as much as 9 ounces The carapace has also 24 marginal pieces, called hoofs or claws, forming a serrated edge round it; but these, with the plates of the plastron, or belly, are of inferior value The plates of tortoiseshell consist of horny matter, but they are harder, more brittle and less fibrous than ordinary horn Their value depends on the rich mottled colours they display—a warm translucent yellow, dashed and spotted with rich brown tints—and on the high polish they take and retain The finest tortoiseshell is obtained from the Eastern Archipelago, particularly from the east coast of Celebes to New Guinea; large supplies come from the West Indian islands and Brazil.

Tortoiseshell is worked precisely as horn; but, owing to the high value of the material, care is taken to prevent any waste in its working. The plates, as separated by heat from the bony skeleton, are keeled, curved and irregular in form They are first flattened by heat and pressure, and superficial inequalities are rasped away. Being harder and more brittle than horn, tortoiseshell requires careful treatment in moulding it into any form, and as high heat tends to darken and obscure the material it is treated at as low a heat as practicable. For many purposes it is necessary to increase the thickness or to add to the superficial size of tortoiseshell, and this is readily done by careful cleaning and rasping of the surfaces to be united, softening the plates in boiling water or sometimes by dry heat, and then pressing them tightly together by means of heated pincers or a vice. The heat softens and liquefies a superficial film of the horny material, and that with the pressure effects a perfect union of the surfaces brought together. Heat and pressure are also employed to mould the substance.

Tortoiseshell has been a prized ornamental material from very early times. It was one of the highly esteemed treasures of the Far East brought to ancient Rome by way of Egypt, and it was eagerly sought by wealthy Romans as a veneer for their rich furniture In modern times it is most characteristically used in the elaborate inlaying of cabinetwork known as buhl furniture, and in combination with silver for toilet articles. It is also employed as a veneer for small boxes and frames It is cut into combs, moulded into snuff-boxes and other small boxes, formed into knife-handles, and worked up into many other similar minor articles. The plates from certain other tortoises, known commercially as turtle-shell, possess a certain industrial value, but they are either opaque or soft and leathery, and cannot be mistaken for tortoiseshell A close imitation of tortoiseshell can be made by staining translucent horn or by varieties of celluloid

TORTONA (anc. *Dertona*), a town and episcopal see of Piedmont, Italy, in the province of Alessandria, from which it is 14 m E by rail, on the right bank of the Scrivia, at the northern foot of the Apennines, 394 ft above sea-level Pop (1921), 12,-494 (town), 20,076 (commune) Tortona is on the main line from Milan to Genoa; from it a main line runs to Alessandria, which branches to Novi and Castelnuovo Scrivia, and a steam tramway to Sale. Its fortifications were destroyed by the French after Marengo (1800); which was fought not far off, as were the battles of Novi (1799) and Montebello (1800–1859) The cathedral contains a remarkably fine Roman sarcophagus

Dertona is spoken of by Strabo as one of the most important towns of Liguria It stood at the point of divergence of the Via Postumia (*see* LIGURIA) and the Via Aemilia, while a branch road ran hence to Pollentia The local museum contains Roman antiquities found here In the middle ages Tortona was zealously attached to the Guelphs, on which account it was twice laid waste by Frederick Barbarossa, in 1155 and 1163 In 1176 it made a treaty with Barbarossa and the people of Pavia, and was taken back into favour by Henry VI. in 1193 It was the base headquarters of the British force in Italy in 1917–19

See F Gabotto, *Per la Storia di Tortona* (Biblioteca della Societa Storica Subalpina, fasc 96, 1922).

TORTOSA, a fortified city of Spain, in the province of Tarragona; 40 m by rail W S W of Tarragona, on the Ebro 22 m above its mouth Pop. (1920), 33,044 Tortosa, the *Dertosa* of Strabo and the *Colonia Julia Augusta Dertosa* of numerous coins was a city of the Ilercaones in Hispania Tarraconensis Under the Moors it was of importance as the key of the Ebro valley It was taken by Louis the Pious in 811, but was soon recaptured Having become a haunt of pirates, it was made the object of a crusade proclaimed by Pope Eugenius III in 1148, and was captured by Ramon Berenguer IV, count of Barcelona, assisted by Templars, Pisans and Genoese An attempt to recapture the city in 1149 was defeated by the women folk, who thenceforth received many privileges Tortosa fell to the duke of Orleans in 1708; during the Peninsular war it surrendered in 1811 to the French under Suchet, who held it till 1814 Tortosa is a walled town with crooked and ill-paved streets, and lofty, granite-built houses. There is a modern suburb on the opposite side of the Ebro. The cathedral occupies the site of a Moorish mosque built in 914. The present structure (1347), has its Gothic character disguised by a classical façade with Ionic pillars There are manufactures of paper, hats, leather, ropes, porcelain, majolica, soap, spirits and ornaments made of palm leaves and grasses. The river fisheries are important. Corn, wine, oil, wool, silk, fruits and liquorice (a specialty of the district) are exported The city is connected with Barcelona and Valencia by the coast railway, and with Saragossa by the Ebro valley line; it is also the terminus of a railway to San Carlos de la Rápita.

TORTURE, the general name for innumerable modes of inflicting pain, and especially for those employed as an incident of judicial process. From this point of view torture was always inflicted either as a means of eliciting evidence from a witness or from an accused person either before or after condemnation; or as a part of the punishment. The second was the earlier use.

Its development in mediaeval times may be traced to the decline of the ordeals and trial by battle While the appeal to God (which is so marked a feature of the ordeals) exists, confession is unnecessary. Thus, the capitularies of Charlemagne make no provision for torture, while including the earlier modes of procedure. When the fourth Lateran Council, in 1215, prohibited the clergy from participating in the ordeal, English law developed trial by jury for crime, and thus rendered the extraction of a confession of guilt from the prisoner unnecessary Continental law, on the other hand, considered a confession the best of all evidence, and all the machinery of the law was organized to obtain it.

Even when torture was a normal incident of judicial procedure, enlightened lay opinion was overwhelmingly opposed to its employment. Cicero (*Pro Sulla*), Seneca and St. Augustine condemn it, although the latter regards it as a necessity, while Ulpian, in Justinian's *Digest,* declares: "Torture (*quaestio*) is not to be regarded as wholly deserving or wholly undeserving of confidence; indeed, it is untrustworthy, perilous and deceptive For most men, by patience or the severity of the torture, come so to despise torture that the truth cannot be elicited from them; others are so impatient that they will lie in any direction rather than suffer torture, so it happens that they depose to contradictions and accuse not only themselves but others" Among later writers, Montaigne, Montesquieu, Bayle, Voltaire, Sonnenfels, Beccaria, Verri and Manzoni all condemn it The influence of Beccaria in rendering the use of torture obsolete was undoubtedly greater than that of any other legal reformer. He emphasizes the unfair incidence of torture, as minds and bodies differ in strength. Moreover it is to confound all relations to expect that a man should be both accuser and accused, and that pain should be the test of truth, as though truth resided in the muscles and fibres of a wretch under torture. Apologists of torture may be found chiefly among jurists, but authors of books of practice, and notably Damhouder, von Rosbach, von Boden and Voet, are aware of its deficiencies. Muyart de Vouglans derives torture from the law of God Other apologists are Simancas, bishop of Badajoz, Engel, Pedro de Castro, and in England Sir R. Wiseman.

Greece.—Both Aristotle and Demosthenes regard torture as the surest means of obtaining evidence. At Athens slaves, and probably at times resident aliens, were tortured, but free citizens only rarely, the practice being forbidden by a psephism passed in the archonship of Scamandrius Torture was sometimes inflicted in open court, and the rack was employed, even for free citizens. A list of tortures is given in the *Ranae* of Aristophanes (V 617) and the wheel is alluded to in *Lysistrata* (V. 846) Isocrates and Lysias refer to torture under the generic name of στρέβλωσις but it was generally called βάσανοι in the plural (*cf.* Lat. *tormenta*). Torture was frequently inflicted by Greek despots, and both Zeno and Anaxarchus are said to have been put to it.

Rome.—The Roman system was the basis of all subsequent European systems which recognized torture as a part of their procedure, and the rules attained a refinement beyond anything approached at Athens Cicero declares that the law of torture rested originally on custom, and no existing fragment of the Twelve Tables alludes to it. It is mentioned frequently by writers both of the republic and the empire. During the republic, a master had power to torture his slaves In the early empire, however, restrictions were imposed. A *lex Petronia* forbade masters to punish slaves by making them fight wild beasts, without magisterial authorization, while Antoninus Pius required a master who ill-treated his slave to sell him. Not until the later empire was the killing of a slave by excessive punishment made homicide. The law of the later empire, relating to torture, is set forth at length chiefly in the titles *De quaestionibus* of the *Digest* and the *Code*—the former consisting largely of opinions from the *Sententiae receptae* of Paulus, the latter being largely a repetition of constitutions contained in the Theodosian Code. Both substantive law and procedure were dealt with, but a large discretion was left to the judges. Torture was used both in civil and criminal trials, but in the former only upon slaves and freedmen or infamous persons (after *Nov* xc 1 i upon *ignoti* and *obscuri* if they showed signs of corruption)—*e.g*, gladiators—and in the absence of *alia manifesta indicia,* as in cases affecting inheritance. Only slaves were tortured during the republic, but in the empire it was extended to freemen accused of crime. Certain persons were exempt by a constitution of Diocletian and Maximian from the liability to torture, *e g*, soldiers, nobles of high rank, and their descendants to the third generation—*decuriones*—and their children under 14, and pregnant women. These exemptions did not extend to accusations of treason or sorcery. A freeman could be tortured only where he had been inconsistent in his depositions, or where there was a suspicion of lying. There were detailed rules concerning the torture of slaves, and the Romans believed that this was the most efficacious means of obtaining the truth. Unlike freemen, they could be tortured as witnesses, always on behalf of their master, against him only in treason, adultery, frauds on the revenue, coining and similar offences, attempts by a husband or wife on the life of the other, and in cases where a master had bought a slave in order that he should not give evidence against him The exemption from accusation by a slave extended to the owner's father, mother, wife or tutor, and a former master; but a slave-owning corporation was not privileged. Where a charge of adultery was brought against the wife, her husband's, her own and her father's slaves could be tortured. Detailed rules governed the application of torture Other modes of proof must first be exhausted, and the evidence (*argumentum* and *indicium*) must have advanced so far that the slave's confession alone was required to complete it The amount was at the discretion of the judge, but it must not injure life or limb, otherwise the judge became *infamis* Except in treason, the unsupported testimony of a single witness was not a sufficient ground for torture. Leading questions could not be asked The *quaesitor* asked the questions, the *tortores* applied the instruments The principal forms of torture were the *equuleus,* or rack, the *plumbatae,* or leaden balls, the *ungulae* or barbed hooks, the *lamina,* or hot plate, the *mala mansio* (comparable with the "Little Ease" of the Tower of London) and the *fidiculae,* or cord compressing the arm. As a part of punishment, torture existed in Rome from earliest times, when it was permitted in respect of defaulting debtors Later, crucifixion, mutilation, exposure to wild beasts in the arena, and other modes were in common use. Through the *leges barbarorum,* Roman doctrines relating to torture were transferred, with modifications, to mediaeval Europe.

The Church.—The Church, although adopting a good deal of Roman law, was at first definitely opposed to torture. Thus the synod at Rome in 384 condemned it. In 1282, a bull of Innocent IV. directed the civil power to torture heretics, but the canon law had little to say upon the subject, holding that although it was no sin in the faithful to inflict torture, a priest might not do so with his own hands In later times, torture was inflicted by the Inquisition. Torquemada's code of instructions (1484) provided that an accused might be tortured if *semiplena probatio* existed against him, *i.e*, so much evidence as to raise a grave presumption of guilt Confessions extracted during torture required subsequent confirmation, but retractation involved further torture or extraordinary punishment. One or two inquisitors, or a commissioner of the Holy Office, were bound to be present at all examinations. Following certain abuses, a decree of Philip II. in 1588 forbade torture without an order from the council, but the decree was not fully observed. An edict of the Inquisitor-General Valdès, in 1561, left torture to the prudence and equity of the judges. They must consider motives and circumstances before decreeing torture, and must declare if it were to be employed *in caput proprium, i.e.,* to extort a confession, or *in caput alienum, i.e.,* to incriminate an accomplice. Torture was not to be decreed until the termination of the process and after defence heard, and the decree was subject to appeal, but only in doubtful cases, to the Council of the Supreme. It was also only in doubtful cases

that the inquisitors were bound to consult the council. On ratification 24 hours afterwards of a confession made under torture, the accused might be reconciled, if sincerely repentant, or if convicted of bad faith he might be delivered to the secular power to be burned Torture had ceased to be inflicted before the suppression of the Inquisition, and a papal bull in 1816 decreed its abolition. The actual rules, *e g*, Torquemada's, were not so cruel as the construction put upon them by inquisitors. Thus Torquemada's direction that torture should only be renewed for retractation was evaded by terming renewed torture a continuation. Besides the two sets of rules already mentioned, those of Nicholas Eymenico, grand inquisitor of Aragon about 1368, and of Simancas, two centuries later, deserve mention In 1545 and 1550, Charles V. issued instructions for the guidance of inquisitors Abuses, however, were exceedingly frequent

England.—The English common law never recognized the legality of torture (except perhaps in the early ordeals) and Coke, commenting on Magna Carta, cap 29, observes. "No man destroyed, etc. that is, forejudged of life or limb, disinherited, or put to torture or death" (2 *Inst* 48 b) The Bill of Rights also provided that cruel and unusual punishments ought not to be inflicted. Judicial opinion was always in theory opposed to it, and in Felton's case (1628) a resolution of the judges declared "that he ought not by the law to be tortured by the rack, for no such punishment is known or allowed by our law" Accordingly, in only two instances was a warrant to torture issued by a common law judge, although it was an incident in criminal procedure for several centuries, being ordered either by the Crown or council, or some extraordinary tribunal, and especially by the star chamber Cases occur as early as the 13th century, and continue down to 1640 One case only is recorded after this date, three Portuguese being tortured at Plymouth during the Commonwealth The rack was introduced in the reign of Henry VI by the duke of Exeter, and was hence known as "the duke of Exeter's daughter" Other varieties of torture were "the scavenger's daughter," or manacles, which pressed the victim's head to his feet, the iron gauntlets or bilboes, and the cell called "Little Ease" In Elizabeth's reign, the rack was in constant use Witnesses were never tortured

One peculiar form of torture was not unknown to the common law—the *peine forte et dure.* If a prisoner refused to plead, remaining mute of malice, he was stretched upon his back, and pressed with heavy weights, until he either consented to plead, or died This practice was abolished by 12 Geo III c. 20, a case having occurred so late as 1726 Tying the thumbs with whipcord was frequently used instead of the *peine* Witch trials also involved incidents of torture, such as throwing the accused into a pond to discover whether she would sink or swim

As a part of punishment, torture by mutilation appears in pre-conquest codes and in the assize of Northampton (1176). Later examples are burning to death for heresy, drawing and quartering for treason, branding in the hand for felony, the pillory, the stocks, branks and ducking stool All these have now been abolished, although corporal punishment for robbery with violence and for juvenile offenders still exists

Scotland.—Torture was long a recognized part of Scottish criminal procedure. Numerous instances occur in the *Register of the Privy Council* The last warrant was issued in 1690, and it was finally abolished in 1708 Among the most celebrated forms employed in Scotland was the "boot." The "boot," comprising a long iron boot in which the foot was inserted, wedges being then driven between the limb and the boot, was not peculiar to Scotland for records are found in French criminal trials, and again in Ireland, where in 1583, Hurley, a priest, was tortured in Dublin by "toasting his feet against the fire with hot boots"; this species of torture was employed, not only for crime, but as an incident in religious persecution (Lecky, *Rationalism in Europe*, 1865, II., p. 45), and sometimes by the nobility for their own ends. Thus in 1605, a suit was brought against the earl of Orkney, for putting a son of Sir Patrick Bellenden in the boots. Other Scottish methods of torture were the rack, the pilniewinkis (known in England as the thumbikins, and resembling the thumbscrew), the caschie-laws (an instrument drawing the body and limbs together, heat being applied in some cases), the lang irnis (heavy weights, sometimes exceeding 50 stones), the harrow-bore (perforations through which the teeth of harrows were inserted), the pynebankis (a variety of the rack) and the artificial prevention of sleep.

Ireland.—Torture was recognized in Ireland neither by statute nor by common law, and few cases are recorded of its infliction. In 1566, however, the president and council of Munster, or any three of them, were empowered to inflict torture "upon vehement presumption of any great offence in any party committed against the queen's majesty"

British Colonies and Dependencies.—In any British possession, the infliction of torture has usually been regarded as contrary to law. In 1806, however, Sir Thomas Picton, the governor of Trinidad, was tried for subjecting Luisa Calderon to the torture of the piquet, in which the sufferer was supported only on the great toe, which rested on a sharp stake, and by a rope attached to one arm One of the grounds for defence was that torture was authorized by the Spanish law of the island The accused was convicted, but sentence was respited Warren Hastings was also charged with extortion from the begums of Oude by means of the torture of their servants. The Indian penal code now expressly forbids torture In Ceylon it was formerly allowed by the Dutch, but was abolished by royal proclamation in 1799.

United States.—In 1692, Giles Cory of Salem, accused of witchcraft, refused to plead, and was subjected to the *peine forte et dure* The American constitution forbids cruel and unusual punishments, on which there have been numerous decisions

CONTINENTAL EUROPEAN STATES

These fall into four main groups, the Latin, Teutonic, Scandinavian and Slav states The principles of Roman law were generally adopted in the first and second groups.

France.—In France, torture does not seem to have existed as a recognized practice before the 13th century. From then until the 17th century it was regulated by a series of royal *ordonnances,* and was applied only in the royal courts, its place in the seigneurial courts being supplied by the judicial combat The earliest *ordonnance* was that of Louis IX in 1254, for the reformation of the law of Languedoc It enacted that persons of good fame, though poor, were not to be put to the question on the evidence of one witness. In 1670, an *ordonnance* of Louis XIV regulated the infliction of torture for more than a century Two kinds were recognized, the *question préparatoire* and the *question préalable* The first was abolished by royal decree in 1780, but in 1788 the parlements refused to register a decree abolishing the *préalable* Torture of all kinds was abolished by an *ordonnance* of Oct 9, 1789, however, and the modern *code pénal* enacts that criminals employing torture to further their ends shall be guilty of assassination, whilst it is also an offence to torture a person under arrest.

Italy.—The law as it existed in Italy is contained in a long line of authorities chiefly supplied by the school of Bologna, beginning with the *glossatores* and continued by the *post-glossatores* until the system attained its perfection in the vast work of Farinaccius in the early 17th century, where every possible question that could arise is treated with revolting completeness. The writings of the jurists were supplemented by a large body of legislative enactments in most of the Italian states, extending from the constitutions of the Emperor Frederick II. down to the 18th century.

Farinaccius was procurator-general to Pope Paul V., and the principal feature of his work is the minute and skilful analysis of *indicia, fama, praesumptio,* and other technical terms. For every infliction of torture a distinct *indicium* is required. A single witness or an accomplice constitutes an *indicium* This rule does not apply where torture is inflicted for discovering accomplices or a crime other than that for which it was originally inflicted. Torture may be ordered in all criminal cases, except small offences, and in certain civil cases, such as denial of a *depositum,* bankruptcy, usury, treasure trove and fiscal cases. It may be inflicted on all persons, unless specially exempted (*e g.,* clergy and minors) and even those exempted may be tortured by command of the sovereign. There are three kinds of torture, *levis, gravis* and *gra-*

vissima, the first and second corresponding to the ordinary torture of French writers, the last to the extraordinary. This last was as much as could possibly be borne without destroying life. The judge could not begin with torture; it was only a *subsidum.* If inflicted without due course of law, it was void as a proof.

Among other important writers was Julius Clarus of Alessandria, a member of the council of Philip II Generally, he follows Farinaccius. He puts the questions for the consideration of the judge with great clearness These are—whether (1) a crime has been committed, (2) the charge is one in which torture is admissible, (3) the fact can be proved otherwise, (4) the crime was secret or open, (5) the object of the torture is to elicit confession of crime or discovery of accomplices The clergy can be tortured only in charges of treason, poisoning and violation of tombs.

Other Italian writers of less eminence are Guido de Suzara, Paris de Puteo, Aegidius Bossius of Milan, Casonus of Venice, Decianus, Follerius and Tranquillus Ambrosianus Torture was abolished in Tuscany in 1786, largely owing to the influence of Beccaria, and other States followed The *puntale*, or piquet, however, existed in practice at Naples until 1859 Savonarola, Machiavelli, Giordano Bruno, Campenella are among those subjected to torture in Italian history Galileo appears only to have been threatened with the *esame rigoroso* The historical case of the greatest literary interest is that of the persons accused of bringing the plague into Milan in 1630 by smearing the walls of houses with poison

Spain.—In Spain, Roman law was carried through the Visigothic code and the *Fuero juzgo* down to the *Siete partidas*, compiled by Alfonzo the Wise in 1243, and promulgated in 1256. Torment is defined as a manner of punishment which lovers of justice use, to scrutinize by it the truth of crimes committed secretly, and not provable in any other manner Repetition was allowed in case of grave crimes There were the usual provisions for the infliction of torture only by a judge having jurisdiction, and for the liability of the judge for exceeding legal limits Subsequent codes did little more than amend the *Partidas* in matters of procedure In Aragon, while it was an independent state, torture was not in use to the same extent as in other parts of Spain. It was abolished in the 13th century by the General Privilege of 1283, except for vagabonds charged with coining A statute of 1335 made it unlawful to put any freeman to the torture. On the other hand, the Aragonese nobility had power to put a criminal to death by cold, hunger and thirst The jurists dealing with the subject are not as numerous as in Italy, no doubt because Italian opinions were received as law in all countries whose systems were based on Roman law Among them are Suarez de Paz, Antonio Gomez and Alvarez de Velasco The Peruvian Juan de Hevia Bolanos, who wrote at the beginning of the 19th century, should also be noted The principal Spanish tortures, according to Suarez de Paz, were the water and cord, the pulley or *strappado*, the hot brick, and the *tablillas*, or thumbscrew and boot combined.

Teutonic States.—Germany (including Austria) possesses the most extensive literature and legislation on the subject The principal writers are Langer, von Rosbach, von Boden, Ulrich Tengler, Remus, Casonus and Carpzow Legislation was partly for the empire, partly for its component states Imperial legislation dealt with the matter in the Golden Bull (1356), the Ordinance of Bamberg (1507) the Carolina (1532) and the *Constitutio criminalis theresiana* (1768) Torture was formally abolished in the empire in 1776. In Prussia it was practically abolished by Frederick the Great in 1740, formally in 1805 Even before its abolition it was in use only to discover accomplices after conviction. In some other states it existed longer, in Baden as late as 1831.

The Netherlands.—The principal legislative enactment was the code of Philip II, known as the *Ordonnance sur le style* (1570). One of its main objects was to assimilate the varieties of local custom, as the *Nueva recopilacion* had done in Spain three years earlier. Certain cities of Brabant, however, still claimed the privilege of torturing in certain cases not permitted by the ordinance, *e.g*, where there was only one witness This law continued to be the basis of criminal procedure in the Austrian Netherlands until 1787, and in the United Provinces until 1798 The principal text-writers are Damhouder, van Leeuwen and Voet, who took the same view as St Augustine as to the uselessness of torture, and compared its effect with that of trial by battle.

Scandinavian Countries.—There is a notice of torture in the Icelandic code known as the Grágás (about 1119). Judicial torture is said to have been introduced into Denmark by Valdemar I. in 1157 In the code of Christian V. (1683) it was limited to cases of treason It was abolished by the influence of Struensee in 1771, but nothwithstanding this he was threatened with it, though it was not actually inflicted, before his execution in 1772. In Sweden torture never existed as a system, and in the code of 1734 it was expressly forbidden It was however occasionally inflicted, as in England, by extrajudicial authorities, called secret committees. The "cave of roses," where reptiles were kept for the purpose of torture, was closed by Gustavus III in 1772

Slav Countries.—The earliest mention of torture is that of the mutilation provided for certain offences by the code of Stephen Dushan in 1349 In Russia torture does not occur in the recensions of the earlier law It was possibly of Tatar origin, and the earliest mention of it in an official document is probably in the Sudebnik of Ivan the Terrible (1497) In the ordinance of 1556 there are elaborate regulations, which were not always observed in periods of political disturbance, and torture was used even as a means of enforcing payment of debts The reaction begins with Peter the Great and culminates with Catherine II, who was largely influenced by the opinions of Beccaria and Voltaire In the instructions to the commission for framing a criminal code (1776) it is declared that all punishments by which the body is maimed ought to be abolished, and that the rack violates the rules of equity and does not produce the end proposed by the laws It was formally abolished by Alexander I in 1801, and in 1832 the *Svod Zakonov* subjected to penalties any judge who presumed to order it. But even as late as 1847 it was inflicted in one or two exceptional cases

ASIATIC COUNTRIES

Numerous accounts of tortures inflicted by Asiatic monarchs survive in the narratives of early travellers Of these, Olearius' *Voyages and Travels of the Ambassadors*, translated by John Davies (1662) is informative From these accounts it is apparent that torture was used regularly in the East both as an incident in judicial process, and as a part of punishment, and in some countries at least there seem to have been few checks on its employment beyond the whim of the monarch In Persia, Olearius records that such punishments as mutilation and sawing asunder were in use In India, again, the local despots employed torture as a mode of extracting evidence

Japan.—Japanese law was particularly severe, both procedurally and in its punishments In trials for theft, a piece of red-hot iron was placed in the hands of the accused, who then flung it away If his hand was unburned, he was innocent, if burned guilty The punishment for theft involved tying the offender to great canes in the form of a cross, and his body was then twice run through diagonally by a spear Confession was usually necessary before conviction, and in order to extract it, a "boot" consisting of heavy wooden planks was employed, and also the bow-strings As a punishment, crucifixion was in general use, and accounts of fiendish tortures inflicted on Christians in the 17th century survive (*See* Olearius 154–5, and Murdoch's *History of Japan*)

China.—In China, and other countries where the Chinese criminal code was accepted with local modifications (*e g*, Annam and Burma) some regulation of the use of torture was attempted, although abuses were frequent. As in Japan, confession by the accused was necessary before punishment. The *Ta T'sing Lu Li*, the code of the Manchu dynasty, therefore, prescribes certain forms of judicial torture. These were applicable to witnesses also, and include the "boot" (which appeared in two forms: [1] boards between which the leg of the accused was crushed, and [2] a receptacle in which the leg was placed and boiling oil poured), the finger-compressor, kneeling on chains and beating the face Those below 15 years of age, or over 70, were exempt

from torture, and also those suffering from permanent disease or other infirmity. Other forms, more cruel than those sanctioned by the code existed, although, according to the code, a magistrate who applied torture wantonly or arbitrarily was liable to prosecution Among the illegal tortures reported by the *Chinese Repository* (vol IV.) to be in use at the beginning of the 19th century were nailing to boards, beds of iron, red-hot spikes, boiling water, knives for cutting the tendon Achilles, the beauty's bar (so named after the wife of a judge, and comprising three cross bars to which the breast, the small of the back, and the legs bent up were fastened), the parrot's beam (in which the prisoner was raised from the ground by strings round the fingers and thumbs, attached to a beam) and the refining furnace. Torture was also an incident in many punishments, execution by slow cutting to pieces being the most famous In addition there were flogging (both with heavy and light bamboo) and the cangue, an instrument resembling, and having the same object as the pillory. Though theoretically abolished at the beginning of the 20th century, torture is still practised in many parts of China

TORY: *see* WHIG AND TORY

TOSARI, the chief mountain resort in Java, Dutch East Indies It is situated about 25 m from Pasuruan, from which it is reached by a good motor road, with easy gradients, through delightful country, by way of Gondang, Pasrepan and Poespa Tosari is built on a long, winding tree-clad ridge, a spur of the Tengger mountains, at an average altitude of 5,840 ft. above sea-level, with a very steep descent facing north-eastwards to the Straits of Madura It has a marvellous view over the mountains, and is a centre for many excursions

Tosari has a very modern and well equipped sanatorium, situated amidst beautiful gardens and grounds, several hotels, shops and a native (Tenggerese) village, with a temperature which ranges from a mean of 68 6° in August to 62 2° in January, and an absolute maximum of 71·2° and an absolute minimum of 49·5°. The nights are generally cold and clear, and the climate, with abundant sunshine, is very invigorating

TOSCANELLA: *see* TUSCANIA.

TOSTIG (d. 1066), earl of Northumbria, was a son of Earl Godwine, and in 1051 married Judith, sister or daughter of Baldwin V, count of Flanders In the year of his marriage he shared the short exile of his father, returning with him to England in 1052, and became earl of Northumbria after the death of Earl Siward in 1055 He was intimate with his brother-in-law, Edward the Confessor, and in 1061 he visited Pope Nicholas II at Rome in the company of Aldred, archbishop of York. Tostig introduced a certain amount of order into the wild northern district under his rule; but his severity made him exceedingly unpopular, and in 1065 Northumbria broke into open revolt. Declaring Tostig an outlaw and choosing Morkere in his stead, the rebels marched southwards and were met at Oxford by Earl Harold, who, rather against the will of the king, granted their demands. Tostig sailed to Flanders and thence to Normandy, where he offered his services to Duke William, who was related to his wife and who was preparing for his invasion of England. He then harried the Isle of Wight and the Kentish and Lincolnshire coasts, and, after a stay in Scotland and possibly a visit to Norway, joined Harald III. Hardrada, king of Norway, in the Tyne Together they sailed up the Humber and at Gate Fulford, near York, defeated Earls Morkere and Edwine and entered York. But Harold, now king, was hurrying to the north. Taking the Norwegians by surprise at Stamford Bridge he destroyed their army on Sept. 25, 1066, and in this battle both Tostig and the king of Norway were slain. Tostig's two sons took refuge in Norway, and his widow Judith married Welf, duke of Bavaria.

TOTALIZATOR. Betting on horse races, without the aid of bookmakers as intermediaries, is conducted by two methods, known as the totalizator (or tote) and the pari mutuel systems. In principle they are alike. Money staked by backers is pooled, and, when the result of a race is known, shared by those who have backed the winner. But whereas all bets made through a totalizator are at once automatically massed in a single pool, those made through a pari mutuel are in the first instance formed into a series of separate pools, only, however, finally to be amalgamated. The totalizator, when efficiently equipped and worked, is the more expeditious instrument, but it is also the more costly to install. The totalizator building and machinery at Randwick racecourse, Sydney, cost about £80,000 An outfit of a similar character at Longchamp, Paris, used for the first time in March, 1928, entailed an even bigger outlay; but, whereas the Randwick machine deals with only one pool, that at Longchamp provides for two separate pools—one for straight-out, or win, bets, and the other for place bets. Owing to the high cost of installing a totalizator capable of handling a large number of bets it has been the general practice to fit it with machinery for dealing with one pool only The major portion of such pools, say 60 or 75%, is divided among the backers of the winner and the remainder among backers of the second and third horses. In Australia and New Zealand, where the tote originated, this method of distributing the pool has been accepted as fair and satisfactory. In other parts of the world it has not been approved. In the United Kingdom, in France and other continental countries, and in the Americas, speculators demand the opportunity of backing a horse to win only; if they also wish to back it to secure a place that must be another transaction. Hence the widespread popularity of the pari mutuel system which, at a comparatively low cost, gives facilities for both win and place betting, with independent pools.

The Pari Mutuel.—The pari mutuel method was invented about 1872 by a Frenchman named Oller. His apparatus was extremely simple It consisted of blocks of consecutively-numbered tickets or vouchers (the tickets in each block bearing the racecard number of one of the horses running) and a wooden shed, open in front, to accommodate the men selling the tickets or paying out over winners For many years this system was privately conducted in opposition to bookmakers, but eventually it was adopted by the controllers of racing in France, who realized the possibility of obtaining revenue by appropriating a small percentage of the turnover. Then the French Government came in, imposed regulations, banished bookmakers, and, while allowing the turf authorities to work the pari mutuel, received a percentage of the turnover in return for the concession The money handed over to the Government was, and has continued to be, devoted to the furtherance of horse breeding, the provision of drinking water in rural districts, and to other beneficent objects Eleven per cent of the turnover is, in France, deducted before the pools are distributed among the holders of winning tickets. Four-elevenths of this rake-off is retained by the turf authorities who, after meeting the cost of working the pari mutuel, disburse the balance by increasing racecourse amenities for the benefit of the public, paying premiums to breeders of winning horses, enhancing the value of racing stakes, and generally improving the equipment and tone of the French turf. In 1927 the pari mutuel turnover at the racecourses near Paris, together with those at Deauville and Caen, amounted to 1,425,256,462 francs

Origin of the Totalizator.—The application of mechanism to the mutuel system of betting dates from 1880. That year a man in New Zealand named Ekberg, who had studied Oller's procedure, conceived the idea of automatically recording bets. He devised a machine for the purpose, called it a totalizator, and used it for the first time at the Canterbury Jockey Club's meeting at Christchurch, N.Z., in 1880. Before many years had elapsed the tote, which had undergone considerable improvement, drove bookmakers off the New Zealand racecourses, obtained a footing in Australia, India and other eastern countries, and now has reached Europe. The efficiency of the modern electrically-worked totalizator excites admiration and wonderment.

Pari Mutuel in America.—In America the development of Oller's primitive pari mutuel followed more closely the original idea. Instead of there being one large machine for recording bets there are several small ones. The registration of the bets is effected by means of hand levers, operated by a man known as the clicker. While betting on the race is in progress each machine is worked as a separate unit, but when the race is started and betting ceases the totals recorded at each machine are passed on to a central office where the grand aggregates are ascertained. This process may be a trifle slower than that of the modern tote, but the trained calculators are, nevertheless, able to declare the dividends payable with astonishing celerity. The American and Canadian machines, costing little more than £100 ($500) each, mark a tremendous advance on the antiquated method by which the pari mutuel is still operated in France

It was not until 1908 that the pari mutuel system of betting was methodically exploited in the United States In the spring of that year it was adopted in Kentucky. The innovation proved very unpopular. Attendance at race meetings became so small that the executives had to reduce the stakes they offered. Two years later, however, a complete change had taken place. It was then declared that the pari mutuel was "doing more to fortify the sport, safeguard and re-establish it, than all other agencies and influences combined" Subsequently the pari mutuel was adopted in Canada and Maryland, and eventually it came to be used on practically all American racecourses except those in the State of New York, where anti-betting laws are still in force, to be circumvented only by what is called "oral" betting with the aid of bookmakers The amazing progress racing has made in the United States of late years is largely the result of the pari mutuel and the 5 or 6% levy on turnover permitted by the laws of the several States concerned In return for this concession the racecourses pay the State exchequer a daily licence fee of from £1,000 to £1,500 ($5,000 to $7,500). This arrangement also obtains in Canada, where a Government inquiry held after the World War resulted in a report that the pari mutuel form of betting was the one calculated to benefit racing most and do the least harm to the community at large.

From time to time spasmodic efforts have been made to establish the pari mutuel in Great Britain The crudest of methods were employed, and then only by venturesome individuals ignorant of the impediments placed in their way by the Betting Houses Act of 1853, one clause of which prohibits anything in the nature of a "place" at which betting is conducted, and makes it illegal for persons to "resort" to such places. It was obviously impossible to conduct a tote or install pari mutuel apparatus without contravening that law. But in 1928, further experiments both at and away from the course were made in Great Britain, and in the Irish Free State the establishment of a tote or pari mutuel was legalized. (E. Mo.)

TOTANA, a town of eastern Spain, in the province of Murcia, on the Lorca-Murcia railway. Pop. (1920) 14,072. The town consists of two parts, the Barrio de Sevilla and Barrio de Triana. Water is conveyed to Totana from the Sierra de Espuña by an aqueduct 7 m. long. Saltpetre is obtained among the hills, and there is a thriving trade in wheat, oranges, olives, almonds, and wine from the Sangonera valley.

TOTEMISM. The term "totemism" is used for a feature of the religion and social organization of widespread occurrence amongst primitive peoples. The name *totem* is derived from an Ojibway word, but has now been generalized by anthropologists to describe an institution, the Ojibway form of which is not typical. Unfortunately, many writers have used the term totemism very loosely for any beliefs and practices dependent upon some supposed connection between animals and persons. The term should be restricted to those cases where a systematic association of groups of persons with species of animals (occasionally plants or inanimate objects) is connected with a certain element of social organization. In the widest use of the term, we may speak of totemism if: (1) the tribe said to be totemic consists of a number of groups (totem groups) comprising the whole tribe, each of which groups has a certain relationship to a species (totem), animate or inanimate; (2) the relation between each group and species is of the same general kind for each group; and (3) a member of one of these totemic groups cannot (except under special circumstances) change his membership.

By this definition one essential peculiarity of totemism is the association of groups of persons with groups of animals or objects, not of individual persons with individual animals, a cômmon enough phenomenon, which, however, it is desirable not to include under totemism Another peculiarity is the division of the tribe into several totemic groups, so that, while every member of the tribe has a totem, persons living in the same locality may yet differ as to their totems As to the determination of the membership of the totem-group, *i e*, the social side of totemism and the nature of the relationship between totem-group and totem, *i e*, the religious side of totemism, one kind of totem-group is commoner than any other, viz, the clan, an exogamous group (*i e*, a group within which marriage is forbidden), determined by descent, either through the father (patrilineal descent), or through the mother (matrilineal descent)

The clan (*q v*), is a group of great importance in primitive society, for it determines behaviour in a variety of ways, and is often of more importance than smaller groups, such as the family, or wider groups, such as the tribe. Members of a clan generally regard themselves as closely related, whether or not they can trace relationship genealogically, and frequently hold themselves and are held by others to be mutually responsible for the actions of their clan-brothers In some parts of the world, where clans are widely dispersed, the totem serves as the only sign of clan-relationship, and a man will be welcomed, on account of his totem, as a clan-brother by distant members of his clan, whom he has never seen, and will also avoid sexual relations with the women of that group, though unable to trace relationship The discovery of this association of totemism with the clan has given rise to one of the most interesting problems of anthropology, for it would seem that any theory of origin of totemism must also explain exogamy Although totemism is generally associated with the clan, the tribe is also sometimes divided into totemic groups, which are not exogamous For example, the Arunta (*q.v.*), of central Australia are divided into totemic groups, membership of which depends upon the accident of position of the mother at the moment of realization of pregnancy, and there is no exogamic restriction on the members of these groups. There are also totemic groups in Africa and elsewhere that are more or less endogamous (*i e*, required to marry within the group) Furthermore, a tribe may be divided in more than one way into totemic groups; for example, in Australia we sometimes find, in addition to totemic clans, moieties (exogamous halves of the tribe, each of which includes a number of clans), and marriage-classes (groups with indirect descent, which are specially connected with the regulation of marriage), which may be more or less totemic, and even a division of totems according to sex.

Variations of the relationship between totem-group and totem, are considerable in different parts of the world In the first place, the totem shows extraordinary variety. While an animal-species is the most usual form of totem, plant-species are by no means uncommon, and classes of material objects are occasionally found· even abstract qualities, such as "pride," the totem of a clan of a weaver caste in Madras, and "red," the totem of an Omaha clan A peculiar variety of totem is the split totem, in which only part of a thing is the totem: *e g*., instead of buffaloes, buffalo tongues

occur as the totem of one Omaha sub-clan. No doubt, split totems are the result of division of a totemic group into several groups. Cross-totems, however, are less intelligible A cross-totem consists of one part of more than one kind of thing; *e g*, the ends of things are the cross-totem of a certain Samoan group, the ears of animals of any species the totem of a Mahili clan, Bengal. Again, one totemic group may have a number of totems, which are then called linked totems; *e g*, clans in south-east New Guinea are always associated with a species of bird, of plant, of fish and of snake, the last three being subordinate to the bird totem.

Although there are considerable differences in the relation between totem-group and totem, owing to differences in the kind of totem, there are also great differences between tribes, apart from this In one tribe we may find a strong avoidance of the totem-animal, which may neither be killed nor eaten, while in other tribes the same animal may be killed with comparative impunity. Nevertheless, this tabu on killing or eating the totem seems to be typical of totemism, and some avoidances in connection with the totem are probably present in all cases But although these tabus may be of great severity—an offender may be severely punished by his totem-group, and, if not punished by his own totem-group, may yet be supposed to suffer through the action of the totem itself—they apply only to the particular totem-group For example, an Australian, whose totem is the witchetty-grub, will respect and avoid this animal, but will not hinder his friends and relations of other clans from making use of this food, and will even conduct ceremonies of which the avowed object is the increase of the totem, so as to provide food for other clans in the tribe In some cases, the totemic tabus must be observed by persons outside the totem-group; *e g*, in south-east New Guinea, where a man is a member of the totem-group of his mother, the totems of the father are even more rigidly tabu than his own totems, and amongst the totemic peoples of Africa, it is common for a woman to adopt the totem-avoidances of her husband Curiously enough, associated with severe tabus on the killing of the totem a totemic sacrifice has been reported from Australia, in which the totem-animal is cruelly killed and eaten

The totemic tabu is usually associated with a belief in some sort of kinship between the totemic group and the totem, which makes the tabu more intelligible In line with this is the frequent belief in descent from the totem, or of totem and totem-group from some common ancestor Another expression of this attitude towards the totem is the performance of ceremonies, in which the totem is represented symbolically or realistically Badges, masks and mutilations may also be used to make this identification Finally, although worship of the totem or prayer never occurs—animal worship has little in common with totemism—it is not unusual for the totemic group to believe that members of the totem species assist the group by means of omens, or in other ways Such being the general characteristics of totemism in all those cases which it is convenient to regard as totemism, a survey of the chief areas of totemism will reveal the diversity of form which totemism takes

Australia.—Totemism has generally been regarded as occurring in Australia in its most complete and original form, not so much on account of the elaborateness of Australian totemism, but because totemism has been regarded as the most primitive religion, and Australians are the most primitive people that we know Both these propositions can be disputed, but Australian totemism is of exceptional interest, for the greater part of Australian religion may be brought under the heading "totemism." Australian totemism has an equally important economic and social side. Among the tribes of central Australia all those important happenings, such as the origin of man and his customs, and the recurrence of death and birth, are well explained in totemic terms, for in olden (*alcheringa*) days there were only totemic beings, emu, grub, and so on, half animal in form, half human. These spirits were creative and made the stock of souls, which have ever since been the souls of human beings by continual reincarnation, these souls themselves being totemic in nature Birth is thus due to the entry of one of these spirits into the womb of a woman, death to its departure from the body. Between incarnations these spirits abide in certain centres, known as totem-centres, and tend to be associated with certain objects, which are kept in these centres, and which are used in totemic ceremonies. It might seem that such a theory of birth and death would offer difficulties, except in such cases as the Arunta, where the totem of the child is not determined by descent, but the native gets over the difficulty by supposing that these localized spirits, when their time for reincarnation arrives, wander from the totem-centre until they find a woman of the right totem, or a woman whose husband is of the right totem, according as descent is matrilineal or patrilineal In the ceremonies of initiation into manhood, also, totemic ideas are dominant. Initiates become conversant with various sacred objects, such as those connected with the soul, and symbolic objects, constructed for particular ceremonies symbolizing in one way or another the totems of the group. Elaborate decorations of the person, dramatic representations of the activities of the totemic ancestors in *alcheringa times*, continuing often for days, and other symbolic activities, all with more or less of a totemic motive, take place on these occasions. At certain times of the year, most Australian tribes conduct elaborate rites the object of which is to increase the totem species These appear to be mainly of the nature of sympathetic magic

Melanesia and Polynesia.—In this region we find every degree of totemism, from an institution containing the main features mentioned above, to complete absence of all these features. For example, in the Santa Cruz islands we find exogamous clans, each possessing one or more totems, usually animals; the totem may not be killed or eaten, and there is usually a definite belief in descent from the totem In the extreme west of Papua (where there are two moieties) and in south-east New Guinea and parts of the Solomons we find totemism of similar form, yet in other parts of the Solomons and in the New Hebrides and Banks islands totemism is absent, though there are customs which suggest survivals of an earlier totemism; in fact, the Banks islanders, while lacking totemic clans, have certain beliefs very similar to those of the Arunta of central Australia, but unsystematic A number of men and women strictly avoid killing certain species of animals or plants on account of a supposed kinship with them This belief is based on the belief that the mother owed her pregnancy in some way to the entry into her womb of an animal of the species avoided This belief appears to be maintained alongside some understanding of the true nature of the process of procreation In Polynesia we find a religious system, which in places, such as Samoa, appears to have developed out of totemism, for many totemic characters are discernible

India.—As a social system, if little more, totemism appears in parts of India For instance, the Santals of Bengal are divided into a number of patrilineal clans, exogamous and totemic, and each of these into a number of sub-clans, also exogamous and totemic There is avoidance of the totem, in some form or another, by the clan or sub-clan Totemism also occurs in Assam, in Central India and Madras, with traces elsewhere

Africa.—Except for the region of the great lakes, totemism is sporadic in Africa. The Baganda of Uganda may be cited as an example of well-developed totemism. The Baganda are divided into some 40 patrilineal exogamous clans Each of these has a principal and a secondary totem, usually an animal or plant, neither of which is killed or eaten by the clan. There are other avoidances, more or less connected with the totem; for example, members of the leopard clan may not eat meat which has been torn or even scratched by an animal We do not find traditions of descent from the totem amongst the Baganda, and the belief in descent from the totem is uncommon elsewhere in Africa. A nominalistic explanation of the origin of the Baganda totems is given; for example, the lion clan of the Baganda, with the eagle as secondary totem, explain their totems as follows: Kimtu, a royal ancestor of the clan, killed a lion and an eagle, and had their skins made into royal rugs, since when the beast and the bird have been regarded as sacred. There is one curious anomaly in Baganda totemism. While a man normally takes his totem

from his father, there is an exception in the case of royalty, a man taking the totem of his mother in addition, and rarely maintaining the royal totem.

North America.—Throughout the greater part of North America we find totemism in a more or less typical form, and the frequent grouping of totemic clans into moieties reminds one of the Australian variety. Other features of American totemism, however, mark it oft clearly from the Australian variety. While the tie between members of the totemic group may be as strong as anywhere else in the world, the attitude towards the totem is usually quite different, and the theory of totemic souls is wanting Often, in America, the totem is little more than a clan-badge, and the totem is often killed by the totemic clan. Nevertheless, elaborate and picturesque legends of the origin of totemic clans from the totem by some sort of descent are common enough. Totemism is not particularly associated with the less developed tribes of North America—rather the reverse; and we find both matrilineal and patrilineal descent of the totemic clans Amongst the strongly matrilineal Iroquois of the east we find a straightforward division of the various tribes into a small number of exogamous clans, of which the totems are animal species, the clans usually being grouped into two moieties Although a few traditions of direct matrilineal descent from an animal of the totemic species have been recorded, the clans usually deny relationship with their totems, and show no regard whatever for them Passing westward, some of the Siouan tribes provide examples of a more complex totemic system For example, the Ponkas are divided into moieties, the moieties into phratries, the phratries into clans, and the clans into sub-clans, each of these classes being more or less totemic and exogamous Here definite tabus are connected with the totems of the clans In the west, particularly the north-west coast, totemism is not clearly distinguishable from another socio-religious institution, peculiar to North America, the cult of guardian spirits The guardian spirit is acquired individually, sometimes quite late in life, by a process usually of fasting and religious exercise, which causes the guardian spirit to appear to the candidate in a dream or vision. Since the guardian spirit usually has an animal form, it is sometimes called an individual totem—clearly a misnomer. Sometimes the guardian spirits capable of acquirement by members of the tribe are divided out between the clans, or other social groups of the tribe, and sometimes the guardian spirit is not clearly individual in nature, but is rather of the nature of a species of animal. In so far as this is the case we have an approximation to totemism A complication of this sort is found in the totemism of the north-west coast peoples, who make the so-called totem-poles The student will find a mass of data on totemism arranged geographically in Sir J G. Frazer's work *Totemism and Exogamy* (1910)

Prominence was given to the association of totemism with exogamy, found throughout the world with few exceptions Where totemism is not associated with exogamy it is not difficult to suppose that exogamy has been lost With considerably less confidence it may be supposed that tribes, containing exogamous groups, have lost their totemism. Finally there are some peoples, *e g.*, the Andaman islanders, and the Eskimo, at a primitive level of culture, who have neither exogamous groups nor totemism. From this distribution of totemism and exogamy it follows that any theory of totemism must either be a "psychological" theory, explaining both totemism and exogamy, or a "historical" theory, which regards totemism, wherever it occurs, as the result of a spread of cultural influence from some one centre where the totemic complex originated. By a "psychological" explanation is meant an explanation in terms of observed facts about the behaviour of groups, or by means of generalizations about the behaviour of groups deduced from known psychological principles. If, antecedently to the development of a given institution, it could be stated on psychological grounds that an institution of that sort would probably develop, then such an institution can be said to be explained psychologically Early theories of totemism have not explained in this sense, for totemism and exogamy have only been shown to be probable, independently of the development of the one or the other, from which it follows that the distribution of totemism and exogamy, assumed above, would not occur, *e.g.*, if, owing to the nature of man and his attainment of some very simple form of society, it were probable that he should develop totemic ideas and practices, and also that he should develop exogamous groups, but for reasons other than those which lead to his developing totemism, then it would be indeed surprising that most peoples who have the one institution have the other, while those who, although in a primitive state of society, do not have the one do not have the other The difficulty can be got over by supposing that totemism and exogamy are necessarily developed by man in the course of his evolution, but it is difficult in this case to offer a plausible explanation of the disappearance of totemism and exogamy among some very primitive peoples, and its retention by others at a more advanced stage of civilization

Two theorists may be mentioned for their attempts to provide a psychological explanation of both totemism and exogamy; viz, Durkheim and Freud For Durkheim the totem results from the action of the group on the individual. The group is the nearest and most powerful coercive force to which the individual is subject, particularly when the group is in violent activity and the individual is conscious of this overpowering influence, when he loses himself completely in the group Symbolic expression alone can be given to such a force; hence the totem is a sacred symbol, symbolizing that very real force, the clan Hence totemic symbols are sacred rather than the totem-species itself (and this, it must be admitted, is true, at least for Australia).

But why, it may be asked, should there be many clans and totems, and not one totemic group? Here Durkheim becomes obscure If there are already several groups, then only in so far as the effective unity of each group is felt should there be more than one totemic group within the tribe. Passing over this difficulty, we have still to enquire why the totemic group is exogamous: the answer is not very convincing It would take too long to follow the various steps which give unity and intelligibility to the scheme, but it is the tabu on the blood of the clan which is ultimately responsible for exogamy

Freud's attempt to give a single explanation of totemism and exogamy is comparatively recent, and he appears to have indicated the direction in which we are to seek an explanation, whatever the adequacy of his presentation.

Prior to the development of culture, man is supposed to have lived in "cyclopean" families, containing a principal male who monopolized the women, including his own daughters, and prevented his sons from having intercourse within the family. What more natural than that the sons should combine and kill the father? But the attitude of the sons is ambivalent, combining both affection and hostility The murder committed, the sons deny themselves the fruits of the deed, owing to the operation of a psychological process familiar to psycho-analysts, and the group becomes exogamous. The affective ambivalence towards the father has also provided the beginnings of totemism. By substituting an animal for the father, a process of symbolism which psycho-analysts consider fundamental in human nature, the animal becomes a vehicle for that affective attitude towards the father which is for the moment repressed With the killing of the father by the momentary release of this repressed *Oedipus complex*, both totemism and exogamy are born The group with one father, and therefore one totem, is exogamous, and the totem becomes the object of observances, which are really the expression of the *Oedipus complex*, which has now become more completely repressed by means of a social mechanism. The difficulties in the way of this theory are considerable, and have been critically analysed by Profs Kroeber and Malinowski. Freud's theory has recently been elaborated and modified in a comprehensive study of Australian totemism on psycho-analytic lines by Dr. Géza Roheim. While the search for a "psychological" explanation of totemism does not reward us with any convincing theory of its origin, an "historical" explanation is equally elusive, though it has been maintained by one school that the distribution of totemism can only be explained on the assumption of diffusion from a single centre, a conclusion which, as we have already

seen, follows if no psychological explanation of totemism combined with exogamy can be found. No evidence for the existence of exogamy, and only the most slender evidence for totemism is provided in the Egyptian centre from which the totemic complex is supposed to have spread; in fact, on this theory totemic exogamy is derivative in the various parts of the world to which totemism spread from a kind of dual organization with marriage injunctions The only "historical" explanation of totemism which has been elaborated is, therefore, no more, if no less, convincing than the numerous "psychological" explanations which have been offered

Dissatisfied with this impasse that the search for explanations leads to, both in the case of totemism and in that of many other primitive institutions, many anthropologists have renounced the search for psychological or historical explanations, and confine themselves to the search for the functions of institutions Possibly this is the only kind of explanation of totemism within our grasp, and, although there is reason to suppose that totemism without function (occurring as a survival merely), occurs in some places, it must be admitted that, until totemism is understood in this functional sense in those cases where it appears to be a significant part of the culture of the group it is premature to attempt to account for its origin.

TOTILA (d 552), king of the Ostrogoths, was chosen king after the death of his uncle Ildibad in 541, his real name being, as is seen from the coinage issued by him, Baduila At the beginning of his reign, he collected together and inspired the Goths to win a victory over the troops of the emperor Justinian, near Faenza. Having gained another victory in 542, in the valley of Mugello, he left Tuscany for Naples, captured that city, and then received the submission of the provinces of Lucania, Apulia and Calabria Totila's conquest of Italy was marked not only by celerity but also by mercy Towards the end of 545 the Gothic king prepared to starve Rome into surrender, making at the same time elaborate preparations for checking the progress of Belisarius who was advancing to its relief The Imperial fleet only just failed to succour the city, which was plundered by Totila Its walls and other fortifications, however, were soon restored, and Totila again marching against it was defeated by Belisarius, who, however, did not follow up his advantage Several cities were taken by the Goths, while Belisarius remained inactive and then left Italy, and in 549 Totila advanced a third time against Rome, which he captured through the treachery of some of its defenders. His next exploit was the conquest of Sicily, after which he subdued Corsica and Sardinia and sent a fleet against the coasts of Greece. Justinian, thereupon entrusted the conduct of a new campaign to the eunuch Narses, Totila marched against him and was defeated and killed at the battle of Tagina in July 552.

TOTNES, GEORGE CAREW, or Carey, Earl of (1555–1629), English politician and writer, son of Dr George Carew, dean of Windsor, and Anne, daughter of Sir Nicholas Harvey, was born on May 29 1555, and was educated at Broadgates Hall, Oxford, where he took the degree of M A in 1588. After holding various military and diplomatic appointments he accompanied Essex in the expedition to Cadiz in 1596 and to the Azores in 1597. In 1598 he attended Sir Robert Cecil, the ambassador, to France. He was appointed treasurer at war to Essex in Ireland in March 1599, and on the latter's sudden departure in September of the same year, Carew became first a lord justice, and in 1600, president of Munster, where his vigorous measures enabled the new lord deputy, Lord Mountjoy, to suppress the rebellion. He returned to England in 1603 and was well received by James I., who gave him many honours. In 1610 he revisited Ireland to report on the state of the country; and in 1618 pleaded in vain for his friend Sir Walter Raleigh. He received his earldom in 1626. He died on March 27, 1629, leaving no issue. Besides his fame as president of Munster Carew had a considerable reputation as an antiquary.

Carew made large collections of materials relating to Irish history and pedigrees, which he left to his secretary, Sir Thomas Stafford, reputed on scanty evidence to be his natural son, while some portion has disappeared, 39 volumes after coming into Laud's possession are now at Lambeth, and 4 volumes in the Bodleian library A calendar of the former is included in the State Papers series edited by J. S Brewer and W. Bullen His correspondence from Munster with Sir Robert Cecil was edited in 1864 by Sir John Maclean, for the Camden Society, and his letters to Sir Thomas Roe (1615–17) in 1860 Other letters or papers are in the Record Office, among the mss at the British Museum and calendared in the *Hist MSS. Com Series*, *Marquess of Salisbury's MSS.*

TOTNES, a market town and municipal borough in the Totnes parliamentary division of Devon, England, on the Dart, 29 m S.S.W. of Exeter, by the G.W railway Pop. (1921) 3,983. It stands on the west bank of the river, and is joined by a bridge to the suburb of Bridgetown It was formerly a walled town, and two of the four gates remain Many old houses are also preserved, and in High street their overhanging upper stories, supported on pillars, form a covered way for foot-passengers The castle, founded by the Breton Juhel, lord of the manor after the Conquest, was already dismantled under Henry VIII; but its ivy-clad keep and upper walls remain The grounds form a public garden Close by are the remains of St Mary's priory, which comprise a large Perpendicular gatehouse, refectory, precinct wall, abbot's gate and still-house, also the Perpendicular church of St Mary. The guildhall is formed from part of the priory Vessels of 200 tons can lie at the wharves near the bridge The industries include brewing, flour milling, and the export of agricultural produce, chiefly corn and cider. Trout and salmon are plentiful in the river

Totnes (*Toteneis, Totton*) was a place of considerable importance in Saxon times; it possessed a mint in the reign of Aethelred, and was governed by a portreeve In the Domesday Survey it appears as a mesne borough under Juhel of Totnes. Its earliest charter dates from 1215.

TOTONICAPAN, the capital of the department of Totonicapan, Guatemala, on the same high plateau as Quezaltenango, from which it is 12 m E N E. Pop (1925) 30,888 Totonicapan is inhabited mainly by Quiché Indians, employed in the making of cloth, furniture, pottery and wooden musical instruments. There are hot mineral springs in the neighbourhood. In 1838 Totonicapan was declared an independent republic, in which the adjoining departments of Sololá and Quezaltenango were included. This State existed for two years, and was then again merged in the republic of Guatemala. The city suffered greatly in the earthquake of April 18, 1902

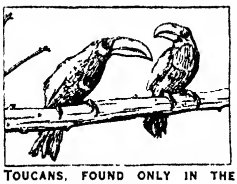
TOTTENHAM, an urban district of Middlesex, England, and suburb of London, 6½ m N of London Bridge, and adjoining Edmonton on the south. Pop. (1921) 146,711. Its full name, not now in use, was Tottenham High Cross, from the cross near the centre of the district. The present structure was erected *c.* 1600. Formerly Tottenham was noted for its "greens," in the centre of one of which stood the famous old elm trees called the "Seven Sisters"; these were removed in 1840, but the name is preserved in the Seven Sisters road. Bruce castle, on the site of the old mansion of the Bruces, but built probably by Sir William Compton in the beginning of the 16th century, was occupied by a boarding-school founded by Mr. (afterwards Sir) Rowland Hill in 1827 on the system he instituted at Hazlewood. Birmingham. It became public property in 1892; the grounds are now used as a public park. All Hallows church, Tottenham, was given by David, king of Scotland (*c.* 1126) to the canons of the church of Holy Trinity, London, and parts of the old building still remain.

In the reign of Edward the Confessor the manor of Tottenham was held by Earl Waltheof, and passed later, by marriage, to

the royal family of Scotland, and so to Robert Bruce and his co-heirs. The parliamentary borough of Tottenham returns two members to parliament.

William Bedwell, the Arabic scholar, was vicar of Tottenham, and published in 1632 a *Briefe Description of the Towne of Tottenham*, in which he printed for the first time the burlesque poem, the *Turnament of Tottenham*.

TOTTENVILLE, a former village of Richmond county, New York, U S.A , and since 1898 a part of New York city It is on the southern shore of Staten Island in New York bay and on Staten Island sound, about 20 m S.W of the south extremity of Manhattan Island The "Billopp House" here (still standing) was the scene of the conference, on Sept 11, 1776, between Lord Howe, representing Lord North, and Benjamin Franklin, John Adams and Edward Rutledge, representing the Continental Congress, with regard to Lord North's offer of conciliation This house, originally called the "Manor of Bentley," was built by Capt. Christopher Billopp (1638–1726), who sailed from England in an armed vessel, the "Bentley," in 1667, and, by circumnavigating Staten Island in 24 hours, made it, under the ruling of the duke of York, a part of New York From the duke of York he received 1,163 ac of land, including the present site of Tottenville The village was long known as Bentley, but in 1869 was incorporated (under a faulty charter, revised in 1894) as Tottenville, apparently in honour of Gilbert Totten, a soldier in the Revolution



TOUCANS, FOUND ONLY IN THE WESTERN HEMISPHERE

TOUCAN, the Brazilian name for a bird of the family *Ramphastidae*, characterized by their huge but light beaks

The type of the family is *Rhamphastes toco*, of Guiana and Brazil. The beak, 8in long and 3in high at the base, is deep orange with a large black spot near the tip The eye is surrounded by a bare orange space, the plumage is black except for the white throat, edged beneath with red The tail is nearly square In many allied species, the bill is parti-coloured *R vitellinus* inhabits Trinidad, but all the remaining members of the family are confined to the mainland, where they do not extend north of Mexico. In the Andes, they reach an elevation of 10,000ft.

TOUCH, SENSE OF. In the environment of every animal, the solid, impenetrable objects with which it may collide play an important part Sensitiveness to touch, comparable to our own, is, therefore, generally developed. The manner in which an animal reacts to contact stimuli depends, principally, on the force of the contact All such stimuli which exceed a certain degree act as repellants, and feeble, defenceless animals seek to escape from them This is evident already in the simplest animals, such as the amoeba. It is sufficient to touch one of the protruded pseudopodia of an amoeba with a pointed, glass needle to bring about its immediate retraction. Already in many infusorians there are extraordinarily developed tactile cilia; if another animal comes into contact with them, it causes the infusorian to swim hastily away (fig. 1)

FIG. 1.—DIOPHRYS HYSTRIX, AN INFUSORIAN WITH PARTICULARLY LONG TACTILE CILIA (AFTER VON BUDDENBROCK)

In multicellular animals the reaction to mechanical impulses differs very much, in accordance with the defensive powers of the individual. This is sufficiently well known in the higher animals. Defenceless animals, such as earthworms, or gasteropods, flee, or withdraw into their protective shells; on the other hand, those capable of defending themselves, such as the large Crustacea, cuttlefishes or sea-urchins meet the assault by active defensive movements. The example last mentioned is, perhaps, of sufficient interest for it to be discussed more particularly

If we touch a sea-urchin on any part of its surface, one of three things happens In the first case, all the spines which are situated in the neighbourhood of the part stimulated bend towards it. If some animal were the cause of the contact it would, thus, be grievously stung by the sharp spines, and put to flight. In the second case the pedicellariae come into action (fig 2) These are pincers consisting of three small snapping blades on a pliant stalk They turn towards the place whence the contact stimuli proceed, and wave their gaping jaws rapidly to and fro They bite firmly into the skin of the enemy, or into its hairs, and assist, either in putting it to flight, or in holding it fast and bringing it into contact with the tube-feet round the mouth, where it is consumed Lastly, in a third case, the whole sea-urchin moves in a direction calculated, if possible, to take it out of the sphere of the stimulus

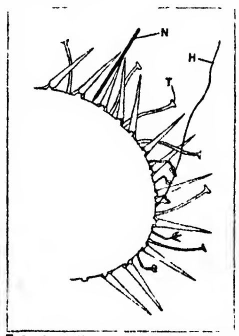


FIG 2—SURFACE OF SEA-URCHIN UNDER MECHANICAL STIMULATION BY NEEDLE N AND HAIR H. T IS A TUBE FOOT

The common crab, particularly the male, reacts to strong contact stimuli by assuming its very characteristic defensive attitude It turns towards its opponent and presents its widely-opened pincers If the enemy still continues to approach, it strikes at it with great force.

Some animals are able to assume an appearance of death when attacked The most pregnant examples of this are furnished by insects The death-feigning reflex usually consists in the animal drawing in its legs, and remaining perfectly motionless, continuing thus even if maltreated in the most violent manner In such a case, the assailant, a bird for example, thinks it is dealing with a dead thing instead of a food animal, and gives up the attack Insects such as these, which feign death, usually resemble very closely some inanimate object, such as a piece of wood or a twig The stick-insects provide the best known examples of this

As was mentioned at the beginning, the sense of touch often serves to prevent an animal dashing itself against hard objects when moving from place to place The whirligig beetle, *Gyrinus*, which we see skimming rapidly to and fro over the surface of the water in summer, bears eloquent witness to the degree of sensitiveness attained The careful observer will soon perceive that these lively little creatures never collide with any object which may be floating on the surface of the water; they also do not run against one another, although, often, many may be skimming about in a restricted space The sense organs which render this possible are situated in the feelers, as Eggers has proved. The antennary flagella are borne free in the air; their amputation does not cause alterations in the animal's conduct. On the other hand, the second basal joint rests on the water like a float (fig. 3). It contains numerous sensory cells, bearing stylets, which are

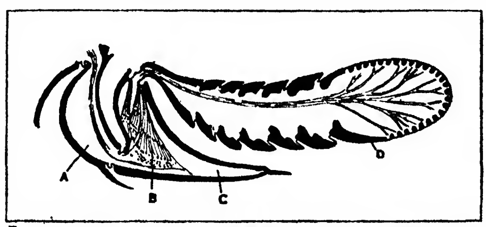

FIG 3.—ANTENNA OF WHIRLIGIG BEETLE. (A AND C) BASAL JOINTS OF ANTENNA, (B) JOHNSTON'S ORGAN, (D) ANTENNARY FLAGELLUM

grouped together in "Johnston's organ" With the assistance of these the animal perceives in some way the proximity of solid objects; it may, perhaps, react to the waves of water reflected to it by these objects.

Among vertebrates, bats are able to perform a, perhaps, even greater feat. As was known already to the naturalists of the 18th century, even blind bats are able to avoid all obstacles which may be placed in their path

An opposite condition to that discussed hitherto prevails in not a few cases in which the animal seeks to establish contact with a solid object, and is uneasy if it cannot do so This phenomenon has been given a special name, and is known as "thigmotropism." In most animals the soles of the feet are usually placed in constant contact with solid bodies The vigorous attempts at "righting" which are made by almost every animal if it falls upon its back, until it regains its feet once more, are due, in many cases, to the effort to bring the feet again into contact with solid bodies This may be seen particularly well in insects If we put a caterpillar upon its back it immediately rights itself If, however, we place between its feet a twig to which it can adhere, it remains peacefully upon its back, and even eats in this position. The following experiment is easily carried out, and shows this every clearly. A thread is gummed firmly on to the back of a fly, and is then attached to a stand, the feet of the insect being allowed to hang down free. If, now, a small ball of paper is placed between them, the fly begins at once to run about upon it.

The normal running movement, therefore, follows contact of the feet with the solid object. In leeches, contact stimuli are of particular importance in locomotion Uexkuell showed that in these animals a quite definite co-ordination exists between the action of the suckers and the contraction of the muscles of the body When the leech is adhering by means of its posterior sucker, it stretches out its body at full length, searching thus for a suitable surface on which to fasten its anterior sucker When the anterior sucker is attached, the posterior sucker relaxes its hold, and immediately a reflex contraction of the longitudinal muscles of the body takes place Both phases, taken together, give rise to the characteristic looping motion of the leech (*See* fig. 4) If, however, we throw the leech into water without giving

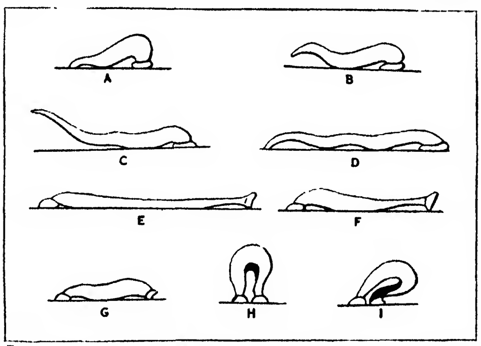

FIG. 4—CRAWLING MOVEMENT OF A LEECH. (A–D) POSTERIOR SUCKER IS ATTACHED, AND THE WORM EXTENDED; (E–G) ANTERIOR SUCKER IS ATTACHED, POSTERIOR IS FREE, ANIMAL IS CONTRACTED, (H–I) RE-ATTACHMENT OF THE POSTERIOR SUCKER

it an opportunity of attaching itself by one of its two suckers, swimming movements at once take place

Thigmotropism, however, appears also in quite another form. It was thought at first that many animals which are in the habit of dwelling in narrow tubes (such as many worms), or in crevices in wood, or under bark are led to seek out their hiding places through an aversion to light The truth of the matter is that such an animal feels comfortable only if its body is in contact, as much as possible, on all sides, with solid surfaces. Thigmotropic worms will also creep into glass tubes, and some insects hide between glass slides, in spite of being fully exposed to daylight when in these retreats. Under natural conditions, the thigmotropic animal thus avoids the covetous eyes of its enemies, since in nature there are no transparent solid objects.

Sensitiveness to mechanical stimuli has a very important use in the sense which in higher animals makes them aware of the relative position of the parts of the body. To the majority of human beings it certainly appears quite as a matter of course that they are able to take hold of their noses with their hands Science teaches, however, that this is possible only through stimulation of numerous sensory cells in the skin, which are pulled or pressed when the arm or the hand is moved If the skin is narcotized, the power of touching any particular part of the body is lost

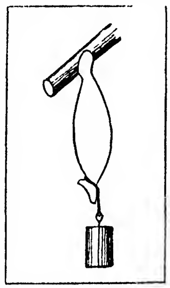

FIG 5—LEECH SUPPORTING WEIGHT (AFTER CAHNHEIM AND UERKÜLL)

It is of interest that some of the lower animals, particularly arthropods, possess a similar sense Insects and Crustacea show this in the very vigorous way in which they clean the limbs and the body, making use of legs specialized for this purpose The precision with which the decapod Crustacea, after moulting, place fresh statoliths in their statocysts is astonishing (*See* also HEARING) They seize grains of sand, or similar material in their delicate pincers, and are able to introduce them into the statocyst through its minute opening.

As regards the lower animals, we do not yet know anything for certain about the localization of the sensory cells which function in these movements In Crustacea, this faculty is distributed apparently among sensory hairs in the region of the joints, in insects we know that there are free nerve endings in the skin of the joints

To the mechanical sense belongs also the sense of "strength" When a man lifts a weight, he notices exactly if it is heavy or light, and, according to this sensation, he regulates the amount of energy to be expended The leech shows that a similar sense is present also in the lower animals. It has been mentioned already that this animal contracts when the anterior sucker is attached and the posterior sucker is free When the animal is in this position we can force it to lift fairly heavy weights, which, under certain circumstances, it will support for hours together (*See* fig 5) If we cautiously hold up the weight with one hand, the worm experiences a sensation of considerable relief, and alters the impulse it sends to its muscles This is clearly proved by the fact that, as soon as we withdraw our hand again, the worm is drawn out by the weight which it formerly had supported

Stimulation of the Nervous System by Mechanical Influences.—Every organism, in order to be able to move vigorously, requires constant stimulation from without. To man this statement does not appear very credible, but it can occasionally be proved quite clearly in the lower animals. In the article on HEARING, we have described the statocysts of the lower organisms, which usually act as balancing organs It has been generally proved by experience, that the animals fall into an enduring state of debility after these statocysts have been removed by an operation. They are no longer able to make powerful movements; we can express mathematically the amount of diminution in the gripping power of the chelae of a crustacean caused by the removal of the statocyst It is not yet determined for certain how this connection between the statocysts and the muscular strength is to be explained Apparently, the mechanical stimulation of the sensory cells of the statocyst by the statoliths affects the central nervous system of the animal, thus, as we may say, rousing it into activity in a somewhat similar manner to that in which coffee stimulates a tired man.

Flies furnish a particularly remarkable instance of this. In these insects, the posterior wings are transformed into oscillating clubs or "halteres," which, during flight, move simultaneously with the wings, with great rapidity (figs. 6a, 6b). If these

clubs are removed or stuck down firmly, the insect is no longer capable of flight. It can neither rise from the ground nor maintain itself in the air. It appears from this that the active movement of the halteres is essential. Formerly, it was thought that the halteres were a kind of balancing organs, and it was believed that the fly lost its power of balance after they had been removed. This, however, is excluded by the extremely minute size of the halteres. Now, however, numerous sensory cells affected by mechanical stimuli have been found on the basis of the halteres. These are so arranged that they must be vigorously stimulated by the movement of the halteres, which, apparently, has this stimulation as its object. We may assume that this affects the nervous system of the fly in a similar way as stimulation of the statocyst affects crustaceans. The fly is able to send the necessary impulses to the muscles of flight only if this constant stimulation is present.

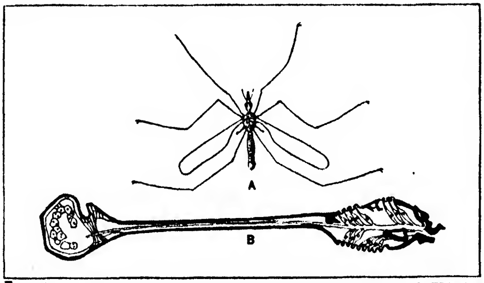

FIG. 6.—(A) TEPULA, A FLY (DADDY-LONG-LEGS) SHOWING HALTERES; (B) LONGITUDINAL SECTION THROUGH A HALTERE, SHOWING SENSE ORGAN AT THE BASE (AFTER PFLUGSTEDT)

Wille has recently discovered a similar, and, considered as a whole, certainly still very problematical contrivance in the Brazilian locust, *Rhipipterix chopardi*. This insect bears sense organs on the under side of its hind legs; if these are put out of action by being stuck down, the insect is prevented from springing and flying.

Structure of Tactile Organs.—There is not very much to be said on the subject of the anatomy of the sensory cells which serve for the transmission of mechanical stimuli. It has been mentioned already that, even among unicellular animals (infusoria) tactile cilia are occasionally to be found. (*See* fig. 1.) In multicellular animals there are frequently found, projecting from the surface of the body, groups of cells bearing small hairs like cilia, which are usually considered to be tactile organs (fig. 7 and 8). Several of these organs from the skin of different kinds of Echinoderms are shown in fig. 7. In fig. 8 is represented a "sensilla" from the skin of the leech. In yet other cases we find what are called free nerve-endings (fig. 9), the nerve cells, which are deeply situated beneath the skin, sending one or many fine processes up to the outer surface. Unfortunately, in no case can it be proved definitely that the groups of sensory cells mentioned really serve for the perception of mechanical stimuli. The only way in which this might be determined, namely by removing the organs by an operation and experimenting with the animals thus treated, is not practicable, owing to the large number of the organs, which usually are distributed over the whole surface of the skin. This difficulty of proof occurs also when dealing with arthropods, in which the tactile organs exhibit an astonishing diversity. The rule that the cuticle is particularly thin where the sensory cells are situated (*see* fig. 10) applies to all these creatures (insects, crustaceans, spiders). When a sensory cell is quite separated from the exterior by a layer of chitin, it is impossible that it can perceive chemical stimuli, and we may assume, with some degree of probability, that it is an organ for the perception of mechanical stimuli.

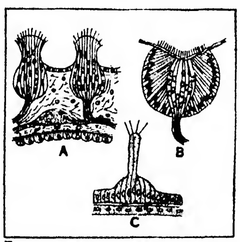

FIG. 7.—EPITHELIAL SENSE-ORGANS OF ECHINODERMS

(A) Ophuroid, transverse section through the wall of an ambulacral foot; (B) Sea-cucumber, epithelial sense-organ from a tentacle; (C) Sensory papilla from an ambulacral foot of a feather-star

Among Crustacea the most general form in which these occur is the sensory hair; in insects we find in addition sensory cones (fig. 10 B), sensory pits (10 C), cup-shaped sense organs (fig. 10 D), and so forth. In insects only there is found also a particular kind of sense organ, the chordotonal organs. In form they are like a cord stretched between two flat surfaces of the body wall, and, doubtless, function when these surfaces are displaced in any way. The following parts may be distinguished in them:—the sensory cell with the proximal enveloping cell, the distal enveloping cell (cap cell) which connects the peculiar stylet (scolopala) with the hypodermis, and, lastly, the ligament which spans the whole apparatus. Such organs are found singly or in groups on the body and extremities of insects. The organs which most resemble them are "Johnston's organs" in the feelers. (*See* fig. 4.)

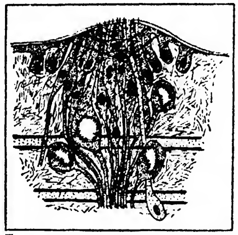

FIG. 8.—SENSILLA FROM THE SKIN OF A LEECH WITH OPTIC CELLS, AND APPARENTLY TACTILE CELLS (AFTER HACHLOFF)

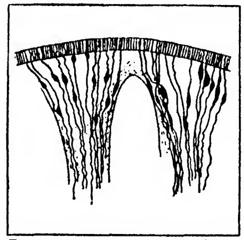

FIG. 9.—ANTERIOR END OF A SHORT HORN OF A SLUG (ARION), SHOWING FREE NERVE ENDINGS (AFTER RETZIUS)

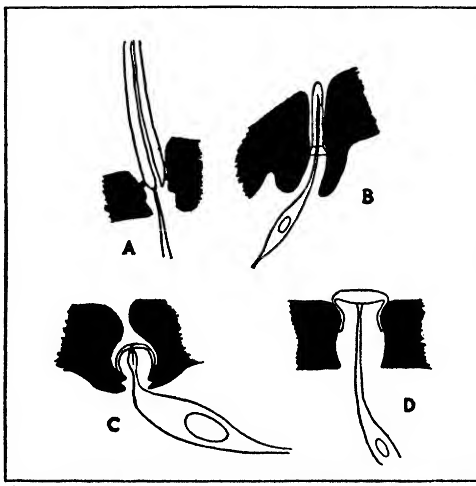

FIG. 10.—FOUR DIFFERENT KINDS OF TACTILE ORGANS FROM THE WATER-BEETLE (AFTER HOCHREUTHER)

In the auditory organs of insects the chordotonal organs certainly receive the sound waves; what purpose they serve in Johnston's organ, or in the simpler organs, is not yet known.

The Sense of Temperature.—Since heat, as is well known, consists in a mechanical vibration of molecules, the sense of tem-

perature, also, must be included in the mechanical sense It goes without saying that the higher animals possess a sense of temperature which is very similar to that of human beings. It is of greater interest to prove its presence in the lower animals. The simplest method of deciding whether an animal reacts to heat stimuli is by the use of the temperature organ. This consists of a narrow box, about a meter in length, the bottom of which is

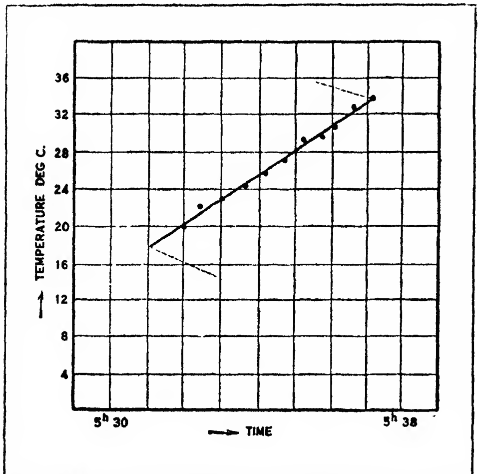

FIG 11.—RISING OF THE TEMPERATURE OF THE BODY OF A MOTH DURING VIBRATORY MOVEMENTS OF THE WINGS (AFTER DOTTERWEICH)

heated at one end, and, at the other, is cooled with ice. If a number of small animals, such as ants, are placed in the box, they avoid both the hot and the cold ends, and seek for a part in which a temperature prevails which suits them best.

Bees furnish a very fine example of an extraordinarily developed temperature sense. During the time when the eggs are hatching, they keep the interior of the hive at a very constant temperature of 35° (Hess, Himmer). The observed variations often lie within half a degree, that is to say, bees regulate the warmth of the hive just as exactly as mammals regulate the temperature of the blood

It goes without saying that they must possess sensory cells by means of which they perceive heat They raise the temperature of the hive apparently by muscular movements, over-heating they counteract by carrying in water and allowing it to evaporate

Nocturnal Lepidoptera regulate the temperature of the body before flying. As a result of the heat produced by muscular activity, they attain, during flight, a temperature of about 36–40° Before they fly off, they make very rapid, vibratory movements with their wings, buzzing or whirring This, as Dotterweich has recently proved, is simply to raise the temperature of the body As soon as the flight temperature is reached, they fly off. Fig. 11 represents, graphically, the raising of the body temperature during this vibration.

Very little is known, up to the present time, of heat perception in the rest of the Invertebrata. (W. v. BUD)

For the sensory function of touch in man *see* SKIN, SENSORY FUNCTIONS OF

TOUCH-ME-NOT (*Impatiens Noli-tangere*), a plant so called from the fact that the fruits are extremely explosive, the valves rolling up inwards and scattering the seeds when touched. The genus *Impatiens* (family Balsaminaceae) includes about 340 species, found in tropical and north temperate regions, and especially abundant in the mountains of India and Ceylon. Many are cultivated ornamental flowers. (*See* IMPATIENS.)

TOUL, a garrison town of north-eastern France, in the department of Meurthe-et-Moselle, 21 m. W. of Nancy on the Eastern railway. Pop. (1926) 10,113. Toul (*Tullum*) was originally capital of the Leuci, in the Belgic Confederation, and acquired great importance under the Romans. It was evangelized by St. Mansuy in the 4th century, and became one of the leading sees of north-east Gaul. After being sacked successively by Goths, Burgundians, Vandals and Huns, Toul was conquered by the Franks in 450 Under the Merovingians it was governed by counts, assisted by elective officers. The bishops became sovereign counts in the 10th century, holding only of the emperor, and for 300 years (13th to 16th centuries) the citizens maintained a long struggle against them. Together with Verdun and Metz, the town and its domain formed the territory of the Trois-Evêchés Toul was forced to yield for a time to the count of Vaudémont in the 12th century, and twice to the duke of Lorraine in the 15th Charles V. made a solemn entry into the town in 1544, but in 1545 it placed itself under the perpetual protection of the kings of France. Henry II. took possession of the Trois-Evêchés in 1552, but the territory was not officially incorporated with France till 1648 Henry IV was received in state in 1603, and in 1637 the parlement of Metz was transferred to Toul In 1700 Vauban rebuilt the fortifications of the town. In 1790 the bishopric was suppressed and the diocese united to that of Nancy. Toul capitulated in 1870.

The church of St. Étienne, which was formerly a cathedral, has a choir and transept of the 13th century; the nave and aisles are of the 14th, and the fine façade of the last half of the 15th There are two western towers. The two large lateral chapels of the nave are in the Renaissance style. South of the church there is a fine cloister of the end of the 13th century which was much damaged at the Revolution. The church of St. Gengoult, chiefly late 13th or early 14th century, has a façade of the 15th century and a 16th century cloister in Flamboyant Gothic. The *hôtel-de-ville* occupies a building of the 18th century, once the episcopal palace Toul is the seat of a sub-prefect The industries include the manufacture of porcelain, trade is in wine and brandy.

TOULON, a seaport and first-class fortress and naval station of France, department of Var, capital of the arrondissement of Toulon, on the Mediterranean, 42 m. E.S E. of Marseilles. Pop. (1926) 92,759. The Roman Telo Martius is supposed to have stood near the *lazaretto*. The town was successively sacked by Goths, Burgundians, Franks and Saracens. Until conquered by Charles of Anjou in 1259, it was under lords of its own, and entered into alliance with the republics of Marseilles and Arles. St Louis, and especially Louis XII and Francis I. strengthened its fortifications It was seized by the emperor Charles V. in 1524 and 1536. Henry IV. founded there a naval arsenal which was further strengthened by Richelieu, and Vauban made the new dock, a new enceinte, and several forts and batteries. In 1792 the royalists of the town sought the support of the English and Spanish fleets cruising in the neighbourhood. The Convention having replied by putting the town *hors la loi*, the inhabitants opened their harbour to the English. The army of the republic now (1793) laid siege to the town, and on this occasion Napoleon Bonaparte first made his name as a soldier. The forts commanding the town having been taken, the English ships retired after setting fire to the arsenal. Under the Directory Toulon became the most important French military fort on the Mediterranean; here Napoleon organized the Egyptian campaign.

The bay, which opens to the east, has two divisions, the Grande Rade and the Petite Rade; it is sheltered on the north and west by high hills, closed on the south by the peninsula of capes Sicié and Cépet, and protected on the east by a huge breakwater. The forts of St Marguerite, of Cap Brun, of Lamalgue and of St Louis to the north, and the battery of the signal station to the south, the battery of Le Salut to the east, and the forts of Balaguier and L'Aiguillette to the west protect the entrance. The bay of La Seyne lies west of the Petite Rade, and is defended by the forts of Six-Fours, Napoléon (formerly Ft. Caire), and Malbousquet, and the batteries of Les Arènes and Les Gaus. To the north of Toulon rise the defensive works of Mt. Faron and Ft. Rouge, to the east the forts of Artigues and St. Catherine, to the north-east the formidable fort of Coudon, and to the south-east that of Colle Noire, respectively dominating the highway into Italy and

the valley of Hyères with the Bay of Carqueiranne. The modern quarter lies to the north of the old town. The chief buildings are the former cathedral of St. Marie Majeure (from the 5th century Toulon was a bishop's see till 1801, when it was annexed to that of Fréjus), the church of St. Louis, the naval and military hospital, a naval school of medicine, a school of hydrography, and large barracks The imports are corn, wood, coal, hemp and salt provisions; the exports are salt, figs, raisins, almonds, oranges, cloth, bauxite ore, cork, soap and oils The principal industries, apart from the arsenal, are shipbuilding, fishing and wine-growing The interesting buildings and gardens of the hospital of St Mandrier stand on the peninsula of Cape Cépet, and near them is the *lazaretto*. Toulon is the seat of a sub-prefect, of a chamber of commerce, a board of trade-arbitrators and of a permanent maritime tribunal

Toulon is the most important of the French dockyards, and is the headquarters of the Mediterranean fleet The arsenal, which was created by Louis XIV.—Vauban being the engineer of the works—lies on the north side of the Petite Rade This is approached from the Grande Rade by passages at the north and south ends of a long breakwater which extends from the direction of Le Mourillon towards the Cépet peninsula Outside in the Petite Rade is a splendid protected anchorage for a great fleet, the whole being commanded by many forts and batteries There are four great basins (*darses*) approached from the Petite Rade—the Vieille Darse, to the east, on the side of Le Mourillon; the Darse Vauban, next to it; and the Darse de Castigneau and the Darse Missiessy, farther to the west Shipbuilding and its accessory trades are carried on at Toulon (H J F)

The Battle of Toulon.—This battle was fought off the port from which it takes its name on February 11, 1744 An allied Franco-Spanish fleet of 28 ships was in harbour, commanded by M de Court, and was being watched by a British fleet of similar size under Admiral Mathews England and Spain had been at war since 1739, but England and France, though on opposite sides, had not yet actually declared war on one another Spain was employed at this time in sending troops to North Italy for an attack on Austria's Italian possessions, and France was helping her by placing Toulon at her disposal as a base from which to operate, and also by providing about two-thirds of this fleet which was to convoy them In these circumstances, as it was his business to prevent the despatch of these troops, Mathews felt he would be justified in attacking the French as well as the Spaniards, should the former's proffered assistance with their Mediterranean fleet materialize. The combined fleet put out of Toulon on February 9, and to Mathews' surprise, made off on a southerly course If he were to follow them, he would uncover Toulon and the transports would slip out, on the other hand, if he waited for the transports, the enemy's fleet would not be brought to action. The English admiral decided in these circumstances to go after the fleet and bring it to action quickly, at any cost, and by any means, and then to double back and intercept the escaping transports. Consequently he dashed after the enemy. He himself was commanding the centre Lestock, the second-in-command, the rear, and Rowley the van.

Misunderstood Plan.—According to the fighting instructions of the day, it was Mathews' duty first, if possible, to obtain the windward position. This he did. Then, before he bore down on the enemy to what distance he considered suitable, he was so to arrange his line that the ends would be conterminous with those of the enemy, so that, when parallel battle was finally joined, each ship would be opposed to the corresponding ship in the enemy's line Clearly, however, Mathews' plan was hardly compatible with such instructions. If he was to wait until his whole line was covering the allies before attacking, he was the less likely to be back off Toulon in time to deal with the transports. Consequently, when Rowley's squadron was opposite the allied centre, and his own opposite the allied rear, Mathews signalled the attack. He was further influenced to this course by the fact that the British rear was far behind and to the east, owing, so its commander said, to variable breezes and adverse currents; in this connection, however, it must be noted that there was bad blood between Lestock and Mathews, the former was sullen, and the latter not without grave defects of temper—he was "Il Furibundo" to the Italians. Previously to the attack, Mathews had been flying the signal for the line—obviously applicable to Lestock—but when the commander-in-chief flew also the signal for battle, clearly meaning that Lestock should come up and take on the unengaged allied van before it should get about to assist the centre and rear, the second-in-command hove to and did nothing, on the grounds that Mathews was already filling his place opposite the enemy's rear and that consequently there was nothing for him to do His action can scarcely be justified except on technical grounds

Confusion of Signals.—The remainder of the British fleet was also puzzled at being ordered to attack before the whole enemy line was covered, and in this connection it must be remembered that Mathews had at his disposal no signals other than those ordering the movements laid down in the fighting instructions, and no means of conveying to his subordinates his decision that, on this occasion, these instructions did not apply. The centre bore down on the enemy eventually, but in considerable confusion Some of Rowley's squadron also attacked, but they were nervous of being doubled by the unoccupied allied van, and the leading ships correctly beat to windward to prevent this Eventually M de Court, realizing that the Spaniards who formed his rear were hard pressed, ordered his whole fleet about, and as the fresh ships came into action, Mathews broke off the battle The only prize was the *Poder*, taken by Captain Hawke

Verdicts of Courts-martial.—A record number of courts-martial followed, and it is impossible to deal with them all here Lestock was acquitted on the technical grounds indicated above, but Mathews was sentenced to dismissal from the service He had, with such ships as supported him properly, fought energetically; he had dispersed the Spanish squadron of the allied fleet, he had forced the enemy into Barcelona, and even resumed his work off Toulon He was dismissed because, in trying to force a decision in difficult circumstances, he had trespassed against the fighting instructions of his day

Bibliography.—J. S. Corbett, *Fighting Instructions*, Navy Records Society (1905), H W. Richmond, *The Navy in the War of 1739–48* (1920) (G. A. R. C.; J. G. B)

TOULOUSE, a city of south-western France, capital of the department of Haute-Garonne, 443 m S by W. of Paris by the Orléans railway, and 159 m S E of Bordeaux by the Southern railway Pop (1926), 152,580 Toulouse stands on the right bank of the Garonne, which here describes a curve round which the city extends in the form of a crescent On the left bank is the low-lying suburb of St Cyprien The river is spanned by three bridges—that of St Pierre to the north, that of St. Michel to the south, and the Pont Neuf in the centre; the last, a fine structure of seven arches. East and north of the city runs the Canal du Midi, which here joins the lateral canal of the Garonne

The church of St. Sernin or Saturnin, whom legend represents as the first preacher of the gospel in Toulouse, where he was perhaps martyred about the middle of the 3rd century, has an 11th century choir, and is the largest Romanesque basilica in existence, being 375 ft from east to west and 210 ft in extreme breadth The nave (12th and 13th centuries) has double aisles The choir (11th and 12th centuries) ends in an apse, or rather chevet, surrounded by a range of columns, marking off an aisle, which in its turn opens into five chapels Against the northern wall is an ancient *table d'autel,* which an 11th century inscription declares to have belonged to St Sernin. In the crypts are many relics, which, however, were robbed of their gold and silver shrines during the Revolution On the south there is a fine outer porch in the Renaissance style. The church was restored in the 19th century. The cathedral, dedicated to St. Stephen, has an 11th century nave and a 13th century choir, restored, the axis of which is not in a line with that of the nave. It is surrounded by 17 chapels. The western gate is flanked by a huge square tower. Over this gate there is a beautiful 13th century rose-window. The city contains other interesting old churches

The principal secular buildings are the capitole, with a long

Ionic façade built 1750–60, and the museum. The law courts stand on the site of the old Château Narbonais, once the residence of the counts of Toulouse and later the seat of the parlement of Toulouse Toulouse is singularly rich in mansions of the 16th and 17th centuries, notably the Hôtel Bernuy, a fine Renaissance building and the Hôtel d'Assézat of the same period. The Maison de Pierre has an elaborate stone façade of 1612

Toulouse is the seat of an archbishopric, of a court of appeal, a court of assizes and of a prefect. It is also the headquarters of the XVII army corps and centre of an educational division (*académie*) There are tribunals of first instance and of commerce, a board of trade-arbitrators and a chamber of commerce The educational institutions include faculties of law, medicine and pharmacy, science and letters, a Catholic institute with faculties of theology and letters, schools of veterinary science, fine arts and industrial sciences and music, and an agricultural institute Toulouse, the principal commercial and industrial centre of Languedoc, has important markets for horses, wine, grain, flowers, leather, oil and farm produce Its numerous industrial establishments include the national tobacco factory.

History.—Tolosa does not seem to have been a place of great importance during the early centuries of the Roman rule in Gaul, though in 106 B C the pillage of its temple by Q S Cepio, afterwards routed by the Cimbri, gave rise to the famous Latin proverb *habet aurum Tolosanum,* in allusion to ill-gotten gains It possessed a circus and an amphitheatre, but its most remarkable remains are to be found on the heights of Old Toulouse (*vetus Tolosa*) some 6 or 7 m to the east, where huge accumulations of broken pottery and fragments of an old earthen wall mark the site of an ancient settlement The numerous coins that have been discovered on the same spot do not date back farther than the 2nd century B C, and seem to indicate the position of a Roman trading centre then beginning to occupy the Gallic hill-fortress that, in earlier days, had been the stronghold of the native tribes dwelling on the river bank Tolosa does not seem to have been a Roman colony; but its importance must have increased greatly towards the middle of the 4th century It is entered in more than one itinerary dating from about this time, and Ausonius alludes to it in terms implying that it then had a large population. In 419 it was made the capital of his kingdom by Wallia, king of the Visigoths, and under his successors it was the centre of the great Visigothic kingdom On the defeat of Alaric II. (507) Toulouse fell into the hands of Clovis, who carried away the royal treasures Under the rule of the Merovingian kings Toulouse seems to have remained the greatest city of southern Gaul It figures prominently in the pages of Gregory of Tours and Sidonius Apollinaris About 628 Dagobert erected South Aquitaine into a kingdom for his brother Charibert, who chose Toulouse as his capital For the next 80 years its history is obscure, till we reach the days of Charles Martel, when it was besieged by Sema the leader of the Saracens from Spain (*c* 715–720), but delivered by Eudes, "princeps Aquitaniae" Its real history recommences in 780 or 781, when Charlemagne appointed his little son Louis king of Aquitaine, with Toulouse for his chief city

During the minority of the young king his tutor Chorson ruled at Toulouse with the title of duke or count. Being deposed at the Council of Worms (790), he was succeeded by William Courtnez, the traditional hero of southern France, who in 806 retired to his newly founded monastery at Gellone, where he died in 812 In the troubles of the century Toulouse suffered in common with the rest of western Europe It was besieged by Charles the Bald in 844, and taken four years later by the Normans, who in 848 had sailed up the Garonne as far as its walls About 852 Raymond I., count of Quercy, succeeded his brother Fridolo as count of Rouergue and Toulouse, it is from this noble that all the later counts of Toulouse trace their descent

Dating from the 11th century the counts of Toulouse were the greatest lords in southern France. Raymond IV, the crusader, assumed the formal titles of marquis of Provence, duke of Narbonne and count of Toulouse While Raymond was away in the Holy Land, Toulouse was seized by William IX., duke of Aquitaine, who claimed the city in right of his wife Philippa, the daughter of William IV., but was unable to hold it long (1098–1100). The rule of Raymond's son and successor Bertrand, also a crusader, was disturbed by the ambition of William IX and his grand-daughter Eleanor, who prevailed upon her husband Louis VII to support her claims to Toulouse by war. On her divorce from Louis and her marriage with Henry II, Eleanor's claims passed on to this monarch, who at last forced Raymond V to do him homage for Toulouse Raymond V., the patron of the troubadours, died in 1194, and was succeeded by his son Raymond VI, under whose rule Languedoc was desolated by the crusaders of Simon de Montfort, who occupied Toulouse in 1215, but lost his life in besieging the city in 1218 Raymond VII, the son of Raymond VI and Joan of England, succeeded his father in 1222, and died in 1249, leaving an only daughter Joan, married to Alfonso the brother of Louis IX On the death of Alfonso and Joan in 1271 the vast inheritance of the counts of Toulouse lapsed to the Crown From the middle of the 12th century the people of Toulouse seem to have begun to free themselves from the most oppressive feudal dues An act of Alphonse Jourdain (1141) exempts them from the tax on salt and wine; and in 1152 we have traces of a "commune consilium Tolosae" making police ordinances in its own name "with the advice of Lord Raymond, count of Toulouse, duke of Narbonne, and marquis of Provence"

The parlement of Toulouse was established in 1443 and was for Languedoc and southern France what the parlement of Paris was for the north During the religious wars of the 16th century the Protestants of the town made two unsuccessful attempts to hand it over to the prince de Condé After St Bartholomew's Day (1572) 300 of the party were massacred Towards the end of the 16th century, during the wars of the League, the parlement was split up into three different sections, sitting respectively at Carcassonne or Béziers, at Castle Sarrasin and at Toulouse The three were reunited in 1596. Under Francis I it began to persecute heretics, and in 1619 rendered itself notorious by burning the philosopher Vanini. The University of Toulouse owes its origin to the action of Gregory IX, who in 1229 bound Raymond VII to maintain four masters to teach theology and eight others for canon law, grammar and the liberal arts Civil law and medicine were taught only a few years later The famous "Floral Games" of Toulouse, in which the poets of Languedoc contended (May 1–3) for the prize of the golden amaranth and other gold or silver flowers, given at the expense of the city, were instituted in 1323–24 The *Académie des Jeux Floraux* still awards these prizes for compositions in poetry and prose

See L Ariste and L Brand, *Histoire populaire de Toulouse depuis les origines jusqu'à ce jour* (Toulouse, 1898). (X.)

Battle of Toulouse, 1814.—Marshal Soult, retreating eastwards after a series of defeats (*see* PENINSULAR WAR), took shelter within the defences of Toulouse The town lies on the right (east) bank of the Garonne, with a suburb, St. Cyprien, in the re-entrant angle on the left bank In 1814 it was surrounded by fortified walls, St. Cyprien having also an outer line of earthworks On the right bank the defences were (1) the walls; (2) the Languedoc canal, which covers the north and east sides, (3) the ridge of Calvinet, east of the canal; (4) the river Hers, east of Calvinet and about two miles distant from the town Wellington's plan was for Beresford's corps to attack the southern end of Calvinet ridge by way of the Caraman and Lavaur roads, while Freire's Spaniards advanced down the Albi road, captured the outlying Pujade hill, and attacked the Great Redoubt at the northern end of the ridge; to keep the defenders fully employed Hill was to demonstrate against St. Cyprien on the left bank, and Picton and Alten's Light Division against the northern defences of the town Soult's dispositions were as follows: Maransin's division held St. Cyprien; Travot's division occupied the ramparts and the eastern stretch of the canal; Darricau's division was along its northern stretch from the Albi road to the Garonne On the Calvinet ridge, Taupin was responsible for the southern end, including the La Sypière redoubts, Harpisse for Mas des Augustins, Villatte for the Great Redoubt, while Darmagnac covered the Albi road Each army numbered something under 40,000; but it must be remembered that the French *moral* at this

time was at a very low ebb. At 9 A.M. on April 10, 1814, Hill attacked St. Cyprien and during the course of the morning occupied the outer line of defences; the 3rd and Light Divisions closed up to the northern stretch of the canal and Freire gained the Pujade hill with little opposition. Wellington's plan necessitated Beresford's marching southwards three miles up the valley of the Hers, straight across the enemy's front and under direct fire of his guns The going was so heavy that it was noon before he reached the Caraman road, his men nearly exhausted and his guns stuck in the mud miles behind In spite of this he formed his corps for the attack, 6th Division on the right, 4th on the left, each in three lines. Meanwhile Freire, impatient for glory, launched a premature attack down the Albi road. After some initial success he was counter-attacked by Darmagnac and driven back with severe losses Beresford now began his advance and quickly drove Taupin's division from La Sypière, but reinforcements from the town enabled the French to form a new line in front of the canal, connecting with Mas des Augustins. Beresford paused to rest his men and wait for his guns, whereupon Picton, contrary to orders, hurled his division against the fortified canal bridges near the Garonne, and was repulsed with heavy loss Wellington now ordered Beresford and Freire to renew their attacks upon the Calvinet redoubts Freire was again repulsed, but the 6th Division, after heavy and fluctuating fighting, won possession of Mas des Augustins and the neighbouring works Upon this Soult withdrew from the remainder of the ridge and when night fell the French were behind the canal, except for two bridgeheads at its southern end Wellington spent the 11th bringing up ammunition supplies, but during that night Soult, fearful of being shut up in Toulouse, evacuated the town and took the road for Carcasonne The Allies lost 4,400 men, 1,800 being Spaniards, the French little more than 2,000 Vain losses, for Napoleon had abdicated a week previously (H L A -F.)

TOUNGOO or TAUNG-NGU, a town and district in the Tenasserim division of Burma The town is situated on the right bank of the river Sittang, 166 m N of Rangoon by rail Pop (1921) 19,332. From the 14th to the 16th century Toungoo was the capital of an independent kingdom The district has an area of 6,135 sq m., pop (1921), 381,883 The main Rangoon-Mandalay railway is the chief means of communication The rainfall is between 60 and 90 inches. Rice is the staple crop; there are some plantations of rubber Forests cover more than 5,000 sq m, of which large areas have been reserved, yielding a large revenue

TOURACOU, the name of certain birds belonging to the plantain eaters (*Musophagidae*) The term is often extended to cover the whole family, which is exclusively African.

The plantain-eaters proper comprise the genus *Musophaga* They are birds the size of a crow, with the horny base of the bill prolonged backwards over the forehead The plumage is purple, with the top of the head and primaries deep crimson and, in *M. violaca*, a white eye-streak

The Touracous number some 15 species The white-crested Touracou (*Turacus albicristatus*) inhabits Cape Colony and Natal *T persa*, from Guinea, is distinguished from the last by the purple, instead of green, wing coverts and tail The slate-brown grey Touracou (*Schizorrhis concolor*) inhabits Natal.

TOURAINE, a French province, bounded on the north by Orléanais, west by Anjou and Maine, south by Poitou and east by Berry, and corresponding approximately to the modern department of Indre-et-Loire. Touraine took its name from the *Turones,* the tribe by which it was inhabited at the time of Caesar's conquest of Gaul The capital city, Caesarodunum, was made by Valentinian the metropolis of the 3rd Lyonnaise, which included roughly the later provinces of Touraine, Brittany, Maine and Anjou The ecclesiastical province of Tours was apparently created during the episcopate of St. Martin (*fl.* 375–400), who founded the abbey of Marmoutier, near Tours, and whose tomb in the city became a celebrated shrine. Tours was included in the territory of the Visigoths, but the Tourangeans refused to adopt the Arian heresy of their conquerors, and easily accepted the conquest of the province by Clovis (*c.* 507). The possession of Touraine was constantly in dispute between different Merovingian princes, and the province enjoyed no settled peace until the reign of Charlemagne. He established Alcuin as abbot of St Martin of Tours, under whom the school of Tours became one of the chief seats of learning in Gaul From Merovingian times, the administration of Touraine was entrusted to counts appointed by the Crown. The office became hereditary in 940 or 941 with Theobald the Old. His son Odo I was attacked by Fulk the Black, count of Anjou, and despoiled of part of his territory. His grandson Theobald III, who refused homage to Henry I, king of France, in 1044, was entirely dispossessed by Geoffrey Martel of Anjou (d. 1060) and the county of Touraine remained under the domination of the counts of Anjou (*q v*) until 1204 Philip Augustus appointed William des Roches hereditary seneschal in 1204, but the dignity was ceded to the Crown in 1312 Touraine was granted from time to time to princes of the blood as an appanage of the Crown of France In 1328 it was held by Jeanne of Burgundy, queen of France, by Philip, duke of Orleans, in 1344, and in 1360 it was made a peerage duchy on behalf of Philip the Bold, afterwards duke of Burgundy Charles VII. bestowed the duchy successively on his wife Mary of Anjou, on Archibald Douglas and on Louis III of Anjou It was the dower of Mary Stuart as the widow of Francis II The last duke of Touraine was Francis, duke of Alençon (d 1584) Plessis-les-Tours had been the favourite residence of Louis XI, who granted many privileges to the town of Tours, and increased its prosperity by the establishment of the silk-weaving industry The reformed religion numbered many adherents in Touraine, who suffered in the massacres following on the conspiracy of Amboise Many Huguenots emigrated after the massacre of St. Bartholomew, and after the revocation of the Edict of Nantes the silk industry, which had been mainly in the hands of the Huguenots, was almost destroyed This migration was one of the prime causes of the extreme poverty of the province in the next century

See the quarterly publication of the *Mémoires* of the *Société archéologique de Touraine* (1842, etc) which include a *Dictionnaire géographique, historique et biographique* (6 vols, 1878–84), by J X Carre de Busserolle There are histories of Touraine and its monuments by Chalmel (4 vols 1828), by S Bellanger (1845), by Bourrasse (1858) *See* also Dupin de Saint Andre, *Hist du protestantisme en Touraine* (1885), T. A. Cook, *Old Touraine* (1892)

TOURCOING (tōōr-kwăn), a town of northern France in the department of Nord, less than a mile from the Belgian frontier, and 8 m N N E. of Lille on the railway to Ghent Pop (1926) 79,491 Famed since the 12th century for its woollen manufactures, Tourcoing was fortified by the Flemings in 1477, when Louis XI of France disputed the inheritance of Charles the Bold with Mary of Burgundy but in the same year was taken and pillaged by the French In 1794 the Republican army, under Moreau and Souham, gained a decisive victory there over the Austrians Tourcoing is practically one with Roubaix to the south, being united thereto by a tramway and a branch of the Canal de Roubaix The public institutions comprise a tribunal of commerce, a board of trade arbitrators, a chamber of commerce, an exchange and a conditioning house for textiles Together with Roubaix, Tourcoing ranks as one of the chief textile centres of France. Its chief industry is the combing, spinning and twisting of wool, spinning of cotton and the manufacture of all kinds of woollen, cotton and silk goods, notably carpets. To these industries must be added those of dyeing, the manufacture of hosiery, of textile machinery and of soap

TOURING CAR. A term widely used to describe an automobile of open body type with a folding top, removable side curtains and two fixed seats In the United States (1929), the word "phaeton" seems to be preferred to describe such a body, leaving the name touring car for any automobile used for touring. (*See* PHAETON.)

TOURMALINE, a mineral of interest from several points of view, but of no commercial value, except occasionally when used as a gem-stone. The name is from the Cingalese *toramalli,* brown gem-stones having come from Ceylon early in the 18th century. The mineral is of interest chemically on account of its complex composition, containing, perhaps, a greater variety of chemical elements than any other mineral, and these are present

in very variable proportions. Many attempts have been made to arrive at a general formula to express the composition. The one now generally accepted is that of S L Penfield and H W. Foote (1899), who regarded the several varieties of tourmaline as salts of a hypothetical alumino-borosilicic acid $H_9Al_3(BOH)_2Si_4O_{19}$. Here hydrogen is partly, but not wholly, replaced by aluminium, ferric and ferrous iron, chromium, manganese, magnesium, calcium, sodium, potassium, lithium, etc , and fluorine is usually also present in small amounts Rather than a single species, tourmaline thus represents an extensive series of isomorphous minerals, but the sub-division into species is not practicable According to the predominance of certain elements, a chemical distinction has been made between iron-tourmaline, magnesium-tourmaline and alkali-tourmaline

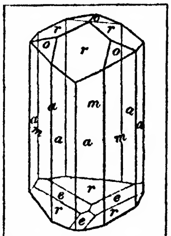

FIG. 1.—CRYSTAL OF TOURMALINE SHOWING HEMIMORPHIC DEVELOPMENT

All crystals of tourmaline belong to the ditrigonal pyramidal (hemimorphic-hemihedral) class of the rhombohedral system, and no variation can be detected in the interfacial angles corresponding with the wide range in chemical composition. The crystals are of interest in showing a different development of faces at the two ends, the vertical trigonal axis, or principal axis, being uniterminal or polar. At the upper end in fig 1 are two trigonal pyramids *r* and *o*, and at the lower end the trigonal pyramids *r* and *e*. The crystals are usually prismatic in habit with one hexagonal prism *a* and a trigonal prism *m*, and between the two there may be several ditrigonal prisms each of six faces All these prism faces are deeply striated or furrowed parallel to the vertical axis, so much so that the cross-section is usually triangular with curving convex sides This characteristic feature enables the mineral to be readily distinguished from others of similar appearance.

Another interesting feature of tourmaline is shown in the pyro-electrical properties, which are intimately related to the hemimorphic or polar development of the crystals mentioned above. When a crystal is slightly warmed, one end becomes charged with positive electricity and the other end acquires a negative charge. On cooling these charges are reversed This is well shown by dusting a cooling crystal over with a mixture of red-lead and sulphur, when the yellow sulphur is attracted to the positively charged end and the red lead to the negatively charged end A faceted gem-stone of tourmaline may be tested in this way. Tourmaline also shows the related phenomenon of piezoelectricity When a plate cut perpendicular to the principal axis is subjected to variations of pressure it develops positive and negative charges on the two surfaces This property can be made use of for detecting small variations in pressure, as in depth-sounding apparatus.

The optical properties are also of exceptional interest. A ray of light entering a crystal of tourmaline is split up into two rays, one, the ordinary ray, vibrating perpendicular to the principal axis, and the other, the extraordinary ray, vibrating parallel to this axis Coloured crystals are very strongly dichroic, the ordinary ray being almost completely absorbed. Plates cut parallel to the principal axis of the crystal, therefore, allow only the extraordinary ray to pass through, and if two such plates are placed in crossed position the light is entirely cut out. A pair of such plates form a very simple polarizing apparatus known as tourmaline tongs. The crystals are optically uniaxial and negative, and the refractive indices vary with the chemical composition, for the ordinary ray $\omega = 1{\cdot}6315$–$1{\cdot}6854$, and for the extraordinary ray $\epsilon = 1{\cdot}6123$–$1{\cdot}6515$ for sodium-light The specific gravity shows a corresponding range from 3·0 to 3·2 The hardness is 7·5.

In general appearance, tourmaline is extremely variable. It may be quite colourless and water-clear, black and opaque, or various shades of red, yellow, brown, green or blue. Some crystals show very strikingly bands of different colours. The coloured varieties when clear and of good quality are cut as gem-stones under the names rubellite or "Siberian ruby," "Brazilian emerald," indicolite, etc. In addition to well-formed crystals, the mineral may take the form of rounded triangular rods or fine needles, which are often aggregated in bundles or radiating groups, or it may form compact granular masses. A common form, especially in the Cornish tin mines, is as bundles of black needles, this form being known as *schorl* (German, *Schörl*).

Tourmaline generally occurs in connection with granitic rocks, and it is often an indication of the presence of tin-ore It would appear to have originated in most cases by the interaction of boron-bearing emanations from the granite magma on the surrounding rocks and minerals The best crystals are found in pegmatite veins and in metamorphic limestones in contact with granite masses Being resistant to weathering processes the mineral accumulates in detrital deposits and in sedimentary rocks. Gem tourmaline comes from the gem-gravels of Ceylon and is quarried in pegmatite veins in the Ural mountains, California and Madagascar. (L J S.)

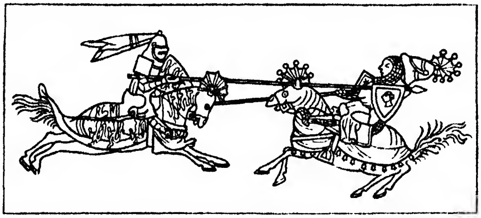
TOURNAI (Flemish *Doornik*), city, province of Hainaut, Belgium, on the Scheldt. Pop. (1925) 36,266 The cathedral of Notre-Dame dates from 1030, the nave is Romanesque of the middle of the 12th century, with much pointed work. The transept was added in the 13th century. The first choir was burned down in 1213, but was rebuilt in 1242 at the same time as the transept, and is a superb specimen of pointed Gothic There are five towers with spires. There are several old pictures of merit, and the shrine of St. Eleuthère, the first bishop of Tournai in the 6th century, is a remarkable product of the silversmith's art The belfry on the Grand Place, the oldest in Belgium, was built in 1187, partly reconstructed in 1391 and finally restored and endowed with a steeple in 1852. The church of St Quentin in the same square as the belfry is almost as ancient as Notre-Dame In the church of St Brice is the tomb of Childeric discovered in 1655 Among the relics were three hundred small golden models of bees These were removed to Paris, and when Napoleon was crowned emperor a century and a half later he chose Childeric's bees for the decoration of his coronation mantle In this manner the bee became associated with the Napoleonic legend just as the lilies were with the Bourbons. The Pont des Tours over the Scheldt, with towers at each end, was built in 1290, and some old houses still in occupation date back to the 13th century On the Grand Place is the fine statue of Christine de Lalaing, princess d'Epinoy, who defended Tournai against Parma in 1581. Tournai carries on a large trade in carpets (called Brussels), bonnet shapes, corsets and fancy goods generally

The actual site was occupied under Julius Caesar and called *civitas Nerviorum* or *castrum Turnacum*. In the reign of Augustus, Agrippa fixed the newly mixed colony of Suevi and Menapii at Tournai In the 5th century the Franks seized Tournai, and Merovaeus made it the capital of his dynasty. This it remained until the subdivision of the Frank monarchy among the sons of Clovis. When feudal possessions, instead of being purely personal, were vested in the families of the holder after the death of Charlemagne, Tournai was specially assigned to Baldwin of the Iron Arm by Charles the Bald, whose daughter Judith he had abducted, on receiving the hereditary title of count of Flanders During the Burgundian period it was the residence of Margaret of York, widow of Charles the Bold, and the pretender Perkin Warbeck, whom she championed, if not born there, was the reputed son of a Jew of Tournai. In the early 16th century Tournai was an English possession for a few years and Henry VIII. sold it to Francis I It did not long remain French, for in 1521 the count of Nassau, Charles V.'s general, took it and added it to the Spanish provinces

TOURNAMENT or **TOURNEY.** Of the mediaeval definitions of the tournament given by Du Cange (*Glossarium, s.v.* "Tourneamentum"), the best is that of Roger of Hoveden, who described tournaments as "military exercises carried out, not in the spirit of hostility (*nullo interveniente odio*), but solely for practice and the display of prowess (*pro solo exercitio, atque ostentatione virium*)." It apparently originated in France, and more than one chronicler records the violent death, in 1066, of a French baron, Geoffroi de Preulli, who, according to the testimony of his contemporaries, "invented tournaments." In England, at least, the

tournament was counted a French fashion, Matthew Paris calling it *conflictus gallicus*.

By the 12th century the tournament notwithstanding the condemnation of the Council of the Lateran, had grown so popular in England that Henry II. found it necessary to forbid the sport which gathered in one place so many barons and knights in arms In that age we have the famous description by William FitzStephen of the martial games of the Londoners in Smithfield He



ENGLISH KNIGHTS TILTING WITH LANCES IN A TOURNAMENT FROM THE LOUTERELL PSALTER, AN ILLUSTRATED MANUSCRIPT OF THE 14TH CENTURY

tells how on Sundays in Lent a noble train of young men would take the field well mounted, rushing out of the city with spear and shield to ape the feats of war. Divided into parties, one body would retreat, while another pursued striving to unhorse them The younger lads, he says, bore javelins disarmed of their steel, by which we may know that the weapon of the elders was the headed lance William of Newbury tells us how the young knights, balked of their favourite sport by the royal mandate, would pass over sea to win glory in foreign lists Richard I relaxed his father's order, granting licences for tournaments, and Jocelin of Brakelond has a long story of the great company of cavaliers who held a tournament between Thetford and Bury St Edmund's in defiance of the abbot From that time onward unlicensed tourneying was treated as an offence against the Crown, which exacted heavy fees from all taking part in them even when a licence had been obtained

In 1299 life and limb were declared to be forfeit in the case of those who should arrange a tourney without royal licence, and offenders were to be seized with horse and harness As the tournament became an occasion for pageantry and feasting, new reason was given for restraint, a simple knight might beggar himself over a sport which risked costly horses and carried him far afield Jousters travelled from land to land, offering and accepting challenges Thus Edward I, before coming to the throne, led 80 knights to a tournament on the Continent Before the jousts at Windsor on St George's day in 1344 heralds published in France, Scotland, Burgundy, Hainault, Flanders, Brabant and the domains of the emperor the king's offer of safe conduct for competitors At the weddings of princes and magnates and at the crowning of kings the knights gathered to the joustings, which had become as much a part of such high ceremonies as the banquet and the minstrelsy

Regulations.—About 1292 a "Statute of Arms for Tournaments" enacted new laws Swords with points were not to be used, nor pointed daggers, nor club nor mace. None was to raise up a fallen knight but his own appointed squires, clad in his device The squire who offended was to lose horse and arms and lie three years in gaol Disputes were to be settled by a court of honour of princes and earls. That such rules were needful had been shown at Rochester in 1251, where foreign knights were beaten by the English and so despitefully treated that they fled to the city for refuge On their way the strangers were faced by another company of knights who handled them roughly and spoiled them, thrashing them with staves in revenge for the doings at a Brackley tournament. Even as early as the 13th century some of these tournaments were mere pageants of horsemen For the Jousts of Peace held at Windsor Park in 1278 the sword-blades were of whalebone and parchment, silvered: the helms were of boiled leather and the shields of light timber. But the game could make rough sport Many a tournament had its tale of killed and wounded in the chronicle books. We read how Roger of Lemburn struck Arnold de Montigny dead with a lance thrust under the helm. The first of the Montagu earls of Salisbury died of hurts taken at a Windsor jousting, and in those same lists at Windsor the earl's grandson Sir William Montagu was killed by his own father. William Longéspee in 1256 was so bruised that he never recovered his strength, and he is among many of whom the like is written, injuries were often caused when dismounted adversaries continued the combat on foot Blunted or "rebated" lance-points came early into use, and by the 14th century the coronall or cronell head was often fitted in place of the point After 1400 the armourers began to devise harness with defences specially wrought for service in the lists But the joust lost its chief perils with the invention of the tilt, which, as its name imports, was at first a cloth stretched along the length of the lists The cloth became a stout barrier of timber, and in the early 16th century the knight ran his course at little risk. Locked up in steel harness, reinforced with the grand-guard and the other jousting pieces, he charged along one side of this barrier, seeing little more through the pierced sight-holes of the helm than the head and shoulders of his adversary His bridle arm was on the tilt-side, and thus the blunted lance struck at an angle upon the polished plates Mishaps might befall At the close of the famous tournament which formed part of the rejoicings for the peace of Cateau-Cambresis in 1559 Henry II of France died from the stroke of Gabriel de Montgomeri, who failed to cast up in time the truncheon of his splintered lance The result of this tragedy was a considerable diminution in the popularity of the tournament But the 16th century tournament was, in the main, a bloodless meeting, as befitted a spectacle arranged as much for the delectation of women as of men Prizes, usually consisting of arms and armour, rich robes and great silver vessels were at the close presented to the victors by the Lady of the Tournament

Pageantry.—In the 15th century the tournament had the aspect of a pageant. The great meeting at Bruges, when the jousting of the Knights of the Fleece was part of the pageant of the Golden Tree, the Giant and the Dwarf, may stand as a magnificent example of many such gay gatherings When Henry VIII. was scattering his father's treasure the pageant had become an elaborate masque For two days after the crowning of the king at Westminster Henry and his queen viewed from the galleries of a fantastic palace set up beside the tilt-yard a play in which deer were pulled down by greyhounds in a paled park, in which the Lady Diana and the Lady Pallas came forward, embowered in moving castles, to present the champions Such costly shows fell out of fashion after the death of Henry VIII ; and in England the tournament remained, until the end, a martial sport. In France it degenerated to the carrousel, which became an unmartial display

The tournament was, from the first, held to be a sport for men of noble birth, and on the Continent, where nobility was more exactly defined than in England, the lists were jealously closed to all combatants but those of the privileged class In the German lands, questions as to the purity of the strain of a candidate for admission to a noble chapter were often settled by appeal to the fact that this or that ancestor had taken part in a tournament. Konrad Grunenberg's famous heraldic manuscript shows us the *Helmschau* that came before the German tournament of the 15th century—the squires carrying each his master's crested helm, and a little scutcheon of arms hanging from it, to the hall where the king of arms stands among the ladies and judges each blazon

The Eglinton Tournament.—An attempt to revive the tourney was made at Eglinton castle Ayrshire, in 1839 The inception of the idea was due to Archibald, 13th Earl of Eglinton, who found an ideal setting for his tournament in the grounds of Eglinton castle On Aug 28, 1839, the lists were dressed in the park Each knight, with his esquires and attendants, had a separate pavilion The lists were splendidly decorated and richly hung, and temporary adornments of Westminster Abbey at the then recent coronation were again used At Lord Eglinton's request many of the ladies wore the costume of the 14th and 15th centuries The marquess of Londonderry was "King of the Tournament" and Lady Seymour, afterwards duchess of Somerset, was "Queen of Love and Beauty." The official list contained the names of 15 knights:—The earl of Eglinton, the marquess of Waterford, the

earl of Craven, the earl of Cassilis, Viscount Alford, Viscount Glenlyon, the hon Capt Gage, the hon. Mr Jerningham, Capt. Fairlie, Sir Frederick Johnstone, Sir Francis Hopkins, Capt Beresford, Charles Lamb, C Boothby and Mr. Lechmere. They were in armour and carried lances. The crown of victory was bestowed upon Lord Eglinton. The second day there was a series of mimic tilts on foot and under cover between Prince Louis Napoleon, afterwards Napoleon III, and Charles Lamb, both of whom were in armour On the third day there was a series of "tourneys" in which eight knights, armed with swords, were engaged A good description of the Eglinton tournament will be found in Chapters 59 and 60 of Disraeli's famous novel, *Endymion*.

When Prince Humbert, afterwards Humbert I, King of Italy, was married at Turin in 1868 to Princess Margherita of Savoy, the festivities included a tournament. The Royal Naval and Military Tournament which has been held annually in London since 1880 consists of a series of displays of skill in arms, in the largest sense of the phrase, but differs widely from the mediaeval tourney

TOURNEUR, CYRIL (*c* 1575–1626), English dramatist, was perhaps the son of Captain Richard Turnor, water-bailiff and subsequently lieutenant-governor of Brill in the Netherlands Cyril Tourneur also served in the Low Countries, for in 1613 there is a record made of payment to him for carrying letters to Brussels. He enjoyed a pension from the government of the United Provinces, possibly by way of compensation for a post held before Brill was handed over to the Dutch in 1616 In 1625 he was appointed by Sir Edward Cecil, whose father had been a former governor of Brill, to be secretary to the council of war. This appointment was cancelled by Buckingham, but Tourneur sailed in Cecil's company to Cadiz On the return voyage from the disastrous expedition he was put ashore at Kinsale with other sick men, and died in Ireland on Feb 28, 1626

Tourneur's fame rests on two plays, *The Revenger's Tragedy* (pr. 1607) and *The Atheist's Tragedy* (pr 1611) Of these Swinburne, in an article contributed to the 9th ed of the *Encyclopædia Britannica,* wrote as follows

"The singular power, the singular originality and the singular limitation of his genius are all equally obvious in *The Atheist's Tragedy*, a dramatic poem no less crude and puerile and violent in action and evolution than simple and noble and natural in expression and in style. The executive faculty of the author is in the metrical parts of his first play so imperfect as to suggest either incompetence or perversity in the workman; in *The Revenger's Tragedy* it is so magnificent, so simple, impeccable and sublime that the finest passages of this play can be compared only with the noblest examples of tragic dialogue or monologue now extant in English or in Greek There is no trace of imitation or derivation from an alien source in the genius of this poet. . . . As a playwright, his method was almost crude and rude in the headlong straightforwardness of its energetic simplicity; as an artist in character, his interest was intense but narrow, his power magnificent but confined; as a dramatic poet, the force of his genius is great enough to ensure him an enduring place among the foremost of the followers of Shakespeare"

BIBLIOGRAPHY—The complete list of his extant works runs: *The Atheists Tragedie; or, The Honest Man's Revenge* (1611), *A Funerall Poeme Upon the Death of the Most Worthie and True Soldier, Sir Francis Vere, Knight* . . (1609), "A Griefe on the Death of Prince Henrie, Expressed in a Broken Elegie . .," printed with two other poems by John Webster and Thomas Heywood as *Three Elegies on the most lamented Death of Prince Henry* (1613); *The Revengers Tragaedie* (1607 and 1608), and an obscure satire, *The Transformed Metamorphosis* (1600)

The Revenger's Tragedy was printed in Dodsley's *Old Plays* (vol iv, 1744, 1780 and 1825), and in *Ancient British Drama* (1810, vol ii) The best edition of Tourneur's works is *The Plays and Poems of Cyril Tourneur, edited with Critical Introduction and Notes*, by J. Churton Collins (1878). *See* also the two plays printed with the masterpieces of Webster, with an introduction by J A. Symonds, in the "Mermaid Series" (1888 and 1903) No particulars of Tourneur's life were available until the facts given above were abstracted by Mr Gordon Goodwin from the *Calendar of State Papers* ("Domestic Series," 1628–1629, 1629–1631, 1631–1633) and printed in the *Academy* (May 9, 1891) A critical study of the relation of *The Atheist's Tragedy* to *Hamlet* and other revenge-plays is given in Professor A. H. Thorndike's "Hamlet and Contemporary Revenge Plays" (*Publ. of the Mod Lang Assoc*, Baltimore, 1902). For the influence of Marston on Tourneur *see* E E Stoll, *John Webster* . . . (1905, Boston, Massachusetts), pp. 105–116.

TOURNON, a town of south-western France, capital of an arrondissement in the department of Ardèche, on the right bank of the Rhône, 58 m. S. of Lyons by rail Pop (1926) 3,740 Tournon preserves a gateway of the 15th century and other remains of fortifications and an old castle used as town hall, court-house and containing a Gothic chapel. The church of St Julian dates chiefly from the 14th century. Tournon had its own counts as early as the reign of Louis I

TOURS, a town of France, capital of the department of Indre-et-Loire, 145 m S W. of Paris by rail Pop (1926) 73,109

Tours (*see* TOURAINE), under the Gauls the capital of the Turones or Turons, originally stood on the right bank of the Loire, a little above the village of St Symphorien At first called *Altionos*, the town was afterwards known as *Caesarodunum* The Romans removed the town from the hill where it originally stood to the left bank of the river

Tours became Christian about 250 through the preaching of Gatien, who founded the bishopric The first cathedral was built 100 years later by St Litorius The bishopric became an archbishopric when Gratian made Tours the capital of Lugdunensis Tertia, though the bishops did not adopt the title of archbishop till the 9th century. In the 5th century the official name of Caesarodunum was changed to *Civitas Turonorum* St Martin, the apostle of the Gauls, was bishop of Tours in the 4th century

Affiliated to the Armorican confederation in 435, the town fell to the Visigoths in 473 It became part of the Frankish dominions under Clovis At the end of the 6th century the bishopric was held by St Gregory of Tours Tours grew rapidly in prosperity under the Merovingians, but abuse of the right of sanctuary led to great disorder Charlemagne re-established discipline in the disorganized monastery and set over it the learned Alcuin, who established one of the oldest public schools of philosophy and theology. The arts flourished at Tours in the middle ages and the town was the centre of the Poitevin Romanesque school of architecture. The abbey was made into a collegiate church in the 11th century, and was for a time affiliated to Cluny, but soon came under the direct rule of Rome, and for long had bishops of its own The suburb in which the monastery was situated became important under the name of Martinopolis The Normans pillaged it in 853 and 903. Walls were erected from 906 to 910, and the name was changed to that of Châteauneuf.

In the 14th century Tours was united to Châteauneuf within a common wall, of which a round tower, the Tour de Guise, remains, and both towns were put under the same administration The numerous and long-continued visits of Charles VII, Louis XI, who established the silk-industry, and Charles VIII during the 15th century favoured commerce and industry In 1562 Tours suffered from the violence of both Protestants and Catholics

In the 17th and 18th centuries it was the capital of the government of Touraine Its manufactures, of which silk weaving was the chief, suffered from the revocation of the Edict of Nantes (1685) In 1772 its mint, whence were issued the "livres" of Tours, was suppressed During the Revolution the town formed a base of operations of the Republicans against the Vendeans

Tours lies on a flat tongue of land between Loire and Cher just above their junction. The right bank of the Loire is bordered by hills at the foot of which lie St Cyr and St. Symphorien. The river is crossed by two suspension bridges.

St. Gatien, the cathedral of Tours, dates from the 12th to the 16th centuries The lower portions of the west towers belong to the 12th century, the choir to the 13th century; the transept and east bays of the nave to the 14th; the remaining bays, a cloister on the north, and the façade, decorated in the Flamboyant style, to the 15th and 16th centuries, the upper part of the towers being in the Renaissance style of the 16th century. In the choir there is fine 13th century stained glass. The 16th century tomb of the children of Charles VIII, is attributed to the brothers Juste. The square tower of the church of St. Julien is Romanesque, the rest being in the early Gothic style of the 13th century, with

the exception of two apses added in the 16th century. Two towers and a Renaissance cloister are the chief remains of the celebrated basilica of St Martin. Two other churches are Notre-Dame la Riche, originally built in the 13th century, rebuilt in the 16th, and magnificently restored in the 19th century; and St. Saturnin of the 15th century. Of the old houses of Tours the hôtel Gouin and that wrongly known as the house of Tristan l'Hermite (both of the 15th century) are the best known. Tours has a valuable library, including among its mss. a gospel of the 8th century on which the kings of France took oath as honorary canons of the church of St. Martin. Balzac was a native of Tours. Tours is the seat of an archbishop, a prefect, and a court of assizes, and headquarters of the IX. Army Corps, and has tribunals of first instance and of commerce, a board of trade-arbitrators and a chamber of commerce.

There are silk factories and important printing works, steel works, iron and tin foundries and factories for automobiles, machinery, oil, cement, stained glass, boots and shoes, porcelain and other goods. A considerable trade is carried on in the wine of the district and in brandy, dried fruits and confectionery.

BATTLE OF TOURS

The battle of Tours (A.D. 732), sometimes called the battle of Poitiers, marks the turning point in the northern advance of the Moors; the victory of the Franks checked once and for all the expansion of Islam in western Europe. In 711 the Arabs had crossed the Straits of Gibraltar and conquered the weak Visigothic kingdom of Spain, a few years later they crossed the Pyrenees, and in 720 captured Narbonne, which became the base for their further progress into Gaul, where the wealth of the churches and monasteries offered a powerful inducement. The plan of extending their power to the north was rendered more possible by the political rivalry which subsisted betweeen the dukes of Aquitaine and the Merovingian Mayors of the Palace. However, in 720, the year in which the Arab attacks began in earnest, Eudo, duke of Aquitaine, had made his peace with Charles Martel, and was therefore free to deal with the impending danger. In 721 he relieved Toulouse, which was being besieged, and won a decisive victory over the Arabs. But after a short respite the attack was renewed in 725. A strong army crossed the eastern Pyrenees, captured Carcassonne and Nîmes, and occupied the greater part of the province of Septimania. In the same year they made a raid into Burgundy and destroyed the city of Autun. Internal dissensions among the Arabs themselves, the incessant hostility between the Ma'ddites and the Yemenites, prevented them, however, from following up these successes, and it was not until the appointment in 731 of the popular and energetic governor of the Yemenite party, 'Abd-ar-Raḥmān, that the offensive was resumed. The situation in Gaul was favourable for the enterprise, for war had once more broken out between Eudo and Charles. With a large army 'Abd-ar-Rahmān crossed the Pyrenees and captured and burnt Bordeaux. Eudo, who hastened to check his advance, was defeated, with the loss of the greater part of his army, between the Garonne and the Dordogne. The Arabs pressed forward, plundering as they went, along the line of the Roman road which ran northward from Bordeaux through Poitiers to Orleans. At Poitiers they destroyed the basilica of St Hilary; their next objective was Tours, whither they were attracted by the immense riches of the famous church of St. Martin. But before they reached it they were met by Charles, to whom Eudo, despite his previous hostility, had fled for assistance after his defeat.

Charles, at the head of a large army, engaged with the enemy south of Tours, perhaps at the little town of Cenon, near the junction of the Clain and the Vienne, and not far north of Old Poitiers (*see* the inset map in Spruner-Menke, *Hand-Atlas*, Plate 29). For seven days the two armies stood facing each other. Then on a Saturday in October the serious fighting began. Charles had taken up a defensive position in close formation. It was the moral and physical superiority of the Teutonic race over the Muslims that won the day. The light Arab cavalry broke before the "immovable wall" of Frankish soldiers who stood, we are told, firm "as a rock of ice" (Isidorus Pacensis). They were hurled back with heavy loss; 'Abd-ar-Rahmān himself was killed on the field. Fighting continued till nightfall; and when, on the next morning, the Franks prepared to resume the battle, they found the Arab tents deserted. The Arab losses were very severe.

The battle of Tours is commonly regarded as one of the decisive battles of the world's history. In a sense this is true. It dealt a decisive check to the advance of the Arabs into Gaul. It removed an imminent peril, a constant menace. But there were causes other than Charles's victory which in part account for the cessation of the Arab advance. The revolt of the Berbers in North Africa was as decisive a factor as the battle of Tours in putting an end to the advance of the Arabs into western Europe.

TOURVILLE, ANNE-HILARION DE COTENTIN

(or COSTANTIN), COMTE DE (1642–1701), French admiral and marshal of France, was the son of César de Cotentin, or Costantin, who held offices in the household of the king and of the prince of Condé. Destined by his family to enter the Order of Malta, he served for eleven years with the galleys of the Order against the Barbary pirates. In 1667 he was incorporated in the corps of officers of the French Royal navy and in 1689 he left the Order. In the French navy he served in the Mediterranean for some years. In 1670, Tourville commanded the "Page" (50), in the squadron of the comte d'Estrées (1624–1707) sent to co-operate with the duke of York against the Dutch. He was present at the battle of Solebay (June 7, 1672), and in the action on the coast of Holland in the following year, when Prince Rupert commanded the English fleet. When England withdrew from the alliance, the scene of the naval war was transferred to the Mediterranean, where Holland was co-operating with the Spaniards. Tourville served under Abraham Duquesne in his battles with De Ruyter. By this time he was known as one of the best officers in the service of King Louis XIV. By 1689 he had been promoted lieutenant-général des armées navales, and was named vice-admiral du Levant or of the East. In June of that year he became commander-in-chief of the French naval forces in the war against England and her continental allies.

From this time till the failure of his resources compelled King Louis XIV. to withdraw his fleets from the sea, Tourville continued to command the naval war in the Channel and the Atlantic. His conduct and example during this period were the source of the system of manoeuvring to gain an advantage by some method other than plain fighting. In 1690 he had an opportunity which might well have tempted the most cautious, and he missed it out of sheer care to keep his fleet safe against all conceivable chances, aided perhaps by a pedantic taste for formal, orderly movement. He was opposed in the channel by the allies, who had only fifty-six ships, while his own force was from seventy to eighty sail strong. He was feebly attacked by Admiral Arthur Herbert, earl of Torrington, off Beachy Head on July 10. The Dutch ships in the van were surrounded. The allies retreated in disorder, and Tourville followed in "line of battle" which limited his speed of pursuit to that of his slowest ship. In 1692 the Mediterranean fleet having failed to join him, he was faced by a vastly superior force of the allies. The French king had prepared a military force to invade England, and Tourville was expected to prepare the way. He made a resolute attack on the centre of the allies on May 29, off Cape Barfleur, and drew off before he was surrounded. This action, with the pursuit of the following days, made up what is called "the battle of La Hogue." His flagship the "Soleil Royale" and fifteen other ships were cut off and destroyed. In 1693 he was again at sea with a great fleet, and had a chance to capture the Smyrna convoy off Gibraltar. Again he kept his fleet in battle order, and a large part of the convoy escaped. Tourville was made Marshal of France in 1693. He died in Paris in 1701.

TOUSSAINT L'OUVERTURE (or LOUVERTURE), **PIERRE-DOMINIQUE** (*c.* 1746–1803), one of the liberators of Haiti, claimed to be descended from an African chief. His first surname Breda was afterwards changed to L'Ouverture in token of his valour in causing a gap in the ranks of the enemy. He obtained his master's confidence and was made superintendent of the other negroes on the plantation After the insurrection of 1791 he joined the insurgents and acted as physician to the forces. His rapid rise aroused the jealousy of Jean François, who caused his arrest on the ground of his partiality to the whites. He was liberated by the rival insurgent chief Baisson, and a partisan war ensued, but after the death of Baisson he placed himself under the orders of Jean François Subsequently he joined the Spaniards, but, when the French government ratified the act declaring the freedom of the slaves, he came to the aid of the French In 1796 he was named commander-in-chief of the armies of St Domingo, but, having raised and disciplined a powerful army of negroes, he made himself master of the whole country, renounced the authority of France, and announced himself "the Buonaparte of St. Domingo." He was captured by the French and died in the prison of Joux, near Besançon, on April 27, 1803

See Toussaint l'Ouverture's own *Mémoires*, with a life by Saint Remy; (1850), Gragnon-Laconte, *Toussaint Louverture* (1887); Scholcher, *Vie de Toussaint Louverture* (1889), and J. R. Beard, *Life of Toussaint Louverture* (1853).

TOUT, THOMAS FREDERICK (1855–), British historian, was born in London on Sept. 28, 1855, and educated at St. Olave's school, Southwark, and at Balliol college, Oxford. In 1881 he was appointed professor of history at St. David's college, Lampeter, and from 1890 to 1925, held a similar appointment at Manchester university. He was a fellow of Pembroke college, Oxford, from 1883 to 1890. He has taken a prominent part in the work of various historical societies and educational committees, and in 1911 was elected fellow of the British Academy. In 1925 he was elected president of the Royal Historical Society, and from 1927 to 1928 was messenger lecturer at Cornell university

His works include *History of England for Schools* (with Prof. York Powell), vol iii. (1890); vol. ii. (1898); *The Empire and the Papacy* (1898). He was first editor with H. Johnstone of *Select Trials of the Judges and Ministers, 1289–92* (Camden Series, *Royal Hist. Soc*, 1906); and has written *Chapters in the Administrative History of Mediaeval England* (vols i. and ii, 1920); *France and England, their Relations in the Middle Age and Now* (1922); and many school text books and articles in historical reviews.

TOVEY, DONALD FRANCIS (1875–), English pianist, composer and writer on music, was born on July 17, 1875, at Eton, where his father, the Rev. Duncan Charles Tovey, was a master. He was trained as a pianist by Sophie Weiss In 1900 he definitely took up music as a career and began to give recitals, in which his own compositions were included, in London and on the Continent Since 1914 he has been Reid professor of music at Edinburgh university. The Reid orchestral concerts, which he conducts, owe their existence to his initiative. He has contributed a large number of articles to the present edition of the *Encyclopædia Britannica*.

The orchestral compositions include a symphony in D, performed at Aix-la-Chapelle in 1913, a pianoforte concerto in A, prelude and entr'actes for Maeterlinck's *Aglavaine et Sélysette* (for string orchestra), and an opera, *The Bride of Dionysus* to R. C. Trevelyan's text In chamber music he has written two sonatas for violin alone; a sonata for two violoncellos; a pianoforte trio and a quintet; a trio in C minor for pianoforte, clarinet and horn; two string quartets; variations on a theme by Gluck for flute and strings He has also written three anthems and 25 rounds for equal voices.

TOWER, the term given to a lofty building originally designed for defence, hence, any structure whose height is its most important dimension, whether isolated or forming part of another building. The two earliest uses of lofty buildings were military and religious; in the one case constructed to give a raised platform from which a defending force could advantageously discharge missiles upon an attacking force, at the same time remaining protected from it; in the other case, always in connect with sun, moon or star worship, apparently in the effort to r the worshipper or the priest as near heaven as possible.

Military.—The Mesopotamian peoples seem to have built first highly developed masonry towered fortifications. Thus o tablet in the lap of the famous statue of Gudea, the king Lagash (*c.* 2700 B.C), now in the Louvre, there is a represer tion of a fort with towers and gates. The Egyptians used tow less frequently, but certain remains exist in which the Asian t appears and the palace pavilion of Amenhotep at Medinet has projecting towers of Assyrian type. The Greek world m a less definite use of towers. In Roman times, however, tow formed an integral part of every developed fortification, and w especially important on the city walls, as can be seen in m examples, especially at Pompeii and in the wall of Aurelian Rome. In Constantinople successive emperors merely follo Roman tradition and the existing ruins of the walls origin built by Theodosius reveal many analogies to similar Ron work, with their boldly projecting, square, battlemented tow Towers with curved fronts are also occasionally found, especi in connection with gates (*q v*).

In the mediaeval period, from the 13th century on, the milit tower received its greatest development, which found express in such city walls as those of Aigues Mortes and Carcassor both dating largely from the latter part of the 13th century, in such châteaux as Coucy (13th century) or Pierrefonds (1 century) The greatest development of the defensive tower through its use as the keep (*q.v*) or donjon (*q.v.*), such as mediaeval White Tower of the Tower of London (11th centu or the famous round tower of Coucy It is probably from use of the tower as a keep that the word occurs often in ho names in England, such as Houghton Tower Meanwhile, many important towns in mediaeval Italy noble families e tried to have its own tower as a place of refuge in time of f tional strife These towers were extremely high and often isolat with only a small entrance and a few small openings.

In the Near East, the great towers of the fortifications b on either side of the Bosporus at Rumeli Hissar and An Hissar, during the siege of the city (middle 15th century) still landmarks In China great masonry towers crown each g of a city wall, topped with garrison buildings that give much ac tional height; towers of a simpler and strangely European t form the most conspicuous features of the famous Great Wall China.

With the appearance of firearms, and particularly of la cannon, the use of towers as fortifications practically vanish (*See* FORTIFICATION AND SIEGECRAFT.)

Religious.—Towers built for religious purposes appear in early developed form in the Chaldean ziggurats (*q.v.*)—the gr stepped pyramids, with stairs or inclined planes connecting levels, and an open terrace with an altar or a shrine at the t which were attached to nearly every Chaldean and Assyrian te ple. Similar high buildings, the so-called pyramids, were f quently associated with temples in ancient Mexico and Cent America. The early Persians seem also to have used raised p forms on small towers in connection with their fire worship. the classic world towers do not appear as important religi buildings, and it was not until the 8th century, and probably w the wide introduction of bells that they came to be associa with churches. (*See* CAMPANILE.)

By the end of the 11th century the use of church towers almost universal. In France the earliest examples are placed the crossing of nave and transepts, often taking the form o lantern in several stages or levels, with a pyramidal top. England, on the other hand, a position at the west end of the n had become common during the Saxon period, as at Earl's Bar and Barnack. In the Norman period central towers became us as well as towers flanking the main entrance. Particularly p turesque were the grouped towers common in the Rhineland in the 12th century churches of Mainz and Speyer. Romanes tower design was generally simple. Shallow corner buttres were occasionally found, but the main effect was gained by

CLOCK AND OTHER TOWERS

1. The English Clock Tower in Buenos Aires. That city has many towers and monuments honouring the countries represented in its population
2. Eiffel Tower, Paris, France, built in 1889 and now used as a wireless station. It is one thousand feet in height
3. The Husainabad Clock Tower in Lucknow, India, viewed through stately palms. The Hindu tank of the original Royal Palace is near its base
4. Plaza of St. Mark, Venice, Italy, with the Cathedral and Campanile
5. The Campanile, or Giotto's Tower, at Florence, Italy
6. "Big Ben," London's most famous clock, on the Clock Tower of the Houses of Parliament
7. Tour de Beurre at Rouen Cathedral, so named because funds for its building were given in return for permission to eat butter in Lent
8. The Belfry, Bruges, Belgium
9. Tower of Westminster Cathedral
10. Martinsthor Gate at the end of the Kaiserstrasse in Freiburg-im-Breisgau, Germany
11. Ancient clock tower at Montepulciano, Italy, showing the bell and the figure which strikes the hour
12. The Siebers Tower, one of the numerous picturesque gate towers in Rothenburg, Bavaria, and one of the most interesting pieces of mediaeval architecture in the town. An old wine house is shown at the right of the tower

succession of storeys of arcaded windows; arcaded cornices or corbelled (bracketed) cornices were much used. Interesting examples of Romanesque towers are: S. Front, Périgueux; Loches; S. Pierre, Vienne; S. Paul, Issoire; the cathedral at Le Puy en Velay; and S. Germain des Prés, Paris, all of the 12th century, in France. In England, the west towers of Durham cathedral (lower part 1128, upper part 1220); the central tower at Tewkesbury (*c.* 1125) and the 12th century church at Castor are noteworthy.

The Gothic period produced profound changes in tower design. Windows and arcades were much lengthened; buttresses increased in size and complexity; corner buttresses were much emphasized and frequently crowned with pinnacles and offsets were arranged to vary the silhouette. Although many Gothic towers were designed to carry spires a large number have flat roofs with rich battlemented or traceried parapets and many pinnacles and finials. Sometimes octagonal turrets rose continuously from the ground to the top at one or more corners of the tower. The number of towers contemplated for great churches increased with their complexity. Thus in Rheims, seven towers with crocketed spires were originally planned, and at Chartres, eight; Tournai cathedral (the only scheme of the three completed) in Belgium has seven. Of flat topped towers the Tour S. Jacques, Paris (1508–1522) is a graceful example. The most beautiful of English Gothic towers are Canterbury cathedral (central tower 1495); Lincoln (western towers *c.* 1250, completed *c.* 1400), central tower (lower portion 1240–50, upper portion 1307–1311); Gloucester (central tower middle 15th century); and York (central tower 1400–1423, south-west tower begun 1432, north-west tower finished 1474) Of the smaller towers, those of Wrexham church (1506) and the famous Magdalen tower at Oxford (1492–1505) are both beautiful examples of Perpendicular richness.

Secular.—Towers are not limited to either military or religious uses Many were built in connection with town halls, others to carry clocks. Isolated belfrys are also found as at Amiens (present building 1748, on a mediaeval base), and Darnétal (1512–14); and those containing clocks at Evreux (1490); Rouen (1389, altered 1527); Bordeaux (13th and 15th centuries). The greater number of the hôtels de ville of France, Germany and the Netherlands had towers, serving as belfrys. Examples exist at S. Antonin, France (12th century), Ypres (early 14th century, now, 1928, destroyed) and Arras in Belgium (1554), while the fantastic tower of the Rathaus at Rothenburg (13th century) is characteristic of the German examples.

Oriental.—The Muslim architects rank with the greatest mediaeval tower designers, but except for a few examples in palaces, such as the 14th century Comares tower in the Alhambra at Granada, Spain, the greater number were purely religious and served for places from which the call to prayer was given The greatest of them all is the Giralda tower at Seville, originally a mosque minaret (1195), but in its present form it is crowned with a Renaissance top, built in the 17th century by the architect Hernan Ruiz. The Kutub Minar at Delhi, (early 13th century) is the most important Indian example. (*See* MINARET.)

Tower-like structures play an important part in the Brahmin temples of India and in other religious architecture of the Far East. Thus many of the temples are entered through gateways under enormous piles of masonry which take the form of oblong pyramids, lavishly covered with tier on tier of sculptured figures, carved mouldings, little projecting shrines and the like. Characteristic examples are those at Madura (17th century) and Conjeeveran. Sometimes a square, pyramidal tower is placed over the Holy of Holies of a temple, as at Madura.

In China the tower is chiefly developed as the pagoda (*q v.*), whose characteristic, repeated roofs and galleries form an interesting silhouette, typically Chinese. Japanese pagodas are similar in everything but small details.

Renaissance.—The best Renaissance towers are those of comparatively late date, for it required the imaginative freedom of the Baroque spirit to combine classic detail with the non-classic verticality a rich tower requires. Of these Baroque towers the best were those of south Germany, Austria and England, in all of which comparatively simple bases were crowned with several stages of rich, colonnaded detail, the whole topped with some sort of fantastic, curved roof. The Spanish Baroque towers differ from those already mentioned in being crowned by a lantern, usually smaller than the tower below, with frequently a low dome at the top of the entire composition; sometimes two or more stages occur, each smaller than the one below. Such towers were common, not only in Spain itself, but also in the Spanish colonies in America, existing in rich and highly developed examples in Mexico, as in the cathedral at Mexico City, and in much simplified form in the mission churches of California, as in S. Luis Rey, completed 1802.

The greater number of modern church towers follow the precedent of earlier styles, but a few of marked individuality exist. Westminster cathedral tower, London (1895–1903), by J. F. Bentley, 283 ft high, is especially interesting, also the tower of the church of Nôtre Dame at La Raincy (1924), built of reinforced concrete, by Perret Frères Other modern examples include the Eiffel tower, Paris (1889), by Gustave Eiffel, 984 ft high; in Germany, the Einstein tower, Potsdam, an observatory, (1921), by E. Mendelsohn and Stuttgart railway station (1927), by Bonatz and Scholer, in America, the Cleveland Memorial tower, Princeton university (1913), by Cram and Fergusson; the Harkness Memorial tower at Yale university (1921), by J. G Rogers; the tower of the Holder group, Princeton (1909), by Day and Klauder; and in Sweden, the tower of the city hall, Stockholm (1924), by Ragnar Ostberg. A characteristic modern use of the word tower is for high office buildings. (*See* ARCHITECTURE; INDUSTRIAL ARCHITECTURE) Office towers are also sometimes incorporated into modern governmental buildings. (*See* GOVERNMENTAL ARCHITECTURE). (T. F. H.)

TOWER OF LONDON, THE, an ancient fortress on the east side of the City of London, England, on the north bank of the river Thames. On a slight elevation now called the Tower Hill, well protected by the river and its marshes, and by woods to the north, there was a British stronghold Tradition, however, pointed to Julius Caesar as the founder of the Tower (Shakespeare, *Richard III.*, III., i. and elsewhere), and remains of Roman fortifications have been found beneath the present site. The Tower contains barracks, and is the repository of the regalia. It covers an irregular hexagonal area, and is surrounded by a ditch, formerly fed by the Thames, but now dry Gardens surround it on the north and west, and an embankment borders the river on the south. Two lines of fortifications enclose the inner bail, in which is the magnificent White Tower or Keep, flanked by four turrets. This was built by Gundulf, bishop of Rochester, *c.* 1078. Its exterior was restored by Sir Christopher Wren, but within the Norman work is little altered. Here may be seen a collection of old armour and instruments of torture, the rooms said to have been Sir Walter Raleigh's prison, and the magnificent Norman chapel of St. John. Among the surrounding buildings are the modern barracks (1845), and the chapel of St Peter ad Vincula, dating from the early part of the 12th century, but rebuilt in the early 14th and much altered in Tudor times. The Ballium Wall, the inner of the two lines of fortification, is coeval with the keep. Thirteen towers rise from it at intervals, in a chamber of one of which, the Wakefield Tower, the regalia or crown jewels (*see* JEWELS, CROWN) are kept, this room was formerly the oratory, and it is said that it was here that Henry VI. met his death (1471) while at prayers.

The chief entry to the fortress is through the Middle Tower on the west (near which was a menagerie from Norman times until 1834), across the bridge over the moat, and through the Byward Tower. On the south, giving entry from the river through St Thomas's Tower and the Bloody Tower, is the famous Traitors' Gate, by which prisoners of high rank were admitted. The chief historical interest of the Tower lies in its association with such prisoners. The Beauchamp Tower was for long the principal place of confinement for captives of rank, but dungeons and other chambers in various parts of the buildings also have similar associations; as, for instance, the Bell Tower with Queen Elizabeth when princess, Bishop Fisher, and Sir Thomas More; the Bowyer Tower

with the duke of Clarence of the butt of Malmsey legend, the Salt Tower and Broad Arrow Tower with Roman Catholic prisoners of Elizabeth's time and the Martin Tower with Colonel Blood who, in 1671, nearly succeeded in carrying off the crown and regalia, which were then kept there

Executions took place both within the Tower and on Tower Hill. Many of those executed were buried in the chapel of St. Peter ad Vincula, such as Sir Thomas More, Henry VIII's queens, Anne Boleyn and Katharine Howard, Lady Jane Grey and her husband Dudley and the duke of Monmouth The Tower was not only a prison from Norman times until the 19th century, but was a royal residence at intervals from the reign of Stephen, if not before The royal palace was demolished by order of Cromwell The tower is under the governorship of a constable The attendant staff, called Yeomen of the Guard or familiarly "Beefeaters" still wear their picturesque Tudor costume

See W Hepworth Dixon, *Her Majesty's Tower* (1869), Lord Ronald Sutherland Gower, *The Tower of London* (1901), Sir George Younghusband, *The Tower from Within* (1918), and *The Jewel House* (1920), W. G. Bell, *The Tower of London* (1921)

TOWHEE (*Papilo erythrophthalmus*), a well-known North American bird belonging to the family of the finches (*q v*) The back and breast are black, the sides chestnut, the belly white in the male, the female being brown on the back and breast The song is loud, but not over musical In the north of its range it is migratory The allied spurred towhee (*P maculatus*) breeds in the western mountains and great plains.

TOWN, in its most general sense, is a collection or aggregation of inhabited houses larger than a village The O Eng *tun* (M Eng *toun*) meant originally a fence or enclosure, *cf* Ger *zaun*, hedge, hence an enclosed place The Scottish and Northern English use of the word for a farmhouse and its buildings, a farmstead, preserves this original meaning, and is paralleled by the Icel *tun*, homestead, dwelling-house A cognate Celtic form meaning a fastness, a strong place, appears in Gael and Irish *dun*, Welsh *din*, fortress, hill-fort (*cf* Welsh *dinas*, town) This is familiar from the many Latinized names of places, *e g*, *Lugdunum*, *Augustodunum*, etc In English law "town" is not a word defined by statute For purposes of local government there are boroughs, urban districts and rural districts, but many urban districts are rural in character and the distinction is purely an administrative one (*see* BOROUGH, CITY, COMMUNE *Mediaeval*; MUNICIPIUM; ENGLAND *Local Government*, and the sections on local administration under various country headings). The meaning attached to the term "township" in the local administration of the United States is treated under UNITED STATES *Local Government*

TOWN AND CITY PLANNING. The terms town planning and city planning are used to designate the modern movement to plan the growth of cities, towns and villages, particularly in respect to the development of land for building purposes and systems of circulation When, for purposes of planning, it is necessary or desirable to deal with an area that embraces a number of adjacent communities that have separate local governments the movement is described as regional planning

Purposes.—A city grows as the result of artificial processes which need to be controlled, truly proportioned and harmonized The main purpose of planning is to mould and co-ordinate these processes in harmony with natural conditions The city, as the most dominant factor in modern civilization, calls upon the architect to recognize its fundamental relationships as a complete being and not as an aggregation of disparate building units No conception of civic design is adequate that does not envisage the city, in its ideal form, as a work of art.

Thus the general object of planning of urban areas is to influence the orderly, healthy and efficient development of communities In particular the aim of the plan should be to secure (*a*) a wholesome and reasonably spacious lay-out of the sites and surroundings of dwellings; (*b*) a well-balanced distribution of all buildings and open spaces, and of building bulks and uses of buildings in relation to street areas; (*c*) the orderly development and architectural treatment of private and public buildings; (*d*) adequate systems of streets and highways to permit free circulation of traffic, and of efficient transit and transportation services and terminal arrangements; (*e*) ample areas for all purposes of recreation and; (*f*) suitable land and water approaches The plan should deal with these and other physical improvements comprehensively, in relation to the city as a unified whole

Types.—Much of what is called town or city planning is really re-planning of towns or parts of existing towns, or the planning of portions of the undeveloped land in the environs of such towns The most prominent example of the former is Haussman's plan of Paris, and of the latter the town-planning schemes being prepared for the open areas adjacent to English towns For an effective plan for an existing city, replanning or reconstruction of defective areas should be combined with the planning of undeveloped areas On rare occasions, opportunities arise for planning and building new cities and towns from the beginning Sometimes the plans of areas forming extensions of existing cities are so elaborate and comprehensive as to be equivalent in importance to the planning of a complete town Frequent opportunities of planning *ab initio* occur for planning villages or large estates

HISTORIC TOWN AND CITY PLANNING

References to many examples of planning town settlements and some comparatively large cities exist in histories of Egypt, Mesopotamia, Greece, Rome and China Kahun (2500 B C) and Babylon have been cited as the earliest planned cities, although Aegean and Egyptian discoveries now point to a considerably more ancient date The early Italian settlements (Terremare) present traces of system in planning as far back as the Bronze age (2000 to 1800 B C) In many of the cities of the Near East, Egypt and Greece there were the same dominant characteristics pictured by Demosthenes as the combination of splendid public edifices and noble works of art with a simple and severe private life.

Later examples include Selinus and Cyrene, probably founded in the 7th century B C, as well as the Italian city of Pompeii Hippodamus of Miletus (480 B C), is referred to by Aristotle as the first architect to combine his street system with the grouping of dwellings and the treatment of the town as a harmonious whole Aristotle, however, points out that the method of Hippodamus, although advantageous aesthetically and giving the benefits of air and sun to each dwelling, was disadvantageous in time of war when the old Greek system of closely and irregularly packed houses with winding alleys and passages would be most valuable for defence He is said to have planned Peiraeus (the port of Athens), Thurii and Rhodes. Although ancient Athens was not built from a preconceived plan, the splendour of its public buildings and the accidental or deliberate axial arrangement of its few principal streets, the grouping of its buildings in relation to its streets and the comparative meanness of its residential quarters combine to express the Greek conception of civic art In the Macedonian age (330–130 B C) there was much systematic planning of town settlements and military colonies Alexandria was a prominent example of Hellenistic city planning

Vitruvius mentioned town planning and favoured the radial rather than the rectangular pattern (Schulten, *Bonner Jahrbucher*, ciii, 23) He recognized the importance of adjusting the town plan to the site, and its influence on the placing of public buildings. The surviving street plan of Turin excellently represents the Roman military system of building The Romans carried their town planning into their provinces In England the uncovered site of Silchester and the plans of ancient York and Chester show evidences of Roman work in the first century A D In Africa Timgad affords another example of the Roman systematic arrangement Zoning regulations were not unknown in Roman law; there were restrictions on the location of cemeteries and brick-fields, and on the height of tenement houses and against fire hazards, although, as in modern times, not scientifically conceived or effectively applied. The rectangular arrangement of towns practised by the Greeks and Roman military engineers continued to be followed after the fall of the Roman empire The Chinese and, later, the Mongol system of town planning was similarly rectangular

Mediaeval.—The need of defensive walls around the cities, the laying out of main streets from the entrance gates to the civic centre and the grouping of public buildings remained dominant features of town building in mediaeval times. But systematic regularity of the city street system was replaced by picturesque irregularity. The mid-European towns of the pre-Renaissance period that remain approach nearer than modern cities to being works of art. Built by artist craftsmen, cities like mediaeval Rothenburg, Nuremberg and Carcassonne are artistic units bound together by walls and decorated by towers, spires and arched

FIG 1—MAP OF WASHINGTON, D C. SHOWING PERMANENT SYSTEM OF HIGHWAYS

approaches that still survive as monuments to their builders. University towns of this period were well proportioned and openly arranged Camillo Sitte, of Vienna, in his book *Der Stadte-bau* (1889), advocated the adoption of the picturesque as opposed to the symmetrical plan, and for a time the Sitte school in Germany influenced a great deal of town extension planning

The development of architecture and the building of towns has always depended much on the leadership of statesmen and princes In one age it has been a Pericles or an Augustus, in another a Peter the Great or a Napoleon III, and in still another a Washington or a Jefferson Edward I of England was a leader in his day He directed the planning of many towns in southern France, of which Montpazier (1284), with its central market-place and arcades is an instance He laid out Flint, Carnarvon and Winchelsea in England.

Renaissance.—The picturesque irregularity of the Gothic towns with their closed pictures and many-gabled façades was supplanted in some cities in the Renaissance period by the dignified and monumental regularity of the planned city, still encircled by walls but with streets geometrically arranged within them, with wide avenues terminated on the distant vista of a palace or a castle Michelangelo was consulted on the enlargement of the Piazza della Signoria, Florence; Scamozzi prepared a design for an ideal city; and Leonardo da Vinci proposed roads on two levels. The grand manner of planning started in Italy and spread to France. Under Louis XIV. much replanning was done in Paris The planning of Versailles by Le Nôtre has had much influence on the art of planning cities Christopher Wren did similar work in England, and left to posterity one of the finest examples of town design in his plan for the rebuilding of London (1666). It should be said, however, of Sir Christopher's plan, that the requirements of the grandiose did not overshadow the truest utilitarian concern Although to London's great misfortune the plan was not carried out, much work was done in laying out squares and in building development that greatly added to the beauty of the city. Inigo Jones did much to contribute to this result. Penn's plan of Philadelphia was made in 1682, and St. Petersburg was planned in 1703 under Peter the Great. Karlsruhe and Mannheim (1715) in Germany are among the classic examples of radial and rectangular plans, respectively, and include much notable architectural work. The Government centre of Nancy designed by Emanuel Heré in 1750–57 is another notable example of town development. A beginning was made with the plan of the new part of Edinburgh in Scotland in 1767. A young architect, Craig, won the competition for laying out the new town and then followed a long period of architectural control of building construction in the Scottish capital, with which were associated such names as the brothers Adam, Playfair and Reid Splendid work was also done at this period by the Woods in Bath, by Nash in London and Grainger in Newcastle The planning of new developments in London included the reservation of many fine open squares, most of which still remain, although constantly under threat of destruction Architectural influence in these cities waned after the coming of the railroad and civic art has remained more or less in a dormant condition since. The planning of Washington, D C (1791), by L'Enfant, under the influence of President Washington and the architect-statesman Jefferson, marked an epoch in city planning

MODERN URBAN GROWTH

People congregate in towns primarily for economic reasons The growth of industrial and marketing communities begins as the result of natural advantages and concentration of transportation facilities. Most towns grow because of the means of livelihood or the cultural opportunities that they provide Certain great cities, like London and Paris, combine all features; others, like Washington, are mainly political and cultural centres The immense urban aggregations which have grown up around the harbours and railroad terminals of New York and London are unique in history and the result of a new set of forces that are encouraging a high degree of concentration In proportion as the inventiveness of man has led to the introduction of standardized methods of production, of improved methods of communication and building construction and of sanitary equipment adaptable for crowded populations, it has been possible to expand cities to great size and yet to retain a comparatively high degree of efficiency and wholesomeness In general, however, modern cities, whatever their size, suffer from lack of intelligent planning and well-balanced distribution of buildings and open spaces

Influences.—In all civilized countries urban populations have increased rapidly during the past 100 years In newer countries like the United States the urban growth has shown no signs of slackening during the present century. There are three outstanding factors in this growth, apart from its extent, which are having a great influence on the form that it is taking The first is the coming of motor vehicles and the consequent increase in the use of highways Urban growth in the 19th century was dominated by the railroad which helped to promote concentration In the 20th century the railroad continued to expand slowly, while the use of the automobile as a supplementary means of transportation has grown enormously, particularly in the United States In the United States alone, between 1905 and 1925 the number of passenger cars registered increased from 77,400 to 17,512,638, and the number of commercial trucks from 600 to 2,441,709 In America and Great Britain and on the Continent great arterial highways and fast speedways, radiating from the surrounding cities, are being constructed to provide means of circulation for this means of transport

A second influence operating in recent decades has consisted of the great expansion of rapid transit facilities City workers have thereby been enabled to live at a distance from their places of occupation, and the result has been that the most rapid urban expansion has been taking place in the environs of cities New York and London have been growing rapidly in their outskirts and actually diminishing in population in their central areas

Powerful effects on urban concentration has been caused on the Western Hemisphere by the erection of buildings of much greater heights than has been possible in the past The results of improved transit facilities, combined with the inventions of the steel frame method of building construction and the elevator, have produced the sky-scraper with possibilities of building concentration that have only been partially realized. (*See* ARCHITECTURE.) The greatest problem of a modern city is to retain

the advantages of reasonable and proper concentration in face of the tendencies for over-concentration or congestion. This congestion is due not to lack but to wrong distribution of space. The original cause of the defects in city growth is in the lack of true purpose with which the land is laid out when urban growth first takes place.

MODERN PRACTICE

Europe.—The uncertainties caused by the arrival of railroad transportation and the diversion of energy from art to mechanical engineering that accompanied the growth of manufacture prevented much general progress being made in the development of civic art in Europe during the greater part of the 19th century. Sanitation and health conditions were likewise neglected To improve these conditions public health and town extension acts embodying some planning regulations were passed in Italy, Sweden and Germany between 1864 and 1875. Under Napoleon III. of France, Haussman directed the replanning of Paris by Deschamps in 1853 and brought near to completion the remodelling of that city. The streets, places and gardens of Paris are splendidly proportioned in relation to its building heights and masses. The remodelling of central Vienna was carried out towards the end of the 19th century. At this time, Germany and Sweden were the most active countries in Europe in the development of town extension and the architectural planning of cities Before the World War extensive town planning was done in Nuremberg, Dusseldorf, Cologne, Frankfort and Hamburg. Every great Prussian and Swedish city has its town planning department, and at the present time the degree of control of new building development is probably greater in these countries than elsewhere Immediately after the World War there was much activity in town planning in the devastated regions of France. A town planning act was passed in 1919. Other post-war work included plans for Salonika and the remodelling of Athens in Greece.

Great Britain and the Dominions.—Town planning legislation was first introduced into England in 1909. The emphasis has always been on its social features. Although still limited in its application to undeveloped land, it has inaugurated new conceptions of city building that will gradually influence all forms of civic growth. Under the amended act of 1923 all urban areas having a population of 20,000 and more must prepare a plan.

The development of town planning in England has been associated with and received much of its impetus and direction from the building of garden cities (*q v*) and suburbs. Planning of large regions comprising many adjacent urban and rural districts is being carried out extensively. Many regional schemes, including the Manchester, Tyneside, Sheffield, Doncaster, Bristol, Kent, Surrey, Sussex, Essex and other city and county districts, have been prepared or are in course of preparation. A committee has been appointed to inaugurate the preparation of a plan for the whole of metropolitan London. The development of the Aldwych-Kingsway area in central London and the fine civic centre at Cardiff are two prominent examples of architectural town planning. A movement has been started to preserve the English countryside from spoilation by unregulated building development

Of modern plans for new cities two of the most important that have been prepared in recent years are for the capital cities of New Delhi in India and Canberra in Australia. (*See* also GOVERNMENTAL ARCHITECTURE.) There are town-planning laws and much activity in preparing schemes of civic improvement in Canada, Australia and New Zealand. This legislation is largely based on the British model In some Canadian provinces it is compulsory. Several Canadian cities had comprehensive plans made during 1912–14, and the improvement of the lake waterfront of Toronto was carried out on the scale of a large town-planning operation.

Orient.—In Asia, Russian and Japanese architects and engineers have done much geometrical planning An example of the former is the plan of Dalny and of the latter the work done in recent years in the replanning of Tokyo after the earthquake. Extensive plans have been made for several cities in India in addition to New Delhi, and for Manila, Singapore, Canton, Khartoum, Jerusalem and other cities in eastern countries The Straits Settlements has a town planning department attached to its government.

United States.—In the United States the harmonious and spacious grouping of monumental buildings in the Columbian Exposition in Chicago (*see* EXPOSITION ARCHITECTURE) and in the University of California, both in 1893, gave an incentive to the promotion of what was called the "city beautiful." A few years later Daniel H. Burnham, the supervisory architect of the Chicago exposition, with the aid of Edward Bennett and others, prepared the plan of Chicago (completed in 1907), whose publication, with its inspiring pictures by Jules Guerin, was a landmark in city-planning history; much of it is being gradually realized Comprehensive plans were subsequently made for San Francisco, while Cleveland, Buffalo and other cities prepared civic centre plans in quick succession. An important town-planning event in 1901 was the creation of the Senate Park Commission for the improvement of Washington with Daniel H. Burnham, Charles F McKim, Frederick Law Olmsted, Jr., and Augustus St. Gaudens as members. They reported their findings in 1902, which included the recommendation that the L'Enfant plan be adhered to, and its principles extended to new areas, and that where mistakes had been made in altering the original plan they should be corrected. The street plan of Washington has since been constantly restored to the original conception and its architectural growth has been brought up to the standard of the finest capitals of the world

In America the most popular form in which piecemeal planning is done is known as zoning (*q.v.*) In 1926, 525 communities in the United States, as against six in 1916, had prepared zoning plans, or ordinances for the purpose of controlling uses, heights and densities of buildings (*City Planning Quarterly*, April 1928) There are also 300 planning agencies at work in America, dealing with problems other than zoning. Many cities are preparing major highway or transit plans, independently of zoning or architectural features A few small towns such as Mariemount and Palos Verdes have been completely planned, and many comprehensive replanning schemes and surveys have been made. The most hopeful form in which planning is being done is in the making of regional plans for great metropolitan areas, such as New York, Washington, D.C., Philadelphia, Buffalo and the Niagara region, and Los Angeles.

The most elaborate regional survey and plan that has so far been initiated is that prepared for the New York region, which comprises 5,528 square miles Consideration was given to architectural as well as engineering, economic, social and legal problems, and groups of leading architects and landscape architects assisted in preparing designs for specific projects Their conclusions were published in May 1929 One of the chief purposes of

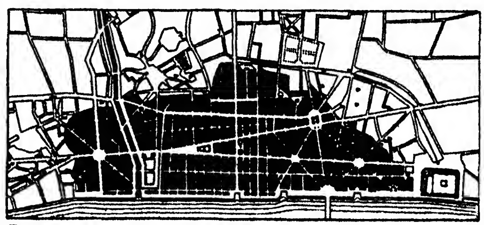

FIG. 2.—SIR CHRISTOPHER WREN'S PLAN FOR REBUILDING LONDON AFTER THE GREAT FIRE IN 1666

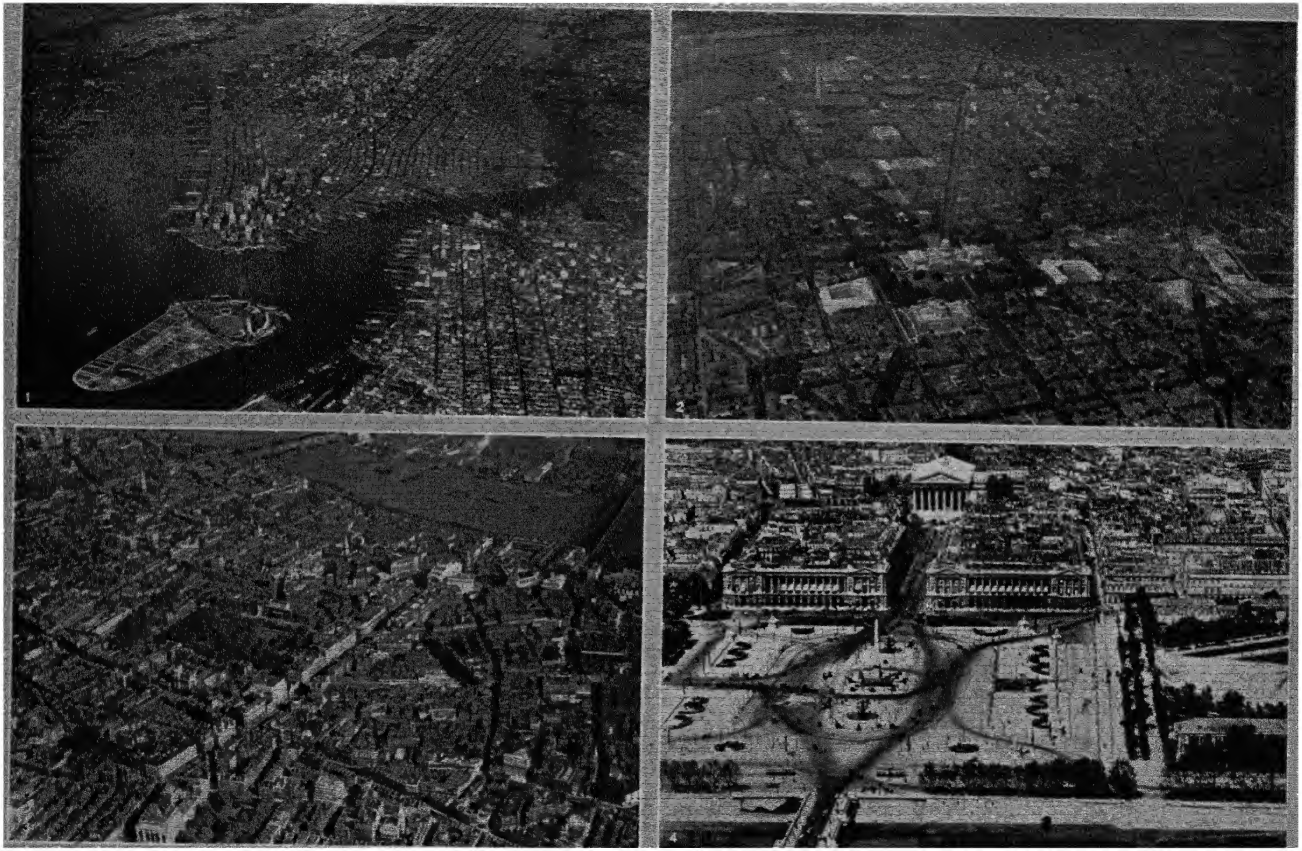
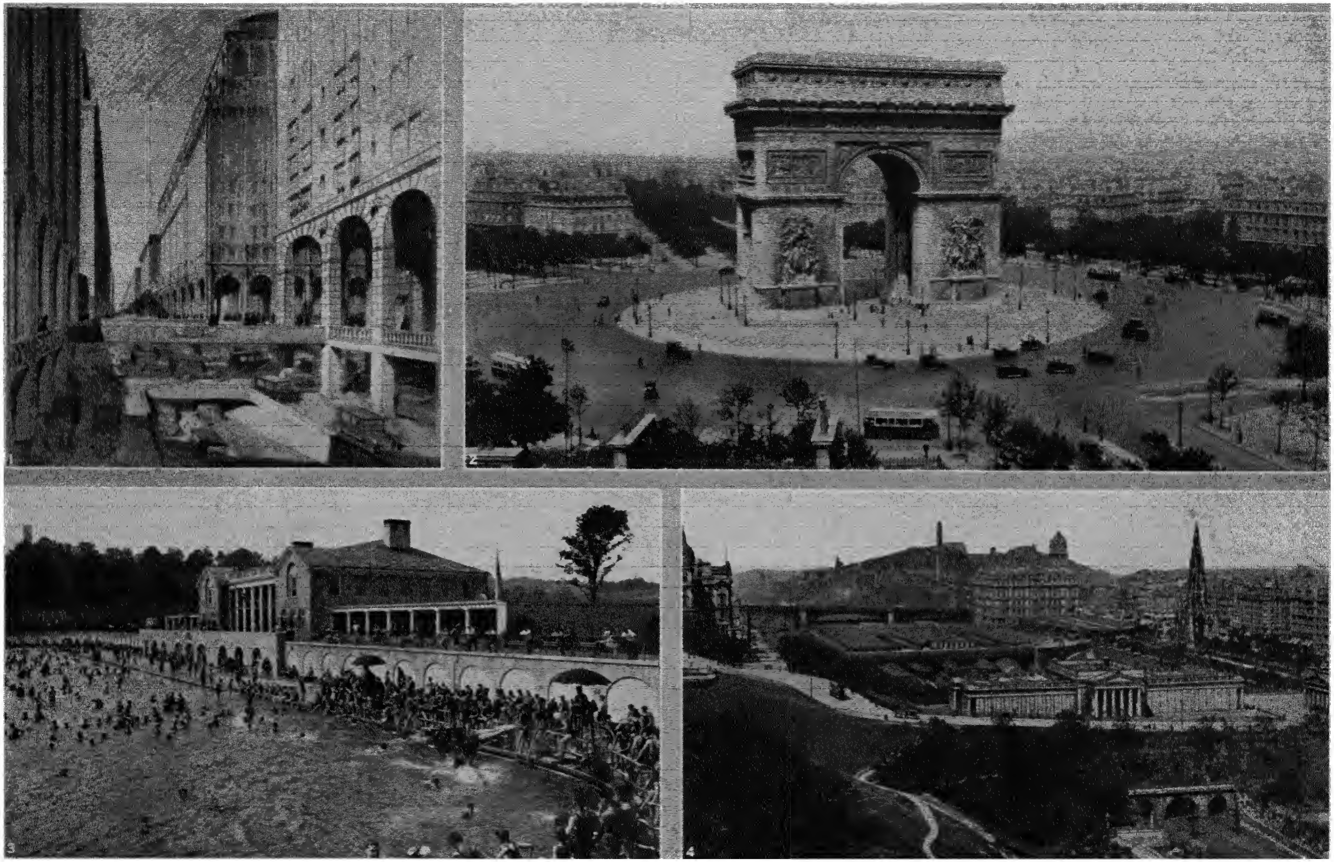
this plan is to improve the approaches to New York by water, rail and highway, and to secure a more dignified treatment of its immense waterfront.

Along with the great increase in local planning activity in the United States, the progress of the movement is indicated by the extension of State planning laws, a more favourable attitude of courts towards planning regulations, and the appointment of an advisory committee on zoning by the Department of Commerce. One of the ways in which architectural projects have been prominent in recent years has been in the improvement of railway



AEROPLANE VIEWS OF AMERICAN AND EUROPEAN CITIES

1. New York city and environs. Manhattan island, upper centre, from Battery park to beyond the north end of Central Park at 110th street. Borough of Brooklyn in right foreground, Governor's Island in immediate foreground
2. Washington, D.C. The Capitol in left centre. The Washington Monument in the upper left and Potomac River beyond
3. London, looking south to the Thames; Blackfriars bridge in upper left. Waterloo bridge in upper right. High Holborn runs diagonally from lower right corner. Kingsway runs from lower left corner. Square with trees, left centre, is Lincolns Inn Fields
4. Paris. Place de la Concorde in foreground with the Tuileries Gardens to the right. The church in the background is the Madeleine



EXAMPLES OF MODERN CITY PLANNING

1. Conjectural view showing a proposed highway plan for New York. In addition to elevated highways, this plan eliminates street intersections by having cross streets tunnelled under the avenues
2. Arc de Triomphe, Place de L'Étoile, Paris, from which radiate twelve broad boulevards
3. Architectural treatment of swimming pool and pavilion at Yonkers, N.Y., by Westchester Park System
4. Looking eastward from Castle Rock, Edinburgh, across the valley between the old town and the new. Railway submerged in right foreground; the Royal Institution which now houses the galleries of the Royal Scottish Academy is shown in the distance. The Sir Walter Scott monument can be seen at the right centre

terminals in America. New railway stations in New York, Washington, Chicago and other great centres have been built in such a way as to afford dignified entrances to these cities. (*See* INDUSTRIAL ARCHITECTURE.)

The planning and construction of parkways which was begun in Boston many years ago has now been extended to many cities. The Fairmount parkway in Philadelphia is an outstanding example of a fine central avenue linking the hub of the city with its extensive park system and including important architectural features. In the environs of New York probably the most extensive county park system in the world is being created by the Westchester park commission, and its success is largely due to the extent to which architectural design has been used for its landscape and structural features. New civic centres have been planned in many cities including Camden, Toledo, Denver and Pasadena.

MODERN TENDENCIES

The tendencies in all countries for good city planning are better to-day than they have been for the past century. The coming of the railroad destroyed interest and activity in planning cities. In recent years, electrification and improvement of steam-propelled trains, together with architectural treatment of railway stations, have been gradually destroying the convention that railway equipment and operations are essentially displeasing. The motor car has restored the highway as a principal means of travel, and the improvement of the public rights of way now absorbs the chief energies and expenditures of local governments. There is found to be need of vigilance in planning street systems, and in relating street spaces to the uses and bulks of buildings. The use of steel frame construction and of the elevator has given a new direction to building. (*See* ARCHITECTURE.) The growth of rapid transit lines is partly a cause as well as an effect of a demand on the part of the citizens for better environment in the neighbourhoods where they live Concurrent with these developments, the wealth of cities has been greatly increased and more widely distributed, and the mass of citizens has become more highly educated; consequently an increased demand for improvements in physical surroundings has been created simultaneously with a growing ability to pay for such improvements.

One of the least satisfactory features of modern town development is the disorderly growth taking place around cities that possess great architectural quality. Paris outside the ramparts, Washington outside the area planned by L'Enfant, and the modern part of Edinburgh are all suffering from lack of planning and architectural control. In the English university towns of Oxford and Cambridge the suburbs are being woefully commercialized.

The newest development in town planning in all countries arises from the need of landing places for aeroplanes. Most large cities are now developing airports, and it is important that they be attractively designed. The architectural treatment of buildings surrounding airports is of great importance too The trend of the time is towards improved living conditions and more spaciousness in city building. Unfortunately fallacies, to the effect that congestion and overcrowding are unavoidable because of lack of space, and that concentration may proceed to any limits without destroying its own advantages, still persist. Hence there are now improved standards of living, more facilities for rapid movement, better sanitation and finer buildings on the one hand, and unhealthy crowding, absence of light in buildings, congested traffic, lack of recreation spaces and uncomfortable travel on the other. The good elements in the first category give a starting point for a better conception of city building, and the very existence of the evils is, in the face of growing intelligence, a necessary stimulus to action in bringing about the realization of this conception. In the task that lies ahead, the architect, the landscape architect and the engineer must work together, for in city building, as in architecture, the best work of all three results from their cooperation.

Education.—One of the most hopeful features of the time is the development of education and research in civic problems. In several countries universities and schools now teach town planning and civic design. Although this is a development of the past 20 years, it includes not only the training of specialists in town planning, but the extension of fine art, architectural, engineering and other courses for the purposes of broadening general education. Much stimulus has been given to town planning education by the conferences and exhibitions beginning with those held in Berlin, Düsseldorf, London and Washington in 1910. Three years later a beginning was made in creating town and city-planning institutes, with architects, landscape architects, engineers and lawyers as members. Educational progress, however, has been largely in the science rather than in the actual art of town planning.

The conditions of the modern city—in size, in speed of circulation, in concentration of building masses, and in growth and standardization of industry—are unique. Whatever guidance the planner may obtain from knowledge and experience of the past, or however sound his conception of principles and traditions may be, he cannot rely upon these alone to solve the problems of the city of to-day. First hand knowledge of entirely new facts—relating to forms of aggregation and distribution of functions and of means of communication—has to be obtained. The principal contribution of the present generation of specialists in town planning seems to be that of building up knowledge of these new conditions. Most of the so-called planning that is being done is part of this process of accumulating knowledge on the basis of experiment. Considered in this light, striking progress is being made towards the time when, it is hoped, the art of building and reshaping towns will be developed on the basis of a sound scientific foundation.

TOWNSEND, SIR CHARLES VERE FERRERS (1861–1924), English general and politician, was born on Feb. 21, 1861. He first joined the Royal Marines, but in 1886 was transferred to the Indian army. He received rapid promotion, and was one of the officers in the Kashmir contingent of the Hunza-Nagar expedition of 1891 to the Himalayas, becoming military governor of Hunza. In 1895 he went with Sir G. Robertson to Chitral, on the occasion of the revolt of Umra Khan and Sher Afzil. In 1896 he returned to Egypt with Kitchener's Egyptian army, and took part in the Dongola expedition. Townsend acted for a time as military attaché in Paris, and in 1907 received a staff appointment in India. In 1909 he commanded the Orange River Colony, with the rank of brigadier-general, and two years later was promoted major-general. For a short time he held a territorial command in England, but in 1913 returned to India. The 2nd Rawal Pindi division, which he commanded at the outbreak of the World War, was stationed by the Khyber, but in April 1915 Townsend was given command of the 6th Division in

Mesopotamia. After outmanoeuvring the Turks in the flooded country round Amarah, with a fleet of barges, Townsend was encouraged to attack Kut on Sept. 26, 1915. He captured Kut, and on Nov. 22 attacked Ctesiphon, but was obliged to fall back on Kut. For a detailed account of the siege of Kut, *see* MESOPOTAMIA, OPERATIONS IN. Townsend surrendered on April 29, 1916, and was interned at Prinkipo. In Oct. 1918, the Turks released him as an emissary to make terms with the British. He received a K.C.B. for his services in Mesopotamia, but was not again employed. He resigned in 1920, and later in the same year became M.P. for the Wrekin division in Shropshire. In 1922 he joined the Conservative Party, but retired at the next election. He died on May 18, 1924.

Sir Charles Townsend published *My Campaign in Mesopotamia* (1920).

TOWNSHEND, CHARLES (1725–1767), English politician, the second son of Charles, 3rd Viscount Townshend, was born on Aug. 29, 1725, and was educated at Leiden and Oxford. At the Dutch university, he associated with Dowdeswell, his subsequent rival in politics, Wilkes, and Alexander Carlyle He represented Great Yarmouth in parliament from 1747 to 1761, when he found a seat for the treasury borough of Harwich. Townshend was a member of the Board of Trade from 1749 to 1754, and a lord of the admiralty from 1754 until his resignation in 1755 owing to his passionate attack against the ministry In 1756 he was treasurer of the chamber, and in the following spring he was summoned to the privy council.

With the accession of George III in 1760 Townshend transferred his support from Pitt to the young king's favourite, Bute, and in 1761, at the latter's instance, was promoted to the post of secretary-at-war, which he did not throw up until Dec. 1762. In the dying days of Grenville's cabinet, and throughout Rockingham's administration he held the post of paymaster-general, refusing to identify himself more closely with its fortunes as chancellor of the exchequer He accepted the latter position from Pitt in 1766, and was admitted to the inner circle of the cabinet

The defeat of his proposal to continue the land tax at four shillings in the pound, by William Dowdeswell and the landed gentry caused Lord Chatham to meditate Townshend's removal, but before this could be accomplished Chatham's mind became impaired, and Townshend, who was the most determined and influential of his colleagues, swayed the ministry as he liked, pledging himself to find a revenue in America with which to meet the deficiency caused by the reduction in the land tax. His wife was created (August, 1767) baroness of Greenwich, and his elder brother George, the 4th viscount, was made lord-lieutenant of Ireland He himself delivered in the House of Commons many speeches unrivalled in parliamentary history for wit and recklessness; and one of them still lives in history as the "champagne speech." His last official act was to carry out his intention by passing through parliament resolutions, which even his colleagues deprecated in the cabinet, for taxing several articles, such as glass, paper and tea, on their importation into America, which he estimated would produce the insignificant sum of £40,000 for the English treasury, and which shrewder observers prophesied would lead to the loss of the American colonies. Soon after this event he died somewhat suddenly on Sept. 4, 1767

The universal tribute of Townshend's colleagues allows him the possession of boundless wit and ready eloquence, marred by an unexampled lack of judgment and discretion.

A *Memoir* by Percy Fitzgerald was published in 1866.

TOWNSHEND, CHARLES TOWNSHEND, 2ND VISCOUNT (1674–1738), English statesman, was the eldest son of Viscount Townshend of Raynham (*c.* 1630–87), of an old Norfolk family descended from Sir Roger Townshend (d. 1493) of Raynham, who acted as legal adviser to the Paston family. Charles Townshend succeeded to the peerage in Dec. 1687. and was educated at Eton and King's college, Cambridge At first a Tory, when he took his seat in the House of Lords, he afterwards went over to the Whigs. In Nov. 1708 he was appointed captain of the yeomen of the guard, having in the previous year been summoned to the privy council. As ambassador extraordinary and plenipotentiary to the states-general (1709–11) he took part in the negotiations preceding the Treaty of Utrecht. In Sept. 1714, George I. selected him as secretary of State for the northern department. Townshend's policy, after the suppression of the Jacobite rising in 1715, was one of peace at home and abroad; he promoted defensive alliances with the emperor and with France. But in 1716 he was dismissed from his position owing to the intrigues of Sunderland, who persuaded George and Townshend's colleague, Stanhope, that Townshend and Walpole were plotting to place the prince of Wales on the throne.

Early in 1720 a partial reconciliation took place between the parties of Stanhope and Townshend, who was president of the council from June, 1720 until Feb. 1721, when, after the death of Stanhope and the forced retirement of Sunderland, a result of the South Sea bubble, he was again appointed secretary of State for the northern department, with Walpole as first lord of the treasury and chancellor of the exchequer. The two remained in power during the remainder of the reign of George I. (*See* ENGLAND. *History.*) Townshend secured the dismissal of his rival, John Carteret, afterwards Earl Granville, but soon differences arose between himself and Walpole. Although disliking him, George II retained him in office, but the predominance in the ministry passed gradually from him to Walpole Failing, owing to Walpole's interference, in his efforts to procure the dismissal of a colleague and his replacement by a personal friend, Townshend retired on May 15, 1730. His remaining years were passed at Raynham, where he interested himself in agriculture. He died at Raynham on June 21, 1738.

Townshend was twice married—first to Elizabeth (d. 1711), daughter of Thomas Pelham, 1st Baron Pelham of Laughton, and to Dorothy (d. 1726), sister of Sir Robert Walpole.

TOWNSHIP, a subdivision of local government, found in most of the central and western United States It is an outgrowth of New England towns and of New York and Pennsylvania local government, which was influenced both by the New England town and the Southern county. At first townships were often called towns, showing the influence of the terms of New England. Townships are generally about 6 sq m. in size, depending upon State constitutional or statutory provision The township meeting has fallen very much into disuse, just as the town meeting has ceased to be a potent factor in many parts of New England. In some of the States the chief administrative authority of the township is the committee or board, while in the others it is the supervisor, who also serves as the member of the township on the county board of supervisors. Other township officers are the clerk, assessor, treasurer, overseer of the poor and constable. Usually officials are chosen by the voters of the township

See H. G. James, *Local Government in the United States* (1921). (S. LE)

TOWNSVILLE, a port of Queensland, Australia, situated on the west side of Cleveland Bay in the north-east of the State and 750 miles north of Brisbane. It is built upon the banks and near the mouth of Ross Creek—here spanned by an iron bridge—and rises picturesquely up the lower slopes of Castle Hill which towers, a great rock-mass 936 ft. high, behind it It is the outlet for a wide area of country of varied economic potentialities The thriving town (pop. 30,000) is built substantially and, on the whole, suitably to the climate. The estuary of Ross Creek has been straightened and deepened to allow of sea-going vessels (24 ft. draught) to berth alongside the quays, and Townsville, with a total "overseas" trade valued (1926/7) at £1,550,000, is the second port of Queensland and may be termed "the capital of the North," as Rockhampton is of the centre, and Brisbane of the whole, and of southern Queensland in particular The harbour is served by a series of regular overseas shipping lines (total tonnage 1926–27: *c.* 80,000) as well as the regular coast services (combined tonnage of all classes 1926–27, 1,050,500 tons).

TOWTON, a village of Yorkshire, England, 2½m S. of Tadcaster, the scene of a battle fought on Palm Sunday, March 29, 1461, between the armies of York and Lancaster. The party of Lancaster had lately won the battle of St. Albans, but, unable

to gain admission into London, and threatened by the approach of Edward the young duke of York from the west of England, was compelled to fall back northward. York having been proclaimed as Edward IV, followed them up into Yorkshire, and on the 27th his leading troops surprised the passage of the Aire at Ferrybridge. The Lancastrians were encamped at Towton, some miles away, covering Tadcaster and York; but a force under Lord Clifford was promptly sent out, recaptured Ferrybridge by surprise, and cut to pieces the Yorkist garrison. About the same time, however, Edward's van, under Lord Fauconberg, an experienced soldier, crossed the Aire higher up, and Clifford was compelled to retire. He was closely pressed, and at Dintingdale, within a few furlongs of his own camps, was cut off and killed with nearly all his men. Edward's main body was now close at hand, and the Lancastrians drew up on their chosen battlefield early on the 29th. This field was an elevated plateau, with steep slopes, between the present Great North Road and the river Cock, cut in two by a depression called Towton Dale. On opposite sides of this depression stood the two armies, that of York facing north, their opponents southward. Both lines of battle were very dense. On a front of little more than a thousand yards the Lancastrian party had nearly 60,000 men Edward's force (less than 50,000) was not all present, the rear "battle" under Norfolk being still distant Snow and sleet blew in the faces of the Lancastrians and covered the field of battle. The skilful Fauconberg used this advantage to the utmost Aided by the wind, his archers discharged flights of arrows against the enemy, who replied blindly and feebly, hampered by snow and wind. The Yorkists withdrew until the enemy had exhausted their quivers, and then advanced afresh. Their arrows soon stung the Lancastrians into a wild and disorderly charge Suffering severe losses the latter closed with Edward's line of battle No quarter was given by either party, and on the narrow front the numerical superiority of the Lancastrians counted for little The long, doubtful and sanguinary struggle was only decided by the arrival of Norfolk's corps, which charged the enemy in flank. Driven backwards and inwards, the Lancastrians were in a desperate position, for their only way of escape to Tadcaster crossed the swollen waters of the Cock by a single narrow and difficult ford, and when, after a stubborn struggle, they finally broke and fled, they were slaughtered in thousands as they tried to cross At the close of the day the defeated army had ceased to exist 25,000 Lancastrian and 8,000 Yorkist dead were buried in and about Towton.

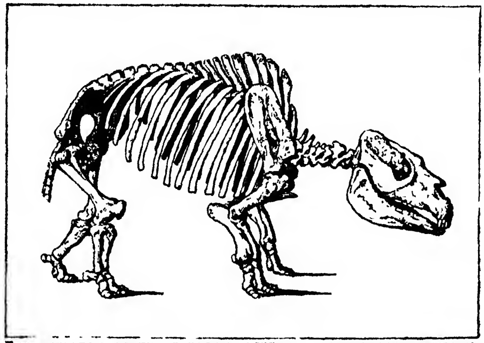
See R. Brooke, *Visits to English Battlefields* (London, 1857); C R. B. Barrett, *Battles and Battlefields of England* (London, 1896), H. B. George, *Battles of English History* (London, 1895).

TOXICOLOGY, the name of that branch of science which deals with poisons, their effects and antidotes, etc. (*See* POISONS and MEDICAL JURISPRUDENCE)

TOXIN: *see* DIPHTHERIA, SCARLET FEVER, MEDICAL RESEARCH.

TOXODONTIA. An extinct order or sub-order of South American hoofed mammals, some (toxodonts) being massively-proportioned three-toed beasts which played the part of rhinoceroses, and others (typotheres) small animals more nearly comparable to rabbits and the larger rodents in appearance and probably in habits. The order was distinguished by long-crowned, often rootless teeth of peculiar pattern, the front teeth enlarged and somewhat like those of rodents, the cheek teeth of triangular pattern above and unequal crescents below, the jaws deep and rather short, heavy zygomatic arches and the mastoid bone peculiarly inflated. The feet have from three to five digits, the arrangement of the carpals is alternating but the astragalus has a short neck and convex head, the fibula articulates with the calcaneum but the navicular does not reach the cuboid. In the Miocene of Patagonia the toxodonts are of moderate size, *Nesodon* as large as a tapir, *Adinotherium* of the size of a sheep, and the typotheres are all small creatures comparable with a wood-chuck or guinea-pig. In the Pleistocene of Argentina *Toxodon* equals the Indian rhinoceros in size, *Toxodontherium* and *Xotodon* of the Pliocene are no less gigantic, while *Typotherium*, the largest of the smaller group, may be compared to the modern capybara.

A third assemblage, the Entelonychia, is related to the toxodonts and typotheres and included with them under the order Notoungulata (also called Toxodonta). They are more primitive in teeth and foot-construction, many of them brachyodont, five toed, clawed and chiefly found in the older Tertiary formations of South America, with a few specialized survivors in the Miocene Among these last *Homalodontotherium*, with large compressed claws but with grinding teeth somewhat like the rhinoceros type, is analogous to the Chalicotheriidae of the northern world, while



THE SKELETON OF THE TOXODON, AFTER A CAST IN THE AMERICAN MUSEUM OF NATURAL HISTORY

Astrapotherium shows a remarkably close parallelism to the *Metamynodon* of the north The Litopterna (*q v*) also have some affinity to the notoungulate groups, the whole assemblage being peculiar to South America save for a couple of small and primitive entelonychians found in the Lower Eocene of Wyoming (*Arctostylops*) and the Paleocene of Mongolia (*Palaeostylops*); these may indicate that these South American Tertiary "ungulates" originally came from Holarctica about the end of the Cretaceous

The invasion of South America by northern mammal faunas at the end of the Tertiary period brought about the progressive extinction of the toxodonts and their allies, *Toxodon* and *Macrauchenia* being the last survivors Unlike the edentates, the South American hoofed animals do not seem to have made any counter-invasion into North America. (W D. M)

TOY, CRAWFORD HOWELL (1836–1919), American Hebrew scholar, was born in Norfolk, Va, on March 23, 1836 He graduated at the University of Virginia in 1856, completed in one year the three-year course at the Southern Baptist theological seminary, served in the Confederate army, studied at the University of Berlin in 1866–68 and taught in various southern educational institutions His resignation from the seminary in which he had studied was accepted in 1879 because of his sympathy with Darwin's views on evolution and his belief that in spite of their divine inspiration there were obvious human errors in the Scriptures which, however, concerned the shell, not the kernel, of religious truth. After a brief period with the *Independent* he went to Harvard as professor of Hebrew and Oriental languages and until 1903 Dexter lecturer on biblical literature. He became professor emeritus in 1909 and died in Cambridge, May 12, 1919 He was the author of *History of the Religion of Israel* (1882), *Quotations from the Old Testament in the New Testament* (1884), *Judaism and Christianity* (1890), *Introduction to the History of Religions* (1913) and of various critical and exegetical works

See sketches in the *American Journal of Semitic Languages and Literature* (vol. xxxvi., Oct. 1919) and the *Harvard Theological Review* (vol. xiii., Jan. 1920).

TOY, a child's plaything; also a trifle, a worthless, petty ornament, a gew-gaw, a bauble. Children's toys and playthings survive from the most remote periods, though many so-called diminutive objects made and used by primitive man, sometimes classified as playthings, may have been workmen's models, votive offerings or sepulchral objects. A large number of wooden, earthenware, stone or metal dolls remain with which the children of

ancient Egypt once played; thus in the British Museum collection there is a flat painted wooden doll with strings of mud-beads representing the hair, a bronze woman doll bearing a pot on her head, an earthenware doll carrying and nursing a child; some have movable jointed arms There are also many toy animals, such as a painted wooden calf, a porcelain elephant with a rider; this once had movable legs, which have disappeared. Balls are found made of leather stuffed with hair, chopped straw and other material, and also of blue porcelain or papyrus. Jointed dolls, moved by strings, were evidently favourite playthings of the Greek and Roman children, and small models of furniture, chairs, tables, sets of jugs painted with scenes of children's life survive from both Greek and Roman times. Balls, tops, rattles and the implements of numerous games, still favourites in all countries and every age, remain to show how little the amusements of children have changed. (*See* also DOLL; TOP)

TOYNBEE, ARNOLD (1852–1883), English social reformer and economist, second son of Joseph Toynbee (1815–1866), a distinguished surgeon, was born in London on Aug. 23, 1852 He had originally intended to enter the army, but ill health and a growing love of books changed his plans, and he settled down to read for the bar. Here again the same causes produced a change of purpose, and he entered as a student at Pembroke College, Oxford Two years later he removed to Balliol college, where, after taking his degree, he was appointed lecturer and tutor to students preparing for the Indian civil service. He devoted himself to the study of economics and economic history. He was a practical social reformer, taking part in much public work and delivering lectures in the large industrial centres on economic problems. He overtaxed his strength, and after lecturing in London in January 1883 he had a complete break-down, and died of inflammation of the brain at Wimbledon on March 9.

Toynbee had a striking influence on his contemporaries, not merely through his intellectual powers, but by his strength of character, love of truth and ardent and active zeal for the public good. He was the author of some fragmentary pieces, published under the title of *The Industrial Revolution* (1884).

Toynbee's interest in the poor and his anxiety to be personally acquainted with them led to his close association with the district of Whitechapel in London, where Canon Barnett (*q.v.*) was at that time vicar—an association which was commemorated after his death by the social settlement of Toynbee Hall, the first of many institutions for social betterment. (*See* SETTLEMENTS.)

See F. C. Montague's *Arnold Toynbee* (Johns Hopkins University Studies, 1889); Lord Milner's *Arnold Toynbee: a Reminiscence* (1901); and L. L. Price's *Short History of Political Economy in England* for a criticism of Toynbee as an economist; also a new edition of his *Lectures on the Industrial Revolution* (1919), with preface by Lord Milner.

TOYNBEE, PAGET (1855–), English philologist and critic, was born at Wimbledon on Jan. 20, 1855, and educated at Haileybury and at Balliol college, Oxford. From 1878 he acted for 14 years as private tutor, afterwards making a name for himself as a Dante scholar. He has also published and edited a number of works relating to Horace Walpole.

His publications include *Specimens of Old French, with Notes and Glossary* (1892); *Life of Dante* (1900; 4th enlarged ed., 1910); *Dante Studies and Researches* (1902); *Chronological List of English Translations from Dante, from Chaucer to the Present Day* (1906); *Dante in English Literature from Chaucer to Cary* (2 vols., 1909); *Critical Texts of Letters of Dante* (1915–19, amended text and translation, 1920); *Dante Studies* (1921); *Horace Walpole's Journal of the Printing Office at Strawberry Hill* (1923); *Horace Walpole's Reminiscences* (1924), etc.

TOYNBEE HALL. Founded in London by Canon Barnett, then rector of St. Jude's Whitechapel in 1884, and named after Arnold Toynbee, a brilliant economist and co-worker whose death shortly before had been hastened by his zeal for social reform, Toynbee Hall, the pioneer university settlement, inaugurated an important movement (*see* SOCIAL SETTLEMENTS). In the earlier years of his ministrations at St. Jude's, Barnett had succeeded in creating interest at Oxford and Cambridge in the problems of East London and had brought to Whitechapel a considerable number of undergraduates to spend their holidays with him and learn about social conditions. The connection which was established in this way prepared the universities for the suggestion of a closer union between them and the East End and Barnett's plan to found a settlement: that is, a house of residence for university undergraduates who might wish to live in an industrial area, was at once warmly supported. With money collected mainly at Oxford he was able to purchase and reconstruct premises next door to St. Jude's which had been used for the purposes of an industrial school and with the help of a band of "settlers" to commence activities which left an enduring mark on the social history of the period. Mainly these activities were concerned with the collection of social data, with social experimentation, and with the amelioration of social and industrial conditions; but Barnett's underlying aim was to bring the generosity and learning of the young and the universities into effective relation with the industrial population so that both communities might come in time to serve ideals of citizenship and neighbourliness.

The War involved the closing of the hostels (Balliol house and Wadham house) which Barnett had founded for working men students at Toynbee Hall and in other ways suspended the operations of the settlement. Since 1919 however most of its customary activities have been resumed and its work as a "popular university" has been extended. An important feature of its annual programme is now a large "American Summer School" which is attended by about 100 preachers, educationalists and social workers from the United States, selected because of their interest in the international aspect of social and economic problems.

(J. J. M.)

TOZZI, FEDERIGO (1883–1920), Italian novelist, was born at Siena on Jan. 1, 1883, the son of an innkeeper. His childhood and early youth are described in *Con gli ochi chiusi* (1919). His father died in 1908, and Tozzi married the same year, and *Il Podere* (1921) is a record of his experiences at this time. He learnt Latin and studied old Tuscan, his first book being an *Antologia d'antichi scrittori senesi* (1913). *Tre Croci* (1920) translated into English as *Three Crosses* (1921), the only one of his novels which is not autobiographical, is considered his finest work. He died in Rome on March 21, 1920, before he was able to reap the fame which the success of his latest work brought him.

TRACERY, the term given in architecture to the upright curving or intersecting bars or ribs, used in a window or other opening to give beauty and variety to its silhouette. The term is also applied to similar forms used in relief, as wall decoration (sometimes called wall-tracery), and hence, figuratively, of any intricate line pattern. The word is often restricted to the elaborate system of window decoration, with its derivative forms, developed in Europe during the Gothic period, but it may, with equal validity, be applied to the pierced marble screens common in the Mogul work of India, or to the pierced plaster windows of Persia, Turkey, Syria and Egypt.

The origin of European tracery is confused. Pierced marble screens, with the openings glazed, were used occasionally in Byzantine work. The Byzantines also used, commonly, groups of two, three or even more narrow, arched windows, placed close together, under a single, large, relieving arch above. In this they were followed by most of the Romanesque styles. In such groups, the supports between the adjacent openings of each group usually consisted of single colonnettes, hence the arches over them were thin and shallow; and the tympanum, or section of wall supported by them and filling the space between them and the great enclosing or relieving arch over the whole group, was necessarily thin also. Such windows are found in the greater number of Italian campaniles and Romanesque towers, as well as in many Romanesque triforium arcades. To decorate the tympanum, piercing was an obvious and simple method. The result was the germ of tracery.

Plate Tracery is found in early Gothic work both in France and England. In its simplest forms the tympanum is pierced with a single opening, usually circular, but occasionally taking a four-lobed or quatrefoil form. The points between the lobes, known as cusps (*q.v.*), later became an important element in

EXAMPLES OF TRACERY

1. Geometric decorated English Gothic tracery; Angel Choir, Lincoln Cathedral, 1250–80. 2. Mogul pierced marble tracery; screen in the Taj Mahal, Agra, India, 1632. 3. Rayonnant French Gothic tracery; transept rose window, Notre Dame Cathedral, Paris, *c.* 1270. 4. Rayonnant French Gothic tracery; rose window from St. Nazaire, Carcassonne, France, beginning of the 14th century. 5. Perpendicular English Gothic tracery; west front, St. George's Chapel, Windsor, begun 1474. 6. Early Perpendicular English Gothic tracery; east window, York Cathedral, 1408. 7. Curvilinear Decorated English Gothic tracery; west front, York Cathedral, 1338

much Gothic ornament. In time, greater elaboration was sought by increasing the number and complexity of the piercings, and thus both the size and beauty of the entire unit. The climax of plate tracery appears in France in the group of magnificent windows of Chartres cathedral (1194–1212); and in England in the rose window at Lincoln cathedral (1220), known as the Dean's eye.

Bar Tracery.—As skill in stone cutting and desire for complexity increased, the area of the tympanum wall left solid grew continually smaller, finally leaving only thin bars of stone separating the adjacent openings. Moreover, in Notre Dame cathedral, Paris, certain small, interior, round windows constituting a sort of upper triforium in the original design, carried decorations of little inverted arches built of stone—a sort of rudimentary tracery. About 1220 the next inevitable step in the development was taken, and a window was considered not as a group of lights carrying a little piece of pierced tympanum wall, but as a group of lights where arches are formed of a bar of stone similar in section to that of the mullion or support between them, with the space between these arches and the enclosing arch—the old tympanum—occupied by a pattern of similar stone bars. In early work this pattern usually consists of a circle, sometimes cusped, tangent both to the enclosing arch and to the small arches of the lights below it. The cusps are usually of the type known as "soffit cusping," cut on separate pieces of stone set into grooves in the inner faces of the circle.

French Rayonnant Tracery.—In France, bar tracery occurs in the rebuilt clerestorey of Notre Dame (between 1220 and 1230) in its simplest possible form, and in a more developed type, with cusps, in the apse chapels of Reims cathedral (prior to 1230). From about 1240 on it becomes common, rapidly increasing in lightness and complexity In general, the pattern types are restricted. There are two, three or four lights. In two-light windows, a single cusped circle is the crowning feature. In three-light windows, three smaller cusped circles fill the space above. Four-light windows are formed of two two-light windows, with an additional cusped circle above. In France the spring of the arches of the lower lights is kept far below that of the enclosing arch, so that the crowning circle is large. During the late 13th century, curved-sided triangles, and trefoil and quatrefoil forms, without enclosing circles, are occasionally used. In four-light windows, the central mullion is often made heavier than the side mullions, both in depth and width, and this additional size carried around the enclosing arches of the side pairs. This heavier bar will have a section or profile, part of which is a duplicate of the smaller bars' mullions. Thus tracery of two planes and two moulding types is developed—one, that of the smaller bars, and the other, that of the larger. Each moulding type plane is known as an "order," and such a window is said to have tracery of two orders. The climax of French Rayonnant tracery can be seen in S. Urbain at Troyes (1270), S. Chapelle in Paris (1246–48) and S. Nazaire at Carcassonne (early 14th century). The rose windows (*q.v.*) of the style, such as those of Notre Dame at Paris (*c.* 1270), decorated with radiating patterns using similar combinations of forms—arches, circles, cuspings, etc.—are perhaps the most remarkable traceried windows of the style. During the later Rayonnant period, tracery forms came to be used decoratively, for wall surfaces, pinnacles, gables, etc. Especially noteworthy is the filling of gables of porches, above the door arches, with tracery forms. At first this was done simply, with little piercing; later, as in the Portail des Libraires, at Rouen cathedral (*c.* 1280), the gable became a mere decorative screen of lace-like open tracery. French Rayonnant tracery was the controlling influence in all continental tracery outside Italy.

English Geometric Tracery.—Based on the same simple arch, circle and cusp forms as the French tracery, the English geometric tracery is infinitely richer and more varied. The great east end and west windows of the cathedrals allowed the development of four-, six- or eight-light windows, designed in two or three orders, carefully systematized, like the east window of Lincoln cathedral (*c.* 1280), in eight lights, with three orders. But the greatest change is in single order windows of smaller size. In these the use of cusps without circles became common, and all sorts of star-shaped, triangular and other geometric forms occur.

English Curvilinear Tracery.—In the early years of the 14th century the English architects discovered that by the use of the ogee (*q.v.*) curve, or curve of double curvature, the occasional harsh angularities of the geometric style could be avoided, and wavy-lined tracery of great beauty produced. This gave rise to the so-called curvilinear tracery. Its simplest form is the reticulated, or network window in which the entire upper part is filled with a regular all-over pattern of waving bars, rhythmically tangent and then separating. But the introduction of the reverse curve set free the imagination of the designer, and an infinite number of varying types resulted, such as the rose window at Lincoln cathedral (1350), or the great west window at York (*c.* 1338).

Perpendicular Tracery.—By the end of the 3rd quarter of the 14th century a reaction had set in against this flowing curvature, and the 15th century saw the new style—the so-called perpendicular—triumphant. It was based on one controlling idea—verticality. Mullions were run through unbroken from bottom to top. At intervals they were connected by horizontal bars running across the window, supported on little arches between the mullions, thus dividing the whole window into tiers of little arch-headed lights. At the top there is great variety of treatment, but almost always the upper lights are smaller than those below; and there was frequent use of curved bars intersecting the verticals, and to some extent recalling the arched forms of the earlier styles. This new feeling appears in the transept window of Gloucester cathedral as early as 1335, and in a more developed form in the east window of the choir, which fills the entire east end, about 1350. During the 15th century the lines become more and more rectangular and the window heads have flatter and flatter arches. The climax of this development is reached in such enormous end windows as those of the King's College chapel, Cambridge, and St. George's chapel, Windsor (*c.* 1525).

Wall tracery of perpendicular character was widely used both for exterior and interior work during the 15th and early 16th centuries. Great areas are sometimes filled with tiers of traceried panels, as in the Henry VII. chapel, Westminster Abbey (begun 1502). In some cases, where flint was common, a tracery of cut stone, filled in with dark flints, decorates church exteriors, as in Long Melford church and St. Laurence at Ipswich. Traceried forms are also the basis of much screen, stall and tomb design of the 15th century; rood screens are particularly rich. Tracery is also the basis of the decorative rib treatments of fan vaulting (*See* FAN VAULT; VAULT.)

French Flamboyant Tracery.—In the last years of the 14th century the reverse curve came into use in French tracery, probably as the direct result of English curvilinear models. The French, however, soon gave tracery of this kind an individual spirit. In the best Flamboyant work, such as the tracery of S Maclou, Rouen (begun 1432), and the west front of Rouen cathedral (begun 1481), all of the forms are slimmer and more flame-like than is usual in English work. Particularly interesting is the application of Flamboyant tracery to rose windows, like that of the south transept of Beauvais cathedral (1500–48), in which the radiating character of the earlier types is maintained, although combined with the reverse curve. Flamboyant tracery forms the chief decoration of many gorgeous choir stalls and screens. The screen at Albi (*c.* 1500) has tracery of unbelievable lace-like delicacy in its canopies, as well as larger patterns covering wall surfaces; the wood choir stalls of Amiens (1508–19) are even more delicate and the tracery is of the utmost richness and intricacy. Noteworthy, also, is the application of Flamboyant tracery forms to exterior detail, as in the porch of S. Maclou, Rouen, and the west front of S. Wulfran at Abbeville (1480).

Italian Tracery.—Due to the Italian lack of understanding of Gothic structural principles, tracery never achieved in Italy the logical development of the north. The nearest approach to this is in the bands of tracery of Venetian palace windows, such as those of the Ca d'Oro (1430), by G. and B. Bon. Elsewhere, tracery was only understood as beautiful pattern, and much of it,

even when copying the forms of bar tracery, is pierced from large sheets of marble, as in the triforium of the cathedral at Lucca (*c.* 1400) and the cloister of S. Maria della Verita, at Viterbo.

Tracery in the Orient.—The Mohammedan designers not only followed Byzantine precedent in using pierced marble screens for windows but also, by the development of a new technique, invented a characteristic type of tracery, which combined the functions played by both leading and stone tracery in western work. This technique consisted in filling the window area with a pierced sheet of cement, each piercing being filled with a piece of coloured glass. Results of jewel-like intensity and brilliance were thus obtained, and being made of a plastic material, tracery of this type could have unlimited variety of pattern The usual types found were basically floral, with the leaf shapes in glass, carefully arranged to give a sense of flow and growth. Such cement tracery is found particularly in the later work of Cairo, such as the mosque of Barkouk (*c.* 1384) and in the imperial Turkish work, such as the brilliantly jewelled windows in the 17th century mosque of Suleiman, Constantinople In India, where ventilation is required, rather than floods of light, a different type was developed, without glass, and in a richer material—carved and pierced marble Thus, in almost all of the great Mogul palaces, and in many of the tombs, large, pointed arch openings are filled with sheets of white marble, pierced in the most elaborate patterns, of the finest scale. The most delicate example of this pierced, marble tracery is that of the screen around the sarcophagi in the Taj Mahal (*q v.*), at Agra (1632–47).

Modern Types.—Church architects of the 20th century, working, frequently, in a modernized Gothic style, have found in tracery a congenial means of free expression Both geometric and curvilinear forms have furnished inspiration, but patterns have been developed of a freshness and individuality frequently quite different from the mediaeval custom In these, foliated ornament is frequently added to the tracery basis. Noteworthy examples occur in Liverpool cathedral (Sir G G Scott, architect, still, 1928, uncompleted) and in the west front of the church of the Heavenly Rest and the Beloved Disciple, New York (1928), by Mayers, Brust and Philip, the Goodhue associates An entirely modern development is seen in the use of pre-cast cement tiles, pierced in geometric patterns and glazed, built up into large windows, as in the church of Notre Dame at Raincy, France (1924) by Perret Frères (*See* GOTHIC ARCHITECTURE; INDIAN ARCHITECTURE) (T F H)

TRACHEA, in zoology (1) the windpipe of air-breathing vertebrates, extending from the pharynx towards the lung It ultimately bifurcates into two bronchi, one to each lung The larynx, or voice-box, is a modified part of the trachea (2) The breathing tubes of insects (*q.v.*). The ramifications of the insect tracheae are called *tracheoles*

TRACHELIUM, in architecture the neck of the capital of the Doric and Ionic orders. In the Greek Doric capital it is the space between the annulets of the echinus and the grooves which marked the junction of the shaft and capital In the Roman Doric and the Ionic orders the term is given to the interval between the lowest moulding of the capital and the top of the astragal and fillet. (*See* also HYPOTRACHELIUM)

TRACHEOTOMY, the operation of opening the trachea or windpipe (*see* RESPIRATORY SYSTEM) and inserting a tube to provide a means of breathing when the natural air-passage is obstructed. The operation is by no means easy when performed on a small child, for the wind-pipe is deeply placed amongst important structures The chief anxiety is in connection with haemorrhage, for the vessels are large and generally overfull on account of the impairment of the respiration The higher the opening is made in the trachea the easier and safer is the operation. Formerly, it was frequently performed in diphtheria (*q.v.*) but since the introduction of diphtheria antitoxin it has rarely become necessary In adults tracheotomy is usually done for laryngeal obstruction by disease or foreign bodies

TRACHIS, a city of ancient Greece, at the head of the Malian Gulf in a small plain between the rivers Asopus and Melas, enclosed by Mt. Oeta which here descends close to the sea and at the Trachinian Cliffs commanded the main road from Thessaly The position was well adapted as an advanced post against invaders from the north, and furthermore guarded the road up the Asopus gorge into the Cephissus valley. Its citadel, Heracleia, was a subject of dispute between the Spartans and the Thebans at the end of the fifth century B.C. In Strabo's time the citadel alone was inhabited.

See Strabo p. 428; Herodotus vii. 198–203; Thucydides iii. 92, v. 51–52, Diodorus xiv. 38, 82; Livy xxxvi. 22–24. W. Leake, *Travels in Northern Greece*, iii. 24–31 (London, 1835); G. B. Grundy, *Great Persian War*, pp. 261–264 (London, 1901).

TRACHOMA, the name given to a chronic destructive inflammation of the conjunctiva (*see* EYE: *Diseases*), or "granular conjunctivitis" (Egyptian ophthalmia) It is contagious, associated with dirty conditions, and common in Egypt, Arabia and in some congested districts of south-eastern Europe Hence it has become important, in connection with alien immigration into the United Kingdom and America, and the rejection of those who are afflicted with it. It is important that all cases should be isolated, and that spread of the infection should be prevented.

TRACHYTE (Gr. τραχύς, rough), in petrology, a group of volcanic rocks which consist mainly of sanidine (or glassy orthoclase) felspar Very often they have minute irregular steam cavities which make the broken surfaces of specimens of these rocks rough and irregular; whence comes their name, which was first given by Hauy to certain rocks of this class from Auvergne, and long included quartz-trachytes (now known as liparites and rhyolites) and oligoclase-trachytes, which are now more properly assigned to andesites.

Mineral Composition.—The trachytes are often described as being the volcanic equivalents of the plutonic syenites. Their dominant mineral, sanidine felspar, very commonly occurs in two generations, *i.e.* both as large well-shaped porphyritic crystals and in smaller imperfect rods or laths forming a finely crystalline ground mass. With this there is practically always a smaller amount of plagioclase, usually oligoclase; but the potash felspar (sanidine) often contains a considerable proportion of the soda felspar, and has rather the characteristics of anorthoclase or cryptoperthite than of pure sanidine

Quartz is typically absent from the trachytes, but tridymite (which likewise consists of silica) is by no means uncommon in them It is rarely in crystals large enough to be visible without the aid of the microscope, but in thin slides it may appear as small hexagonal plates, which overlap and form dense aggregates; they often cover the surfaces of the larger felspars or line the steam cavities of the rock, where they may be mingled with amorphous opal or fibrous chalcedony. In the older trachytes secondary quartz is not rare, and probably sometimes results from the recrystallization of tridymite.

Of the ferromagnesian minerals present augite is the most common. It is usually pale green, and its small crystals are often very perfect in form. Brown hornblende and biotite occur also, and are usually surrounded by black corrosion borders composed of magnetite and pyroxene. Sometimes the replacement is complete and no hornblende or biotite is left, though the outlines of the cluster of magnetite and augite may clearly indicate from which of these minerals it was derived. Olivine is unusual, though found in some trachytes, like those of the Arso in Ischia Basic varieties of plagioclase, such as labradorite, are known also as phenocrysts in some Italian trachytes. Dark brown varieties of augite and rhombic pyroxene (hypersthene or bronzite) have been observed but are not common Apatite, zircon and magnetite are practically always present as unimportant accessory minerals.

The trachytes being very rich in potash felspar, necessarily contain considerable amounts of alkalis; in this character they approach the phonolites. Occasionally minerals of the felspathoid group, such as nepheline, sodalite and leucite, occur, and rocks of this kind are known as phonolitic trachytes. The soda-bearing amphiboles and pyroxenes so characteristic of the phonolites may also be found in some trachytes; thus aegirine or aegirine-augite forms outgrowths on diopside crystals, and riebeckite may be present in spongy growths among the felspars of the ground mass

(as in the trachyte of Berkum on the Rhine) Trachytic rocks are typically porphyritic, and some of the best-known examples, such as the trachyte of Drachenfels, show this character excellently, having large sanidine crystals of tabular form 1–2 in. in length scattered through their fine-grained ground mass

Two types of ground mass are generally recognized. the trachytic, composed mainly of long, narrow, sub-parallel rods of sanidine, and the orthophyric, consisting of small, squarish or rectangular prisms of the same mineral. Sometimes granular augite or spongy riebeckite occurs in the ground mass, but as a rule this part of the rock is highly felspathic Glassy forms of trachyte (obsidians) occur, as in Iceland, and pumiceous varieties are known (in Teneriffe and elsewhere), but as contrasted with the rhyolites, trachytes have a strong tendency to crystallize, and are rarely vitreous.

Distribution.—Trachytes are well represented among the Tertiary and Recent volcanic rocks of Europe. In Britain they occur in Skye as lava flows and as dikes or intrusions, but they are much more common on the Continent, as in the Rhine district and the Eifel, also in Auvergne, Bohemia and the Euganean Hills In the neighbourhood of Rome, Naples and the island of Ischia trachytic lavas and tuffs are of common occurrence In America trachytes are less frequent, but occur in S. Dakota (Black Hills). In Iceland, the Azores, Teneriffe and Ascension there are Recent trachytic lavas, and rocks of this kind occur also in New South Wales (Cambewarra range), East Africa, Madagascar, Aden, etc

In England there are Permian trachytes in the Exeter district, and Carboniferous trachytes in many parts of the central valley of Scotland The latter differ in no essential respect from their modern representatives in Italy and the Rhine valley, but their augite and biotite are often replaced by chlorite and other secondary products Permian trachytes occur also in Thuringia and the Saar district.

Closely allied to the trachytes are the *Keratophyres*, which occur mainly in Palaeozoic strata in the Harz (Germany), in the Southern Uplands of Scotland, in Cornwall, etc. They are usually porphyritic and fluidal; and consist mainly of alkali felspar (anorthoclase principally, but also albite and orthoclase), with a small quantity of chlorite and iron oxides Many of them are lavas, but others are probably dikes or thin intrusions. As the analyses given above will show. they differ from trachytes mainly in being richer in soda. (J S F)

TRACK AND FIELD SPORTS, a term used in the United States for those sports called *athletic sports* in England. For a full description of these athletic events in England and further description of the national athletic bodies in the United States *see* ATHLETIC SPORTS and also the separate articles on each sport The article below covers only the track and field sports in the United States. They include foot-racing upon the flat and over obstacles such as hurdles, hedges and water-jumps; jumping for distance and height either with or without the aid of pole or weights, and the propulsion through the air by the use of the arms and body of objects and weights (the weight being sometimes called a shot) for distance or height such as the discus, javelin and hammer. The first national athletic body formed in America was the Intercollegiate Association of Amateur Athletics of America. Founded in 1875 it had as its original members Amherst, Columbia, Cornell, Harvard, Princeton, Trinity, Union, Williams, Wesleyan and Yale A month later these were joined by Dartmouth, Pennsylvania, College of the City of New York, Brown and Bowdoin Forty-one colleges and universities were members in 1928. The association holds two great annual championship meetings, the May outdoor meeting, instituted in 1876, and the March indoor meeting, inaugurated in 1922. In 1917, owing to the World War, no meeting was held. At the first meet, held at Saratoga in 1876, the following events were contested· 100-yd. dash, quarter-, half-, one-, and three-mile runs, one- and three-mile walk, 120-yd hurdles, shot put, baseball throw, high jump, and long jump Ten colleges were represented by 28 individual athletes At the fifty-first annual track and field championship meeting, held at Franklin field, University of Pennsylvania, in 1927, the events were the 100- and 220-yd. dashes, the 440-, 880-, one-, and two-mile runs, the 100-yd. and the 220-yd hurdles, shot put, javelin throw, running high jump, pole vault, discus throw, running broad jump and hammer throw. A total of 707 athletes represented 31 colleges and universities. In the sixth annual indoor meeting (1927), held at New York city, 289 athletes from 23 universities and colleges contested in the 70-yd dash, 70-yd. hurdles, one-mile and two-mile runs, one-mile, two-mile, and freshman medley relays, and broad jump, pole vault, high jump, shot put, and 35-lb weight event. The heavier men, outclassed on the flat and in the jumps, were given another event on the introduction of the 35-lb. weight throw in 1922. The addition of the javelin and discus events to the programmes since 1922 is ascribable to their inclusion in the schedules of the Olympic games

Among record-holders S W Carr (Yale) broke the world's record in the pole vault by vaulting 14 ft at the outdoor meeting of 1927. Clarence W. Houser (University of Southern California), holder of the world's discus record and Olympic champion in the same event, established the I.C A A.A A record for 151 ft. 3⅝ in in 1926. John Paul Jones (Cornell) in 1913 established the American college record for the mile run, 4 min. 14⅖ sec A large proportion of the winners of points for the United States in the Olympic games have previously competed in the meetings of the I C.A A A A

The Amateur Athletic Union (1888) assumes jurisdiction over track and field sports in the United States (*see* ATHLETIC SPORTS *United States*) Its amateur definition, the competitor's qualification requirement (*see* AMATEUR), while rigid, is substantially the same as that of the I C.A A A A The A A U holds annual national championship meets the schedules of which have been extended to include the javelin, discus and all-round events as affording opportunity for preparation for the Olympic games

Certain college conferences and organizations also administer track and field competitions The National Collegiate Association, which was originally organized primarily as an advisory body, has held (1928) seven annual outdoor meetings Its programme is practically identical with that of the I C.A A A A. as regards the nature of the events The N C.A A meeting at Chicago in 1927 was entered by 183 athletes from 64 colleges and universities The association affords to colleges, particularly those of the middle West and South, an opportunity for track and field competition that would otherwise be lacking. Its meetings are open to all and occasionally a few of the athletes who have competed in the I C.A A A.A. championships compete also in the meet of the N C A A. The Intercollegiate Conference ("Western Conference" or "Big Ten") has conducted some 28 annual outdoor championship track and field meetings at the last of which the programme was composed of the same events as the I C.A A A A. outdoor and the N.C.A.A schedules. Its record-holders have included such college athletes as C R. Brookline (Iowa), De Hart Hubbard (Michigan), and others. All of these conferences and associations have followed the I C.A A.A A in definition, purposes and schedules of events.

American Schoolboy Track and Field Sports.—Many college athletes have taken lively interest in the schoolboy sports of their local residential communities. Through this interest have grown up numerous organizations of public spirited citizens who co-operate with municipal authorities to provide playing space,

equipment, training and competition in track and field sports for schoolboys and thus contribute to the national welfare. The pioneer in this field is the Public School Athletic League of the City of New York, founded in 1903. In the greater city of New York, each year half a million boys are provided with some form of athletic competition, the majority being engaged in track and field sports. Over 5 million have been trained since the league's organization.

The experiences of the I.C.A.A.A.A. with college youths and of the P.S.A.L. of New York city with elementary and high schoolboys have provided a stimulus to the widespread development of track and field sports in America. Cities and villages, the nation over, are organizing schoolboys for track and field sports along the lines of the P.S.A.L. of New York city. The principal features of the work of the P.S.A.L. have been the insignificant requirements of its equipment, the adjustment of some track and field sport to almost every boy's capacity, the absence of public hysteria surrounding the competition, and the lessons of discipline and democratic associations that have resulted.

See ATHLETIC SPORTS, separate articles on the branches of track and field sports, and various team games.

TRACTORS. The petrol (gasolene) tractor for agricultural and kindred purposes is a development of the steam traction engine, widely used for operating grain threshers and to a small extent for ploughing. Steam ploughs were used toward the end of the 19th century on the large ranches of the north-western section of the United States, in Canada and other regions involving such large scale production. Their usefulness was limited, however, owing to their great weight, which resulted in the packing of the soil and in rather inefficient operation. When the weight of the petrol engine was greatly reduced by motor-car engineers about 1900, the idea of substituting that type for the heavy steam plant naturally suggested itself. Early technical development was chiefly toward large tractors designed to operate from 6 to 12 plough bottoms, because at that time only owners of large ranches in western America showed an interest in power farming.

The large petrol tractors of that period were crude in design and very heavy; their frames were built of heavy rolled channels, and they had driving wheels of very large diameter. Their great weight naturally rendered them inefficient, for a large proportion of the engine power was consumed in moving the tractor itself.

AGRICULTURAL TRACTORS

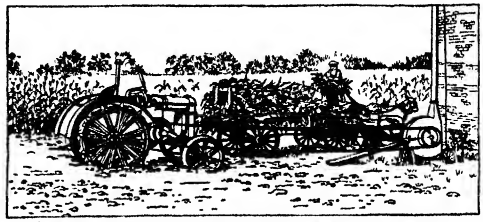
Tractors were usually rated according to the number of 14 in. plough bottoms they would pull. In 1927, of 77 models on the American market pulling two or more bottoms, 9 were two-plough tractors; 28, three-plough; 22, four-plough, and the remainder or 18, were capable of pulling five or more ploughs, up to ten. However, the tractors in the two-plough class were produced on the largest scale. Of the total of 178,074 wheeled tractors produced in the United States in 1926, 94,467 were one-plough and two-plough, while 45,523 had a rating of three-ploughs or two-to-three-ploughs. Table I shows the production of tractors in the United States.

TABLE I. *Tractor Production in the United States*

1910	4,500	1920	203,300
1912	11,400	1922	99,692
1914	10,400	1924	116,838
1916	29,670	1925	167,553
1918	132,697	1926	178,074

In 1912 the large tractors of 6 to 12 plough capacities reached their zenith, and thereafter declined rapidly. The first popular small tractor was produced the following year and in 1914 3,000 tractors of this small design were sold. Although smaller, it was still of the same crude design as the larger machines, with exposed gears, plain bearings and similar features. About 1916 a number of engineers with motor-car experience entered the tractor field, and as a result of their efforts tractor design was greatly improved.

Typical Design.—For the sake of economical manufacture many of the earlier small tractors were made with only three wheels, but the buying public did not approve of this feature of construction, and the typical 1928 wheeled tractor had four wheels, two in front for steering and two in the rear for driving. The Twin City 12–20 h.p. tractor shown in Plate I., fig. 1 is a good example of the lighter tractors based on motor-car practice.



A SILAGE CUTTER AND FILLER OPERATED BY TRACTOR POWER

The tractor industry was hard hit by the heavy slump in the prices of agricultural products late in 1920. Prices of tractors and other agricultural machinery did not drop nearly as rapidly nor as much as those of farm products, and the result was a "buyers' strike," the effect of which is clearly reflected in the production figure for 1922. A very keen price competition set in, and many tractor manufacturers went out of business during the next two years. With the improvement in the economic position of the American farmer the demand for tractors increased again, but the production record set in 1920 had not been equalled up to the end of 1926. During that year the exports of tractors from the United States amounted to 27% of the total production on a numerical basis and to nearly 25% on a value basis, the actual value of exports amounting to $29,561,023. A survey made by the U.S. department of agriculture in 1927 showed that there were then 29 concerns in the country manufacturing wheeled agricultural tractors and five manufacturing the crawler type.

The Fordson Tractor.—A tractor which was manufactured in very large numbers and distributed all over the world was the Fordson, manufactured by the Ford Motor Company, Detroit, Michigan. A central longitudinal section of this machine is shown in Plate I., fig. 2. It was of the frameless or backbone type, the crankcase of the engine and the cases of the change-speed gear and rear axle forming the supporting structure. The engine had four vertical cylinders of 4 in. bore and 5 in. stroke, which were cast in a single piece with the upper half of the crankcase, the lower half of this case being a separate casting. To the rear of the crankcase was bolted a housing which enclosed the flywheel, the friction clutch and the change gearing, and also formed the rear axle housing. There was no direct "through" drive, the power being always transmitted from the upper to the lower of two parallel shafts in the gearset, and an extension of the lower shaft carried the worm which meshed with the worm wheel on the rear axle differential gear.

Changing of gear was effected not by meshing the gears, which remained in mesh continuously, but by securing one or another of the gears to the shaft by positive clutches. The rear wheels were 42 in. in diameter and the tractor was geared to give a ploughing speed of 2¾ m.p.h. with an engine speed of 1,000 r.p.m. In addition to the ploughing speed there were provided two other forward speeds and a reverse motion. Over the engine was mounted a double-compartment fuel tank holding 1 gal. of petrol and 16 gal. of kerosene, the petrol serving to start and run the engine until the carburetter was hot enough to vaporize the kerosene. Air was taken in through an air washer and the carburetter in which the kerosene, after having been sprayed into a stream of air to form a very rich mixture, was vaporised by being passed between two stampings of sheet steel, the outer faces of which were in contact with the hot exhaust gases. Additional air was mixed with this rich mixture close to the inlet valves. Ignition was by a flywheel magneto, engine lubrication by the circulating splash system, and circulation of the cooling water by the gravity or thermo-siphon

system. Unlike most others, this tractor was not fitted with an engine governor by the manufacturer, but several speciality manufacturers offered governors specially designed for it and many owners of the tractor fitted them. The Fordson tractor had a wheelbase of 63 in. and weighed 2,562 lb. complete. The front axle was swivelled at its centre on a saddle casting bolted to the front of the engine and was braced near its ends by radius rods with flexible joints extending to lugs cast on the bottom of the engine crankcase. A belt pulley for power work was provided and ran at engine speed.

General Features.—Belt pulleys formed a part of the equipment of practically all tractors, being used for operating threshing machines, wood saws, silo fillers, etc. Many tractors built after 1924 were equipped with power take-offs or auxiliary drives through gearing and shafting, which were used on the farm when hauling grain binders, corn pickers and spraying outfits; by sawmill owners for operating cut-off saws and edgers, and by road builders for operating concrete mixers. It was customary to apply a double horsepower rating; for instance, a three-plough tractor was often rated as a 12–25 h.p. machine. This signified that the tractor could develop 25 h.p. on the belt and 12 h.p. on the drawbar, the difference of 13 h.p. being required for moving the tractor itself over the field.

Crawler Tractors.—The crawler (British term "caterpillar") tractor had one or two continuous-chain tracks on which it ran. The outside tread of the chain track in contact with the ground had transverse projecting bars or depressions which caused it to grip the ground firmly, while the inside tread of the chain formed a smooth track on which rolled idler wheels mounted on the frame and carrying the weight of the tractor. The power from the engine was transmitted through a suitable reduction gear to a pair of toothed wheels which engaged with teeth or rollers on the inner side of the track and, when power was applied by letting in the clutch, the tractor rolled ahead on the track and the track at the same time rolled forward The power was applied to the two chain wheels through a differential gear, and in order to steer a tractor of this kind, one track was held stationary by a brake on the shaft of its chain wheel, while all the power was applied to the other chain wheel.

The Cletrack tractor shown in Plate I., fig. 3, was one of the smallest tractors of this type. Much of the development work in connection with crawler tractors was done in California, where the Holt, the Best and the Yuba, all tractors made in large sizes, originated. In 1927 many of these large crawler tractors were used for other than agricultural purposes—for example, in oilfields, in lumbering and in road-building. The city of New York in 1920 purchased a large number for use in clearing the streets of snow. The lumbering or logging work done was mainly in swampy districts where horses cannot work except in winter when the ground is frozen, whereas the crawler tractors make logging in such districts possible the year round. The weight on the track of a crawler tractor of the 1927 type was as low as 5 lb. per sq in., and such a tractor could go into boggy places where no wheeled vehicles could follow.

Cost and Uses.—The three chief items of cost in tractor ploughing are fuel, depreciation and labour. At the tractor trials held at Lincoln, England, in the autumn of 1919, the fuel consumption per acre averaged almost exactly 4 imp. gal. for ploughing in heavy clay soil, and 3 gal. for ploughing on cliff lands. In the corn belt of the United States, where the soil is comparatively light, it has been customary to reckon on a fuel consumption (either petrol or kerosene) of 2·5 U.S. gal. (2 imp. gal.) per acre. On the other hand, in a *Bulletin* of the U.S. dept. of Agriculture on "The Gas Tractor in Eastern Farming," a fuel consumption of 3½ U.S. gal. per acre is made the basis of cost calculations for the eastern section, and in the tractor trials held at Harrisburg, Pa., in 1919, the average fuel consumption of all tractors using kerosene worked out at 3·28 U.S. gal. (2·62 imp. gal.) per acre. The fuel consumption in tractor ploughing varies both with the character and condition of the soil and with the depth of ploughing. The average depth of ploughing at Lincoln was 5¼ inches. The resistance of the soil (drawbar pull) averaged 11·5 lb. per sq.in. for the heavy clay soil and 9 lb. per sq.in. for the cliff land. In the corn belt of the United States the soil resistance generally varies between 5·5 and 7 lb. per sq.in., and this explains the low fuel consumption in ploughing there. The estimate here given of the cost of ploughing one acre is based on the results of an inquiry by the U.S. dept. of Agriculture among 400 tractor farmers in the Dakotas concerning their experiences in 1917 and 1918. Only one change is made from the estimate of the department, namely, the assumption of a tractor life of seven instead of nine years.

TABLE II. *Average Cost and Performance of Tractor Ploughing in the Dakotas*

	Two-plough tractors	Three-plough tractors	Four-plough tractors
First cost	$1,050	$1,460	$2,000
Full working days per year	45	52	64
Acres ploughed per 10-hr day	6·3	8·5	10·9

Other factors on which the estimate is based are the following: cost of petrol, $0 276 per U.S. gal ; kerosene, $0.152 per gal ; lubricating oil, $0.50 per gal.; grease, $0 10 per lb.; repairs, 4% of the first cost per year; depreciation on a 7-year basis; man labour at $4 00 per day; interest at 6% on the average investment (one-half of total investment). Such items as housing, insurance and taxes are neglected

TABLE III. *Cost of Tractor Ploughing in the Dakotas, 1917–18*
(Dollars per acre)

Size of tractor	Total cost of ploughing		Fuel		Oil
	Gasolene tractor	Kerosene tractor	Gasolene	Kerosene	
Two-plough	2·21	1·915	0·69	0·395	0·075
Three-plough	1·975	1·680	0·69	0·395	0·075
Four-plough	1·757	1·462	0·69	0·395	0·075
Other Items					
	Grease	Repairs	Depreciation	Man labour	Interest
Two-plough	0·02	0·15	0·53	0·635	0·11
Three-plough	0·02	0·13	0·49	0·470	0·10
Four-plough	0·02	0·11	0·409	0·368	0·085

With these data a close estimate can be made of the cost of tractor ploughing under different conditions, as all the basic costs are given. The average soil resistance in the Dakotas may be assumed to be 8 lb. per sq. inch. In heavier soils the area ploughed per day will be less in substantially the inverse ratio of the soil resistance (provided the latter is not excessive). This is borne out by estimates of the ploughing capacities of the tractors which competed in the Lincoln trials of 1919. Averaging the estimates for heavy clay soil (soil resistance 11·5 lb. per sq.in.), and reckoning on the basis of a 10-hr. instead of an 8-hr. day, the following results are obtained: two-plough tractor, 4½ acres, three-plough tractor, 5⅝ acres, four-plough tractor, 6¾ acres.

Advantages.—To the American and Canadian farmer the advantage of the tractor is not so much that it reduces the cost of ploughing as compared with horses, as that it enables one man to work a much greater acreage. Approximately one-third of several hundred tractor farmers in Illinois circularised by the U S. Dept. of Agriculture had increased their acreage by purchasing tractors. Another great advantage is that the tractor permits work to be done quickly when the weather is favourable. Power farming has proved particularly advantageous in the wheat belt of Kansas where for the best yield the land must be ploughed in August, when the temperature is often above 100° F in the shade and very little work can be accomplished with horses. The tractor works as efficiently at this temperature as in winter. Moreover, the tractor can be used also for threshing, and the old practice of contract threshing has been largely superseded by the plan of four or five farmers owning a small threshing machine co-operatively

and helping each other thresh their grain, each using his own tractor as the motive power. Sometimes it is necessary to get a crop into the ground very quickly, and, with a double shift of operators, tractors can then be operated day and night.

Tractor for Row-crop Farming.—The ordinary farm tractor was designed primarily for ploughing and is not suited to the cultivation of row crops, such as Indian corn, cotton, sorghum, etc. For this work a special type of motor cultivator was developed, and while a certain degree of success was achieved with it, most of the machines of this type brought out disappeared from the market. A compromise design, the Farmall (Plate I., fig. 4), was developed by the International Harvester Company. It had two steering wheels rather close together at the front, on opposite sides of a vertical steering column, designed to pass between adjacent rows; and two driving wheels at the rear, with a tread of 74 in., which was sufficient to straddle two rows of corn. At the front the frame was supported on the steering column above the front wheels (of 25 in. dia.), while at the rear the axle was arched, the center portion being considerably higher than the wheel spindles, giving an axle clearance of 30 inches. One of the objections to many items of farm equipment is that there is use for it only a few days per year and it lies idle all the rest of the time. An all-purpose machine of this type evidently overcomes that objection to quite an extent. A large variety of tools were especially designed and others adapted for use with the Farmall.

Tractors for use in orchards, on which a number of American manufacturers specialise, must be of lower build than those for general use. A distinct type is the garden tractor, for the cultivation of row crops and general work in market gardening The Beeman, the first tractor of this type, was put on the market in 1915, and in 1926 the total number of such tractors produced in the United States (by 13 manufacturers) was 3,921.

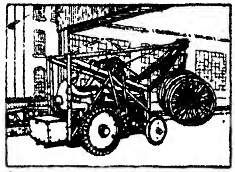
Development in Europe.—Interest in farm tractors increased greatly in Europe during and following the World War. In 1919 and 1920 tractor trials were held at Lincoln, England, the first under the auspices of the Society of Motor Manufacturers and Traders and the second under that of the Royal Agricultural Society. The French Government in 1920 paid a bonus of 25% on the purchase price of tractors of domestic manufacture and 10% on tractors of foreign manufacture. French engineers paid particular attention to tractors which must be very narrow for use in vineyards. Tractor development and application in Europe also received a severe setback about the time of the world-wide business depression of 1921, chiefly owing to the high-cost of the fuel. The tractor trials of the Royal Agricultural Society were not repeated after that date. To reduce the fuel cost item a number of compression-ignition type engines (Diesel and hot-bulb) were brought out, including the Avance in Sweden, the Lanz Acker-Bulldog and Benz-Sendling in Germany, and the Helios in Holland, these tractors using heavy liquid fuels.

In France efforts to reduce the fuel cost of tractors were directed along other lines, the machines being fitted with gas generators operating on charcoal or prepared solid fuels. Most of the tractors exhibited at the Paris Agricultural Show in 1928 had such generators. Considerable development work was done in Germany during the decade following the war, but most of it was along lines that had been covered previously in the United States. Prof. Gabriel Becker of the Charlottenburg Technical College made extensive tests and investigations on American and German tractors and published his results. The German Government in 1927 initiated a scheme for extending credit to farmers for the purchase of (German-built) tractors. The Soviet Government of Russia during the period 1925–1927 bought thousands of tractors from leading American firms and prepared to manufacture similar tractors in Russia.

INDUSTRIAL TRACTORS

These are machines designed for hauling trailer trucks over comparatively smooth surfaces such as railroad terminal and warehouse floors, steamship piers, etc. They were developed from industrial trucks which began to replace hand trucks on steamship docks and railroad platforms about 1904 Such tractors would haul a trailer load ranging from 5 to 20 tons, dependin upon the sizes, and so reduced to a great extent the manual labou required in handling freight and baggage at the terminals anc warehouses.

Industrial tractors for the above purposes generally were electrically driven, since the low fire hazard and the absence of exhaus gases characteristic of this system of drive recommended it fo indoor work. The wheel trea usually was around 30 in., and the wheelbase ranged from 40 to 48 in., while the wheels in most cases were 20 in. in diameter and equipped with solid rubber tires Although the earliest industrial tractors were steered by the front wheels, and were driven by the rear wheels, later designs fre quently were provided with a four-wheel drive and a four-wheel system of steering; the forme to give a sufficient traction even on slippery (oily or icy) surfaces and the latter to manoeuvre the trains more advantageously in restricted spaces.



A POWER WINCH MOUNTED ON A TRACTOR

Four-wheel-drive tractors were usually equipped with four-wheel brakes, which made it possible to stop them quickly in an emergency. Speeds ranged from 6 to 8 m.p h. when light, and around 4 m.p.h. when loaded. On fairly smooth surfaces the trailer trucks required a drawbar pull of approximately 50 lb. per ton. With the usual construction the normal continuous drawbar pull obtainable was about 10 per cent of the total weight of the tractor with battery. The weight of the battery amounted to 30 to 35 per cent of the total tractor weight.

Generally the operator steered by means of a lever or tille which folded out of the way when he left his seat. Three speeds in both directions were obtained by means of a controller. For safety purposes, the main switch, controller and brake were interlocked. Before the tractor could be started a pedal had to be depressed. When the operator withdrew his foot from the pedal the main switch opened and the brake was applied automatically. This tended to prevent accidents, as the tractor would come to a stop if the driver were thrown from his seat. The battery voltage used to drive the tractors was either 32 or 48 volts

ROAD TRACTORS

The road tractor (or tractor-truck, as it is often called in the United States) was developed from the lorry. It differs from the latter only in having a shorter wheelbase and in that, instead of being provided with a platform or other body for carrying loads, it is fitted with a bolster on the frame over its rear axle which carries the forward end of a semi-trailer through a fifth wheel Whereas in the conventional lorry nearly all of the useful load is carried on the rear wheels, in a tractor-trailer combination it can be equally divided between the rear wheels of the tractor and the two wheels of the trailer, so that a much greater load can be carried. Moreover, by far the most expensive part of the combination is the tractor, and this need not be kept idle during periods of loading and unloading, but can be kept busy all the time, providing a sufficient number of trailers is available. When the semi-trailer is being loaded or unloaded its forward end rests on jacks or folding supports with caster wheels. Coupling of the semi-trailer to the tractor is effected automatically by simply backing the tractor up to the trailer, and uncoupling is an equally simple operation. Road tractors for hauling semi-trailers have been built with electric, steam and petrol power-plants.

belonged to a noble family of Scotch descent, settled in France in the 15th century. He studied at Strasbourg, entered the army, and when the Revolution broke took an active part in the provincial assembly of Bourbonnais. He was elected a deputy of the nobility to the states-general, where he sat with his friend La Fayette. In the spring of 1792 he received the rank of *maréchal de camp* in command of the cavalry in the army of the north; but when the Left became predominant took indefinite leave. He settled at Auteuil, where, with Condorcet and Cabanis, he devoted himself to scientific studies. Under the Terror he was imprisoned for nearly a year, during which he studied Condillac and Locke, and abandoned the natural sciences for philosophy. As an associate of the Institute he wrote the papers which formed the first draft of his comprehensive work on ideology. The society of "ideologists" at Auteuil embraced, besides Cabanis and Tracy, Volney and Garat (1749–1833), professor in the National Institute. Destutt de Tracy died in Paris on March 9, 1836.

Destutt de Tracy was the last eminent representative of the sensualist school which Condillac (*q.v.*) founded in France upon a one-sided interpretation of Locke. He pushed the sensualist principles of Condillac to their last consequences, being in full agreement with the materialistic views of Cabanis, though the attention of the latter was devoted more to the physiological, that of Tracy to the psychological or "ideological" side of man. His ideology, he frankly stated, formed "a part of zoology," or, as we should say, of biology. The four faculties into which he divides the conscious life—perception, memory, judgment, will—are all varieties of sensation As a psychologist de Tracy deserves credit for his distinction between active and passive touch, which developed into the theory of the muscular sense. His account of the notion of external existence, as derived, not from pure sensation, but from the experience of action on the one hand and resistance on the other, may be compared with the account of Bain and later psychologists. His chief works are *Eléments d'idéologie* (1801–15; 2nd ed, 1824–25), *Commentaire sur l'Esprit des lois de Montesquieu* (1806, 5th ed., 1828; Eng. trans., President Jefferson 1811), *Essai sur le génie et les ouvrages de Montesquieu* (1808).

See F. Picavet, *Les Idéologues* chs. v. and vi. (1891), V. Stepanowa, *Destutt de Tracy, eine historische psychologische studie* (Zürich, 1908).

TRADE. *See* COMMERCE, TRADE; WORLD STATISTICS; BALANCE OF TRADE; FREE TRADE; PROTECTION; TARIFFS; TRADE ORGANIZATION; and also the sections dealing with trade and commerce under the various countries. For the English Board of Trade, *see* GOVERNMENT DEPARTMENTS; for international trade congresses, *see* INTERNATIONAL TRADE ASSOCIATIONS AND CONGRESSES; for trade disputes, *see* STRIKES AND LOCKOUTS.

TRADE, PRIMITIVE. The importance of trade to primitive races is seldom realized. Exchange of goods among them is certainly limited in extent; often only specified classes of objects are allowed to change hands, and many commodities are exempt from such traffic, as the land of the clan or tribe. Nevertheless trade, *i.e.*, a regular series of acts of exchange, is a distinct feature in the life of primitive peoples, even the lowest, who live by hunting and collecting forest products. The principle of reciprocal transfer of goods, of giving and taking, seems in fact to be deep-rooted in human nature.

Trade has two aspects, intra-communal, between members of the same community, and extra-communal, between members of different communities. The latter is of more interest, especially since, by the widely accepted theory of Karl Bücher, those few primitive folk who have advanced beyond the pre-economic stage of existence are still in a state of closed household economy. Each little group is imagined as self-sufficient, its needs and products in equilibrium, and trade between them, being unnecessary, is therefore held to be absent. More adequate study, however, shows that this idea is quite erroneous.

Types of Trade.—1. Most spectacular is the institution variously described as the *silent trade*, "dumb barter" (*Stummer Handel*) or depot trade (*Le Commerce par dépôts*). Mentioned by Herodotus, this method of exchange was practised by the Carthaginians in their traffic for gold with the African tribes beyond the Pillars of Hercules, and was noted by Fa Hien, Ibn Batuta and other early travellers. In the most general form of procedure one party goes to the customary spot, lays down goods and retires into the bush or to a distance, giving as a signal a call or a gong-stroke. The other people then come, lay down what they consider to be articles of equivalent value, and retreat in their turn. The first party then comes back and if satisfied with the bargain removes the newly-deposited goods; if not, these are allowed to remain until suitable additions are made. The people of the second party then take away the original wares and the transaction is concluded Neither party holds any communication with the other, beyond giving the customary signal, hence the name of "silent trade." This widespread institution is reported from such diverse regions as north Russia, Lapland, west Africa, Timor, Sumatra, India, Ceylon and north New Guinea. It is found especially where people of a fairly primitive type conduct habitual exchange with those of a somewhat higher culture. Thus the Akka pygmies obtain bananas in exchange for meat from neighbouring agricultural tribes, and the Veddah obtain iron implements from Singhalese smiths in return for game. Elements of shyness and fear are obviously involved in this custom, which thus secures economic benefits for people who shun foreign contracts

2. In the *gift-exchange* the transaction takes the form of present and counter-present often between host and guest. A good example is afforded by the Maori of New Zealand. Exchange was conducted quite in the manner of gift-making; no bargaining upset the proceedings; such was not *tika* ("correct"). At the same time a very strict system of reciprocity was in force, by which the recipient of the gift was bound, as he valued his name and reputation, to make adequate repayment. This was expected by the donor Such was the idea of *utu*, equivalence, which ran through all Maori social life. But the recipient usually tried, if possible, to give back greater value than he received, not through generosity, but since his own prestige would thereby be enhanced. Even where the exchange was primarily a matter of securing necessaries of life, as food or garments, the desire to obtain fame by being liberal strove with the wish to have the economic advantage. As Malinowski, Thurnwald, Radcliffe-Brown and Raymond Firth have shown, these are the twin psychological factors lying at the root of every exchange of gifts.

3. *Barter* consists in the direct transfer of goods against goods Unlike the gift exchange, it implies agreement as to rates, with the possibility of haggling over quantities and values. A system of barter in certain commodities may co-exist with gift-exchange in others of greater social import, as in the Trobriands, where, as described by Dr. Bronislaw Malinowski, the *Kula*, or exchange of valuable arm shells and necklaces is conducted along polite, strictly ceremonial lines, while the *gimwali*, the barter of fish for vegetables, is carried on with haggling as to size and quantity, and even acrimonious wrangling. Barter in abstract form is often supposed to be typical of primitive peoples. But very rarely in any native community is the rate of exchange for goods determined by purely economic considerations of supply and demand working on the principle of rational utility alone.

4. *Buying and Selling* avoids the awkwardness of barter by the use of some medium of exchange. Much of what is often described as "primitive money" is wrongly so termed, but in various parts of Africa, for instance, cloth, iron, cowrie shells and salt do act as true currency, as also, apparently, do coconuts in the Nicobar islands. (*See* CURRENCY, PRIMITIVE.)

Occasions of trade on a large scale among primitive peoples are provided by expeditions and markets.

Trading Expeditions.—In some areas itinerant traders, as the Hausa hawkers in parts of Africa, play an important rôle in economic life. In others their place is taken by caravans, as those of the Arabs, regularly equipped and following recognized trade routes. Of great interest, again, as being accomplished by more primitive folk, are such group expeditions as those of the Dieri and other Central Australian tribes, who will travel on foot for 400–500 miles to procure red ochre and the *pituri* plant. Noteworthy also are the trading voyages, in unwieldly dug-out canoes,

of the people around the New Guinea coast, as the sailing trips of the Siassi of the North, the *hiri* of the Motu, in which pots are taken to the Papuan gulf and exchanged for sago, and the *Kula* of the Trobriands, the ceremonial exchange of valuable ornaments.

Primitive Markets are of varied kind and wide distribution. Their great home is Africa, but they have also been described from Guiana, old Mexico and Peru, Hawaii and various Melanesian areas. A typical example at either end of the scale will serve for illustration. The inhabitants of certain small islets off the coast of Malaita, Solomon islands, barter fish with those of the mainland for vegetables and pigs. Almost every day at times arranged beforehand with the bush natives, the islanders resort in their canoes to recognized places on the beach. The men then stand guard with spears, while the actual bartering is done by the women, who, thus covered, advance slowly towards one another, produce in hand. Disputes at these markets are rare, though at other times the island natives cannot venture ashore without risk. In parts of Africa this institution is more imposing. Among the Akikuyu of the East, markets in a thickly populated district are no more than ¾ m. apart, and are of great importance in the life of the people. They occur very frequently in the week, but are so arranged as not to clash with others in the neighbourhood, so that a person may visit them all in turn. About 9 o'clock in the morning the paths begin to fill with natives carrying loads of corn, firewood, beer or iron to exchange, and between 11 and 1 business is at its height, the concourse numbering perhaps 4,000–5,000 people. Order is maintained by special officers and no weapons are allowed within the precincts. The main characteristics of a market as a mode of conducting trade are its set time and regular recurrence, the definite place of assembly and the regulations by which order is preserved.

Psychology of the Trading Process.—The motives behind primitive trade are many-sided. The central factor is undoubtedly the desire for rational gain, for securing objects of economic utility otherwise unprocurable owing to variations in natural conditions or specialized skill. But the psychological background is more complex than this. Trade is often carried on in articles charged with great social and ceremonial meaning, as in ornaments, but of no direct practical interest. Moreover, the desire for renown and prestige is often a prominent element in the exchange, while the transaction itself may assist in cementing social bonds.

The value of goods, too, is determined by a complex set of factors. Even in the case of things apparently desired merely for their practical utility there is not such an objective standard of valuation as obtains in modern society, *i.e.*, personal factors enter much into the exchange. The extent to which emotional elements lie at the root of value is shown in the case of such objects as *tiki* and other greenstone ornaments of the Maori, heirlooms of great wealth and the principal articles of ceremonial exchange. Their worth lies in their historical association with dead chiefs and ancestors of renown, in their sacredness and importance as symbols of the tribal greatness rather than in their practical use for adornment.

Theory of Primitive Trade.—The principal types of trade in primitive culture were once regarded as successive products in evolutionary development. Modern research, however, tries to study each particular system of trade in its own cultural setting. The primitive market in its various forms, for instance, cannot be understood if conceived simply as an evolutionary sequence from the customs of silent trade (Grierson) or as a development from previous hostile relations (Müller-Lyer) or as the result of a recurring assemblage of people for religious or ceremonial purposes (Ling Roth). It is explicable only as an institution *sui generis* which emerges in response to certain needs, and is conditioned by the natural situation and the social structure of the community which it serves. So also with primitive trade in general. It is more than a mere matter of economic trafficking on abstract principles of national advantage; it is a complex social mechanism linked to many aspects of native life. The true problem does not lie in theorizing about its historical or evolutionary origins but in disentangling the various social and psychological factors which together determine the form of the living institution.

TRADE: WORLD STATISTICS. 1. The 16th, 17th and 18th Centuries.—The sea is the great highway of international commerce and it was the discovery of the Cape of Good Hope route to the East Indies and the discovery of America at the end of the 15th century which opened the world to commerce. Before that time the spices, sugar, silk and other luxuries of the East came into European hands only when they had filtered overland to the seaboards of the Mediterranean and Black seas. Thus the carrying trade of Europe was focussed in the Mediterranean, and in the fifteenth century Venice had established herself as the great market and carrier of Europe. Statistics relating to these early times are far between and generally unreliable, but it is said that Venice, at the height of her glory in the 15th century, could dispose of 3,300 ships, 36,000 mariners and 16,000 dock hands. The number of the crew was in proportion to the burthen, one man for every 10,000 lb. of capacity, so that the carrying capacity of the fleet may well have approached 150,000 tons. Complementary to the eastern trade route was the western route extending by sea to the ports of England and Flanders; thus Venetians exchanged the luxuries of the East for the wool and woollen cloth of the North. Further north, the carrying trade was largely in the hands of the Hanseatic League

With the discovery of the Cape route to the Indies, the centre of trade shifted from the Mediterranean to the western seaboard of Europe. The Portuguese were bending all their energies to the development of the Indian sea-route and, by the end of the 15th century, the Dutch had established their supremacy in the carrying trade and Amsterdam had become the emporium of Europe.

As Sir Walter Raleigh showed in 1603 in his famous *Observations concerning the trade and commerce of England with the Dutch and other foreign nations,* it was largely owing to the development of their herring fishing industry, which trained both sailors and shipbuilders, that the Dutch were able to become the great carriers of Europe's trade. They maintained this position till the end of the 17th century when the wars in which they were involved, together with the economic development of England and France, destroyed their trade supremacy.

Sir William Petty in one of his essays on "Political Arithmetick," published in 1690 but written some years earlier, gives some interesting estimates of Europe's mercantile marine at that time. He wrote, "The value of the shipping of Europe, being about two Millions of Tons, I suppose the English have Five Hundred Thousand, the Dutch Nine Hundred Thousand, the French an Hundred Thousand, the Hamburgers, and the subjects of Denmark, Sweden, and the Town of Dantzick Two Hundred and Fifty Thousand, and Spain, Portugal, Italy, etc. Two Hundred and Fifty Thousand." Later in the same essay, he estimates the total value of the merchandise carried by Europe's shipping at £45,000,000 a year. Petty appears to have based his estimates of shipping on one seaman being required for every ten tons of shipping. He probably meant to include Scotland and Ireland with England but even so his figure of 500,000 tons appears to be on the high side. The first complete return of England's mercantile marine was obtained by the commissioners of customs in 1701–2, when it appeared that there belonged to all the ports of England and Wales 3,281 vessels, measuring (or rather supposed

to measure) 261,222 tons and carrying 27,196 men. By 1760, on the eve of the industrial revolution, the number of vessels had grown to 6,105 of the reputed burden of 433,922 tons, while in addition there belonged to Scotland 976 vessels of 52,818 tons.

There is one exception to the general absence of real statistics of shipping in the age before the industrial revolution. From about the year 1429 all vessels passing the Sound were liable to pay dues to Denmark and particulars of each ship passing, varying from time to time in their detail, were entered in the records. Some of the earlier records are missing but two volumes entitled *Tables de la Navigation et du Transport des Marchandises passant par le Sund, 1497–1660,* edited by Fröken Nina Bang, contain the available information. The figures naturally reflect the commercial progress of the countries bordering on the Baltic. The first two years for which the records are extant are 1497 and 1503; averaging these two years, the number of vessels passing the Sound (each vessel is counted both outwards and inwards) was 1,009 of which 712 were Dutch and most of the rest belonged to the Hanseatic towns. In the ten years 1538–47 the average number of ships a year was 1,442. The average annual number in each decade then rose steadily till the end of the 16th century, being 5,623 vessels per annum in the years 1590–99 Then the numbers fell off again and in the period 1650–57 averaged only 3,015 per annum. Throughout the period, with rare exceptions, over half the vessels were Dutch and usually about two-thirds of them were Dutch. From 1536 to 1645 the Dutch vessels are shown according to their capacity—over 100 lasts (a last is about 2 tons), 30–100 lasts, and under 30 lasts About 40% of the Dutch vessels were recorded as over 100 lasts in the early years but thereafter the proportion so recorded fell off. About the year 1618, however, the regulations appear to have been tightened up and in the following decade about half the Dutch vessels were recorded as over 100 lasts. Thereafter the proportion of vessels of over 100 lasts increased and accounted for about 90% of all vessels in the period 1640–45. Throughout the period the number of English and Scottish vessels rarely exceeded 10% of the total

In the century or so preceding the industrial revolution, the development of international trade was normal in degree, depending mainly on the increase of population and any cheapening in transport caused by improvements in the arts of navigation and shipbuilding. Nations were on the whole self-dependent for the means of livelihood of their people and international commerce consisted of the exchange of surplus products for luxuries from other lands But with the industrial revolution all this was changed. First England and later other industrial countries became essentially dependent on external trade. Manufactures were made largely from imported materials and the industrial population tended to depend more and more on imported supplies of foodstuffs, both received in exchange for exports of manufactures. International trade increased at a tremendous rate. About the middle of the 19th century a further great stimulus was given to commerce by the cheapening and acceleration of transport through the development of the steamship and the railway.

We have already seen that in 1760 the reputed burden of the vessels belonging to England and Wales was 434,000 tons. By the year 1800 the figure had grown to 1,467,000 tons, in spite of severe losses in the war with France. The tonnage of all vessels entering and clearing ports of Great Britain from or to foreign countries also increased about fourfold in this period of 40 years. On the other hand the wars practically destroyed the carrying trade of Holland. Reverting for a moment to vessels entering and leaving the Baltic, the numbers passing the Sound in certain years were as given in the table in the next column.

Vessels Passing the Sound in Certain Years

Flags	1772	1791	1798
Dutch	2,145	1,736	None
British	1,894	3,720	3,313
Danish	973	1,394	1,825
Swedish	805	1,816	2,120

Other flags	537	1,356	629
Total	6,680	10,452	9,508

2. Commerce of the United Kingdom, United States, France and Germany to 1913.—In the foregoing sketch of the development of commerce up to the end of the 18th century, the carrying capacity of shipping has been our best guide. With the development of trade in highly manufactured and valuable articles occupying comparatively little space, shipping capacity becomes a less satisfactory measure; a ton of coal or of iron ore and of cotton piece-goods or machinery have values of quite different orders. About the same time figures of the total value of imports into and exports from the principal trading countries become available and, as late as 1880, about 75 per cent. by value of the goods passing in the trade of world were imports or exports of the United Kingdom, the United States, France and Germany.

In interpreting figures of value the effects of changes in the level of prices must be borne in mind. The following table shows the fluctuations in general prices in the United Kingdom at ten-yearly intervals between 1791 and 1926, as shown by Jevons' index numbers from 1791 to 1846 and Sauerbeck's index numbers from 1846 to 1926 The average of the years 1867–77 is taken as 100 and the two series have been linked on the respective index numbers in the year 1846.

1791	107	1871	100
1801	168	1881	85
1811	164	1891	72
1821	113	1901	70
1831	99	1911	80
1841	102	1921	155
1851	75	1926	127
1861	98		

At the time of the revolutionary and Napoleonic wars prices increased very greatly. After the wars, prices drifted downwards on the whole till about 1850 In the next 25 years they moved upwards reaching a high point (111) in 1873 but dropped back again in the last quarter of the century to some 30 per cent. below the datum line Prices then increased steadily till the outbreak of the World War. The effect of the war was to increase them very greatly, but since 1920, there has been a substantial fall in the general level, as there was after the wars a century earlier.

(*a*) *The United Kingdom* —A systematic record of the official value of the imports into and exports from England from 1699 to 1778, the same for Great Britain from 1779 to 1800, and for the United Kingdom from 1801 to 1853 is given in *Custom Tariffs of the United Kingdom, 1800–1877* (1897) The official values were based on the old valuations laid down at the end of the 17th century. It follows that, while they may afford a basis for estimating the volume of trade from year to year, they give no correct idea of the value of the trade of each year at current prices In 1798, however, an *ad valorem* convoy duty was imposed on domestic exports and this made it possible to ascertain the real current value of exports. For imports and re-exports, it was not till 1854 that the old official values gave way to current values. Trade with Ireland is excluded from the following figures throughout.

Around the year 1700 the official value of imports into England was about £5,500,000 and that of exports about £6,000,000. During the next 60 years the figures increased slowly but steadily and around 1760 were about £8,500,000 for imports and £13,000,000 for exports. From 1760 to 1785 imports continued to grow, exceeding £14,000,000 in the latter year, but exports remained stationary. In the next 15 years, however, both imports and exports about doubled. From the beginning of the 19th century the figures relate to the United Kingdom and about the same time real values become available for exports of domestic produce and manufactures. In the year 1805, the official value of the imports was £28,561,000 and that of the exports £31,064,000, of which £23,377,000 represented exports of domestic produce and manufacture and the remainder exports of imported merchandise; the real value, however, of the domestic exports was £38,077,000, *i.e.*, about 60 per cent. above the official value.

The volume of imports, so far as it can be judged on the basis of these official values, remained about steady from 1805 to 1822, doubled in the next 15 years and again about doubled in the fol-

lowing 15 years (up to 1853). The official values of British exports in this period have little significance beyond illustrating, by comparison with the real values, the enormous decline in the prices of our exports, due partly to the general fall in prices and partly to the effects of the development of the factory system in cheapening manufacturing costs While, as shown above, the real value in 1805 was over 60% above the official value, by 1840 the real value was only half the official value: in other words export prices in 1840 were, on average, less than one-third of what they had been 35 years earlier. The real value of domestic exports was £36,966,000 in 1822, £47,381,000 as late as 1842 and then increased rapidly to £98,934,000 in 1853. The following table shows the real value of the domestic exports, and of the retained imports (*i.e*, total imports less re-exports) in annual averages from 1855 to 1913, together with the population.

Annual averages	Retained imports	Domestic exports	Population
	Million £	Million £	Millions
1855–9	146·1	116·1	28·2
1860–4	193·8	138·4	29·2
1865–9 . . .	237·7	181·1	30·4
1870–4	290·6	234·8	31 9
1875–9 .	319·5	201·5	33·6
1880–4 . . .	343·6	234·3	35·2
1885–9 . .	318·8	226·2	36·6
1890–4 . .	357·1	234·4	38·2
1895–9 .	392·7	237 8	40·0
1900–4 .	466.1	{ 282·8 / 288·7* }	41·9
1905–9	522.1	377·3*	43·7
1910–3	611.0	474 2*	45·5

*Including value of exports of ships and boats (new) with their machinery recorded from 1899 only.

Throughout the period shown in the table imports have consistently exceeded exports in value This difference has been more than made up by receipts from such items as shipping earnings and returns from overseas investment

Considering first domestic exports, there was a very rapid rate of progress up to 1872, when the figure of £256,000,000 was reached. In the next 25 years there was comparatively little increase in values, owing partly to increased competition from other countries which were now manufacturing on a substantial scale and partly to the fall in prices Then followed a period of rapid expansion till 1913 when the figure was £525,000.000 In 1854, 90%, by value, of the domestic exports consisted of articles wholly or partly manufactured, while in 1913 the proportion of manufactured articles had fallen to 78% of the total Exports of coal accounted for a considerable proportion of the remainder

The course of retained imports was similar. Their value was £134,000,000 in 1854 and increased rapidly to £315,000,000 in 1873; then till 1895 progress was slow, the figure in that year being £356,000,000, but thereafter there was, on the whole, a rapid increase till 1913 when the figure of £659,000,000 was reached Of the retained imports, only 15% in 1854 consisted of articles wholly or partly manufactured, but by 1913 the proportion had increased to 25 per cent The great bulk of the imports consisted of foodstuffs and raw materials of industry, raw materials predominating in the earlier years, and foodstuffs (including drink and tobacco) from about 1875

In 1855–9 imports and exports per head of population averaged about £9.5s and by 1870–4 the figure had grown to about £16. As late as 1895–9 the figure was still about £16, but by 1910–13 it had increased to nearly £24

(*b*) *The United States*—Figures of the value of imports and exports are available for the United States as far back as 1790. At that time the population was rather under 4,000,000 and being concentrated mainly on the seaboard, was more dependent on overseas trade than later when the internal resources of the continent were developed This is reflected in the trade statistics. In the decade 1790–1800 the value of imports and exports together averaged $22 per head of population; and in the decade 1821–30 the value per head dropped to rather under $10. The value per head then gradually increased to about $25 in the period 1871–80. Thereafter there was a set-back and progress was not resumed till the beginning of the present century. On the annual average of the years 1910–13, the imports and exports per head had increased to $39.

But while the external trade per head of population has been comparatively small, the aggregate value of the trade has increased enormously, owing to the rapid rate of the growth of population. In the decade 1790–1800, imports and exports together averaged annually $100,000,000; in 1821–30 the annual average was $142,000,000; and in 1841–50 it had increased to $244,000,000. The following table shows the value, both in dollars and sterling, of the domestic exports and the retained imports in five-year annual averages from 1850 to 1913, together with the population·

5-year annual averages	Retained imports		Domestic exports		Population
	Million dollars	Million £	Million dollars	Million £	Millions
1855–9	288·0	59·2	256·9	52 8	28 9
1860–4	266·0	54·8	208 7	42·9	32·7
1865–9	354·7	72·9	221·4	45·5	36·2
1870–4	550·8	113·2	468·1	96 2	40·6
1875–9	468·1	96·2	606 8	124·7	46·4
1880–4	681·7	140·1	804·8	165 4	52·5
1885–9	677·8	139 3	711·4	146·2	58·7
1890–4	791·7	162·7	898·7	184·7	65·1
1895–9	708·0	145·5	1,034·5	212·6	71·6
1900–4	905·1	186·0	1,422·4	292 3	79·0
1905–9	1,247·7	256·4	1,730 9	355 7	87·3
1910–13	1,624·3	333 8	2,109 5	433·5	94·6

Up to the year 1873 the value of imports exceeded that of exports, in spite of the fact that the United States authorities value imports in the country of shipment and so exclude the freight and insurance charges from the recorded values This excess of imports was mainly due to the fact that the United States was borrowing large amounts of capital from Great Britain for purposes of internal development; another reason is that the United States was still earning considerable sums from its mercantile marine, since the era of wooden ships, of which they had a large merchant navy, was not yet over From 1873 to 1895 exports only slightly exceeded imports in value, but in the next ten years exports developed more rapidly than imports From 1905 to 1913 both imports and exports increased at about the same rate

The following table shows the relative distribution of (1) foodstuffs (crude or manufactured), (2) raw materials for industry and (3) articles wholly or partly manufactured among the total imports and domestic exports from 1860 In the thirty years before that date the changes were comparatively small

Years ended June 30	Total imports			Domestic exports		
	Food-stuffs	Raw materials	Manufactures	Food-stuffs	Raw materials	Manufactures
	%	%	%	%	%	%
1860	29·9	11·6	58·5	16 1	68·6	15 3
1870	34 4	13 0	52·6	24 0	56·8	18·6
1880	32·7	21·3	46·0	55 8	29·4	14 8
1890.	33·2	22·8	44·0	42·2	36·6	20·2
1900.	27·2	33·1	39·7	39·8	24·8	35·4
1910.	21 0	37·1	41·9	21·6	33·6	44·8
1913.	22·4	35·8	41·8	20·7	30 5	48 8

The above table brings out very clearly the growth in the relative importance of industry in the United States during the fifty years before the war Among the imports, the relative importance of raw materials for industry increased threefold while the relative importance of manufactured articles declined by about one-third. On the export side the United States has tended more and more to export manufactures instead of raw materials of industry The high proportion of foodstuffs exported in the last quarter of the 19th century was mainly due to the rapid development of cereal cultivation. As the population and the standard of living steadily increased, the surplus available for export relatively declined, while at the same time the exports of manufactures increased.

(*c*) *France.*—Satisfactory figures of French trade first become available in 1815. Up to and including 1846 standard official unit values (fixed in 1826 and applied retrospectively to the recorded quantities for earlier years) were used, so that the figures represent the volume of trade rather than its real value. The following table gives the figures at decennial intervals throughout this period, together with the population.

	Imports for consumption	Domestic exports	Population
	Million £	Million £	Millions
1815	8·0	16·9	29·4
1825	10·0	21·8	31·4
1835	20·8	23·1	33·3
1845	34·2	33·9	35·2

Imports increased fourfold in the thirty years while exports doubled in volume. In the same period the population increased by about 20 per cent.

From 1847 onwards, the official unit values were revised annually, so that the figures more nearly represented actual values. The development of French trade subsequent to that date is shown in the following table.

Annual averages	Imports for home consumption	Exports of domestic produce	Population
	Million £	Million £	Millions
1850-4	40·3	51·5	35·9
1855–9	69·3	75·8	36·3
1860-4	91·9	90·1	37·4
1865-9	119·3	119·7	38·2
1870–4	136·5	135·4	36·7
1875-9	150·7	138·4	37·0
1880-4	190·0	138·5	37·7
1885-9	160·0	132·3	38·3
1890-4	168·8	136·8	38·4
1895-9	163·7	144·3	38·6
1900–4	182·1	168·6	39·1
1905–9	228·1	212·0	39·3
1910–3	318·9	259·0	39·6

Up till the Franco-Prussian War the value of imports was about equal to that of exports but thereafter the value of imports was consistently the higher Imports increased rapidly in value up to 1880–4 and exports up to 1870–4. There followed a distinct check till the end of the century. This check was mainly due to the heavy fall in prices. In France prices fell by rather over 40% between 1874 and 1896 when the lowest point was reached, while between 1896 and 1913 they increased by about 40 per cent With rising prices, the value of imports practically doubled between 1895–9 and 1910–3 while the value of exports increased by 80 per cent.

The growth in population has been small in France. In 1825 imports and exports amounted to about 25/- per head; in 1850–4 the figure had about doubled and by 1870–4 it had increased to about £7.10s per head. There was then little increase till the end of the nineteenth century, but by 1910–13 imports and exports had grown to nearly £15 per head

The distribution of imports and exports according to the principal classes of goods is shown in the following table, at decennial and other intervals from 1850

Year	Imports			Exports		
	Food	Raw materials	Manufactures	Food	Raw materials	Manufactures
	%	%	%	%	%	%
1850.	16·6	78·2	5·2	30·1		69·9
1860.	20·8	76·1	3·1	37·3		62·7
1869.	22·4	68·9	8·7	46·7		53·3
1880	39·0	49·1	11·9	23·4	23·5	53·1
1890	32·6	53·5	13·9	22·8	23·9	53·3
1900.	17·4	64·6	18·0	18·7	26·4	54·9
1910	19·7	60·6	19·7	13·8	31·0	55·2
1913.	21·6	58·7	19·7	12·2	27·0	60·8

(*d*) *Germany.*—It is only a hundred years ago that the first attempt was made at a co-ordinated commercial policy between the many independent states, large and small, which were to form in 1871 the German empire. The formation of the customs union between Prussia and certain North German States and between Bavaria and Württemberg in 1828 was followed in 1834 by the amalgamation of the two unions and thereafter other states gradually came into the Zollverein. Before 1871, a bird's-eye view of the rate of development of Germany's oversea trade may best be gained from the shipping statistics of the port of Hamburg. The following table shows the number and tonnage of vessels entering Hamburg at decennial intervals from 1791 to 1871:

Year	Number	Tonnage
1791	1,504	
1801	2,177	
1811	(Blockade)	
1821	2,008	161,066
1831	2,347	223,443
1841	3,194	371,804
1851	4,169	558,403
1861	5,219	992,419
1871	5,439	1,887,505

Progress was fairly slow in the period up to 1831, but thereafter the tonnage entering Hamburg increased at a rapid rate down to 1871 Forty years later, in 1911, the tonnage had increased to over thirteen million

From 1872, the trade of the Zollverein practically represents the trade of the empire The following table shows the development of this trade, together with the population from 1872 to the outbreak of the World War

Annual average	Imports for consumption	Domestic exports	Population
	Million £	Million £	Millions
1872–4	*	113·7	41·3
1875–9	*	132·3	43·1
1880–4	151·8	152·8	45·2
1885–9	159·9	151·0	47·3
1890–4	198·9	152·5	50·5
1895–9	232·8	181·3	53·8
1900–4	287·0	235·6	58·0
1905–9	304·3	314·0	62·2
1910–3	492·9	425·7	66·0

*Comparable figures not available

The general trend of both imports and exports was similar to that of the trade of the United Kingdom and France; a period of hesitancy in the last quarter of the nineteenth century, mainly due to the fall in prices, was followed by a period of rapid expansion of the value of trade in the early years of the present century, when prices were rising In the 'eighties the values of imports and exports about balanced and thereafter the value of imports was distinctly higher than that of exports. Imports and exports together were about £6.15s. per head of population in 1880–4, about £7.15s. in 1895–9 and by 1910–3 had risen to nearly £14 per head

Turning to the classes of goods imported, the following table shows the percentages of imports and of exports, classified as articles of food, raw materials, and manufactures.

	Imports			Exports		
	Food	Raw materials	Manufactures	Food	Raw materials	Manufactures
	%	%	%	%	%	%
1880	32·6	39·6	27·8	22·1	20·2	57·7
1890	33·5	42·0	23·6	14·2	21·3	64·5
1900.	30·6	48·6	20·8	11·2	24·1	64·7
1910	27·6	52·2	20·2	10·0	23·4	66·6
1913.	27·8	52·2	20·0	10·1	23·8	66·1

Such changes as occurred mostly took place before the end of the 19th century. The growth in imports of raw materials of industry is the most significant feature on the import side. Among exports, it will be seen that foodstuffs have decreased in importance, while raw materials and manufactures have increased. It

should be mentioned that the term "raw materials" in the German statistics includes considerable quantities of goods in a semi-manufactured state (*e g.*, pig-iron, steel, ingots, etc).

3. The World's Trade 1860–1913.—In the preceding section, the progress of the external trade of the United Kingdom, the United States, France and Germany has been traced throughout the 19th century and up to the outbreak of the World War. The earliest authoritative figures of the value of the trade of the world as a whole go back to 1867–8 and are given (up to 1894) in Dr. Neumann-Spallart's *Übersichten der Weltwirtschaft* and, for the later years up to 1908, in Otto Hubner's *Geographisch-Statistische Tabellen* The following figures (converted into sterling at 20 marks to the £) are taken from these publications. Imports and exports have been added together so that the value of the goods actually passing in the trade is about half the figures shown The figures for 1860 and 1865 are rough estimates.

Annual averages	£ millions	Sauerbeck's price index (1867–77 = 100)
1860	1,450	99
1865	1,750	101
1869 70	2,317	97
1872–3	2,888	110
1874/5–9	2,822	93
1880–4	3,283	83
1885–9	3,142	70
1890–4	3,508	69
1895–9	3,901	63
1900–4	4,791	71
1905–8	6,106	75

These figures cover the trade of some 75 to 100 countries; the additions to the number of countries in later years do not seriously affect the table, because the trade of the new countries, when first included, was relatively small in value.

The gold value of the world's trade appears to have about doubled between 1860 and 1872–3, but part of this increase was due to rising prices From 1872–3 till about 1895, when prices fell heavily, the gold value of the world's trade increased but slowly. Prices then rose again slowly till 1913, and the value of the world's trade rapidly increased.

It is of interest to compare the value of the trade of the four principal countries considered above with that of the value of the world's trade For the year 1880, Dr. Neumann-Spallart's tables show the value of the trade (imports and exports together) of these four countries to be just over 50 per cent of the world's total. Now, in considering alone the trade of these four countries, only those goods which pass *inter se* are duplicated in the total, while in the world total all goods are duplicated Making the necessary adjustments for this duplication, it may be estimated that in 1880 about 75 per cent, by value, of the goods passing in the trade of the world was imported into or exported from those four countries

The following table shows the values of the imports into and exports from the principal countries of the world and each continent at ten-yearly intervals between 1874–5 and 1905 according to the above authorities Figures for 1913, taken from the League of Nations publications and not comparable in all respects with the earlier figures, have been added

Between 1874–5 and 1905, the gold value of the world's trade rather more than doubled and, allowing for the fall in prices, its volume probably about trebled The trade of the United Kingdom and of France increased more slowly than the world's total trade, while that of Germany and the United States increased more rapidly Among other European countries, the trade of the Western countries shown increased far more rapidly than that of the Eastern countries. In other parts of the world, remarkable rates of increase are shown by Japan and Argentina. Considering the proportions of the total attributable to each continent, Europe's share fell from 72 per cent. of the total in 1874–5 to 64 per cent. in 1905 and (according to the League of Nations figures) to 61 per cent. in 1913. On the other hand, the share of America increased from 15 per cent. of the total in 1874–5 to

Figures in million £

*The United Kingdom figures for 1874–5 relate to total imports and total exports, those for 1885–1905, to total imports and domestic exports, and those for 1913 to retained imports and domestic exports.
†British N. America prior to 1905
**British E. Indies prior to 1895

19 per cent. in 1905 and to 21 per cent in 1913, the share of Asia also increased from 8 per cent of the total in 1874–5 to 11 per cent in 1905 and 1913

4. The Progress of Trade Since the World War.—The war completely upset the normal commercial interchange of commodities between the nations and the unsettled conditions prevailing immediately after the war—sharp variations in the value of money, depreciated exchanges, changes of frontiers, etc — render aggregate figures up to the end of 1923 of little value The following paragraphs are therefore devoted to a study of the world's trade in the years 1913 and 1924–7.

In making comparisons based on 1913, there are several factors of which account must be taken. Firstly, 1913 was a year of excellent trade—the crest of the wave following the trough of 1908. Secondly, prices have increased substantially since 1913; according to estimates made by the League of Nations, average gold values of world imports and exports were in 1924 about 50 per cent. above the 1913 level, in 1925 about 55 per cent. and in 1926 about 45 per cent Thirdly, the multiplication of frontiers resulting from the war, particularly in Europe, has the effect of swelling the recorded value of a given volume of trade, because much trade that was formerly internal became external, probably the recorded value of the world's trade has been increased by about 5 per cent owing to this cause.

The following table shows, in gold pounds, the value of the world's trade (imports for consumption and domestic exports) in 1913 and in 1924–6 The figures are taken from the League of Nations' "Memorandum on International Trade and Balances of Payments" and have been converted from dollars at $4 867 to the £.

Million gold £			
	Imports	Exports	Total
1913	4,009	3,772	7,781
1924	5,769	5,586	11,355
1925	6,609	6,310	12,919
1926	6,403	6,013	12,416
1927	6,669	6,234	12,9[illegible]3

The difference in the total figure for 1913 from that previously quoted is due to the exclusion of the trade of the Netherlands in the present table, owing to the pre-war figures not being comparable with the post-war figures. Making allowances for the changes in prices and multiplication of frontiers, it appears prob-

able that, in 1924, the volume of the world's trade was about 7½% smaller than in 1913, that in 1925 it had increased to slightly above the 1913 volume and that in 1926 it further increased to about 5% above the 1913 volume. The figures of value for the year 1927 are about 4% greater than those for 1926, and, making allowance for changes in prices the increase in volume was probably somewhat greater.

While, on the average of the years 1924–6, the volume of the world's trade was about as great as in 1913, there has been a marked change in the relative importance of the continents and principal countries. The share of Europe has sharply declined, while those of America and Asia have increased considerably. As already seen, a similar movement, due to the resources of the world being opened up, was taking place gradually before the war. The following table, taken from the League of Nations' "Memorandum," shows the percentage distribution of the world's trade by continents in 1913 and 1924–6.

Continent	Percentage share of imports and exports			
	1913	1924	1925	1926
Europe*	58 5	50 4	49 5	47·9
America	22·3	26·7	26·6	27·4
Asia	12·3	15·5	16·4	17·1
Africa	4·3	4 2	4·3	4·4
Australasia	2·6	3 2	3·2	3·2
World total	100 0	100 0	100·0	100 0

*Excluding the Netherlands, owing to the 1913 figures not being comparable with those of post-war years

The increased share of America is almost entirely attributable to the great increase in the trade of the United States, while that of Asia was mainly attributable to Japan and British Malaya. The fall in Europe's share of the total is mainly attributable to eastern and central Europe, though western Europe's share of the total also decreased somewhat

Special Trade in Merchandise
(Imports+Exports in Million gold £)

Country	1913	1924	1925	1926	1927
United Kingdom*	1,186	1,759	1,925	1,765	1,805
Germany*‡	1,021	765	1,034	967	1,192

India	279	397	464	415	429
Japan	143	354	396	414	401

*Changes of customs frontier have considerably affected the trade of these countries since 1913.
†Owing to changes in statistical method, the figures for post-war years are not comparable with those for 1913
‡Excluding reparation deliveries.

World Trade in Manufactures.—The World War stimulated the development of manufactures in most countries of the world because of the difficulty of obtaining the usual supplies of manufactures from the principal manufacturing countries. It is, therefore, of interest to ascertain whether, after the war, the trade in manufactured goods has become relatively less important than it was in 1913. Owing to the different classifications of goods adopted by the various countries this is a difficult task, but the British Board of Trade has made an estimate of the world's exports of manufactures (as defined in the Brussels International Convention classification) in respect of the years 1913, 1924 and 1925. The general results obtained were that in 1913 about 35% of the world's exports of merchandise consisted of manufactures, in 1924 about 36% and in 1925 about 35½%. Thus what slight change there has been appears to be in the direction of a comparative increase in the trade in manufactures. Such an increase may be due to prices of manufactured goods having risen relatively more since 1913 than those of foodstuffs and raw materials

Share of Various Countries in the World's Exports of Manufactures

Countries	Percentage of World Total		
	1913	1924	1925
United Kingdom*	28·0	26 6	25·5
United States	11·2	14 8	15 4

Austria, Hungary, Czechoslovakia and Yugoslavia*	3·3	5 5	5·2
Italy*	2·6	3 7	3·9
Japan	1·9	3·7	4·0
Belgium*	4·1	3·4	3 4
Switzerland	2 9	3 1	2 9
Canada	1 3	2 7	2 7
India	2·5	2 4	2 7
Netherlands	2 6	2 1	2 3
All other countries	4 7	6 2	6 4
World total	100 0	100 0	100 0

*Considerable changes of customs frontier affect these countries.

In 1913 the first four countries accounted for about three-quarters of the world's exports of manufactures, and in 1924 and 1925 for about two-thirds Germany's share decreased substantially, while that of the United States increased. Among other countries, the most significant features are the increased shares of Japan and Canada. The increased share of Austria-Hungary and the Succession States is more apparent than real, owing to the additional frontiers created between these territories. (*See* also MANUFACTURES, COMMERCE IN)

TRADE BOARD, a term applied in Great Britain to one of a system of industrial wages boards established to fix legal minimum rates of payment for workers in certain industries under the Trade Boards Acts of 1909 and 1918.

The principal Trade Boards Act of 1909 was based on the minimum wage provisions contained in the Factory and Shops Act of Victoria, Australia, passed in 1896. The Trade Boards Act was the result of long and vigorous agitation for legal protection on behalf of the "sweated" women workers, particularly in the chain making industry centred in Cradley Heath, and in the clothing trades of London and the great towns. Boards were first established in four trades set out in the act, namely, ready-made and wholesale bespoke tailoring; paper-box making; machine-made lace finishing and chain making. Before 1914 five new trades were added, making nine in all.

Each of these boards was composed of an equal number of representatives of employers and workers in the trade plus from one to three neutral persons, called "appointed" members designated to sit on each board in order that a deadlock might be avoided.

The bodies so constructed had two powers under the Act of 1909: 1. A mandatory power to fix minimum rates of wages for time workers in the specified trades; 2. A discretionary power to

fix general minimum rates of wages for piece workers in a trade. Rates of both kinds were subject to confirmation by the Board of Trade before becoming effective, and even then had to undergo the test of a six months' limited operation before they became obligatory upon all employers.

The action of these early boards was very cautious and in general their effect upon wages of women workers was to raise the general level of rates to that of the firms which were already paying the highest or very nearly the highest in the trade. Rates fixed for men, on the other hand, fell, on the average, below the rate for all men in a trade though they were higher than rates for the average unskilled man

Between 1912 and the signing of the Armistice in 1918 the principle of state wage regulation became widely recognised through extended legislation in Australia, the United States and Great Britain The tendency of the early months of the war in England was to favour suspension of Trade Board activities, but that attitude was soon abandoned in the interests of efficiency Then, in addition to the Coal Mines (minimum wage) Act passed in 1912, came the Munitions of War Acts of 1915, 1916 and 1917, the Corn Production Act of 1917 and finally the Wages (Temporary Regulation) Act of 1918, each of which provided for state control of wages in some form and thus strengthened the Trade Board idea

In line with the general movement towards state control and self-government in industry the second Whitley Report in 1918 recommended to Parliament the extension of the Trade Boards system to unorganised and spasmodically organised trades as a complement to the establishment of voluntary "Whitley" Councils in the better organised industries It was hoped that eventually organisation of both employers and workers in Trade Board trades would become strong enough to warrant their removal from Government surveillance to the category of Whitley Council industries, governed by a body of representatives of organised employers and workers co-operating voluntarily together for the good of the whole industry.

The background for the new Trade Boards Act which became effective on October 1, 1918, therefore, was threefold—first, more general acceptance of the principle of state regulation of wages; second, articulation of the democratic ideal of self-government in industry set in motion by the war; third, the foresight of those who realised that the aftermath of war would be a sharp drop in wages especially for unprotected workers, unless some machinery were provided to meet the exigency.

The Act of 1918 was thus born in an entirely new set of economic circumstances and was the result of a quite different concept from that of 1909 It consequently made several important changes in the Act of 1909. First, the situation conditioning establishment of a Trade Board was altered, emphasis being thrown upon inadequate organisation of workers or employers in a trade instead of relatively low wages; second, the rate fixing powers of boards were considerably enlarged; third, the responsibility of the Minister of Labour, who since 1917 had acted in place of the President of the Board of Trade, was increased and the onus of establishing boards was placed upon him rather than upon Parliament

By 1921 a total of sixty-three Trade Boards covering 39 trades and governing the wages of approximately 3,000,000 workers in the United Kingdom had been set up Of these boards nineteen, being established for Irish industries, now fall under the control of the Irish Free State, one is inoperative and one new board has been set up since 1921, making 44 boards active in Great Britain in 1928.

The Trade Boards System as it now stands is bi-partite. Legislative, that is rate-fixing power, is vested in the board set up for each trade, while administrative and executive functions rest with the Ministry of Labour and in practice involve four distinct features: 1. Setting up of boards; 2. Confirmation or rejection of rates decided upon by the Trade Boards; 3. Enforcement of legal rates; 4. Decision in matters relating to the demarcation between boards and their spheres of activity

The general composition of a Trade Board remains the same under the Act of 1918 as that of 1909. The underlying principle is that of representation and it falls to the Minister of Labour to discover the component parts of each industry, to assign appropriate weight to each and to find acceptable persons to represent each interest, so that the board as a whole can represent the trade in entirety and work in harmony. It is customary for the Minister to consult the various organised sections of a trade concerning these appointments and also to name persons who can express the point of view of such unorganised sections of the trade as there may be. The "appointed" members are usually chosen from among the professional classes such as professors, lawyers, social workers, etc. It is provided by statute that where a considerable body of women are engaged in the trade at least one of the appointed members must be a woman.

The Minister of Labour is empowered to make regulations with respect to the constitution and proceedings of Trade Board meetings including the method of voting, but apart from those rules which he chooses to lay down boards govern themselves.

Rates are arrived at by a process similar to bargaining assisted by the appointed members in the capacity of conciliators. Appointed members, however, have the power to vote just as other members of a board, but in practice this vote is seldom cast unless agreement between the two sides after negotiation becomes impossible and then it is done with reluctance.

As to the matter of what is a minimum wage, the Act of 1918 gives no more guidance than that of 1909, and experience shows that the two sides of a board as well as the appointed members usually hold divergent views as to the terms of their reference Employers probably most frequently interpret a minimum wage for a trade to be that already "payable to the lowest grade of worker in the least well equipped factory in the least expensive part of the country," while those on the workers' side stand for the current trade union rate in that or an allied trade as the minimum Appointed members, on the other hand, are most likely to construe the minimum in terms of their philosophy of what wages are and should be. In practice the failure of the Act to provide a more definite guiding principle works both for good and ill, on the one hand giving leeway for a broad construction of the purposes of the Act, and on the other, in certain cases making for confusion and too wide divergency in rates between trades When it comes to the bargaining co-incident to wage fixing in a board, workers generally press the argument of the "living wage" as a basis for negotiation, and employers adhere to "what the trade can bear." The result is almost invariably a compromise In this way the Trade Boards system enables the circumstances of each separate trade to be considered when the rate is fixed Each trade, moreover, is able to vary its own minimum rates at any time without waiting upon the remaining trades For an employer to pay wages below those fixed by a Trade Board is an injustice remedial by criminal law.

Abundant proof is available to show that in broad terms the three original objects of the Act of 1918 have, in some degree, at the least, been attained, *i.e* —

(1) To create instruments of self-government in poorly organised trades.

(2) To prevent a sudden fall in wages after the World War.

(3) To adjust wages upon a fair basis in future.

The chief defects in the system as shown by experience are:—

(1) The tendency for wage variations to take place too long after the conditions requiring change have arisen This is a fault in machinery easily remedied, and not serious except in time of rapid fluctuations in prices.

(2) Too little use of scientific investigation in comparison with "hearsay evidence" when rates are being set. This has been the cause of a large part of the mistakes made.

During the severe industrial depression of 1921 while European exchange rates were out of joint and wages remained relatively higher than prices, considerable opposition towards the Trade Boards system was evinced, and a Government investigation instituted. No important changes were made in the Act, however, though certain mistakes in wage rate fixing were voluntarily corrected as a result of experience

Since other economic conditions have somewhat settled down, therefore, the system seems to work smoothly and without undue adverse criticism, even though in some few instances boards have, as is measured by the level of the rates they fixed, gone slightly beyond what is considered the strict scope of minimum wage fixing and touched the fringe of the field of wage regulation.

(D. M. Se.)

United States.—In the United States the closest equivalent of the Trade Board is commonly known as a minimum wage commission. Acts creating minimum wage commissions for the purpose of fixing and enforcing minimum rates of wages have been held unconstitutional. (*See* Minimum Wage. *United States.*) Even in the case of the compulsory arbitration law of Kansas, because the board was given authority by the act to fix wages, the court held the act, to this extent, unconstitutional. The Minimum Wage Act of Massachusetts has been held constitutional in the Massachusetts courts but the decision was based on the fact that the act was not compulsory and that the rates of wages fixed by the board depended upon public opinion for their enforcement

In Massachusetts the board of conciliation and arbitration of the department of labour and industries devotes part of its time to the subject of minimum wages and while doing so is known as the minimum wage commission. The board is made up of three members, one of whom must be a representative of labour and one of employers of labour. The assistant commissioner of labour is given charge specifically of all matters relating to women and minors and is to exercise duties and authority in accordance with the directions of the commissioner with the approval of the minimum wage commission. The law provides that the commission shall investigate the wages paid to female employees in any occupation, if it has reason to believe that the wages paid to a substantial number of such employees are inadequate to supply the necessary cost of living and to maintain the worker in health. If after such investigation the commission is of the opinion that in the occupation in question the wages paid to a substantial number of female employees are inadequate to supply the necessary cost of living and to maintain the worker in health, it shall establish a wage board consisting of an equal number of representatives of employers in the occupation in question, and of persons to represent the female employees in that occupation, and of one or more disinterested persons appointed by it to represent the public, but the representatives of the public shall not exceed one half of the number of representatives of either of the other parties. The commission shall give notice to employers and employees in the occupation by publication or otherwise of its determination to establish a wage board and of the number of representatives of employers and of employees to be chosen therefor, and shall request that said employers and employees, respectively, nominate such representatives by furnishing names to it. The representatives of employers and employees shall be selected by the commission from names furnished by the employers and by the employees, respectively. The commission may transmit to each wage board all pertinent information in its possession relative to the wages paid in the occupation in question.

Each wage board shall take into consideration the needs of the employees, the financial condition of the occupation and the probable effect thereon of any increase in the minimum wages paid, and shall endeavour to determine the minimum wage, whether by time rate or piece rate, suitable for a female employee of ordinary ability in the occupation in question, or for any or all of the branches thereof, and also suitable minimum wages for learners and apprentices and for minors under eighteen. When a majority of the members of a wage board shall agree upon minimum wage determination, they shall report such determination to the commission, together with the reasons therefor and the facts relating thereto. Upon receipt of a report from a wage board, the commission shall review the same and may approve or disapprove any or all of the determinations recommended, or may recommit the subject to the same wage board or to a new one. The commission shall, after a public hearing, publish at such times and in such manner as it may deem advisable also at such times and in such manner as it shall deem advisable publish the facts, as it may find them to be, as to the acceptance of its recommendations by the employers engaged in the industry to which any of its recommendations relate, and may publish the names of employers whom it finds to be following or refusing to follow such recommendations

(E Ste.)

TRADE CYCLE. The phrases trade cycle, business cycle and cyclical fluctuation of trade are all convenient methods of labelling those alternating upward and downward sweeps in the volume of business activity which have constituted, for at least a century and perhaps more, one of the outstanding phenomena of the modern business world The most obvious manifestations of the trade cycle are a quasi-rhythmical fluctuation, extending over several years, in the level of prices, the level of money profits and the level of employment In the absence of satisfactory statistics, it is difficult to be sure how far there occurs a corresponding fluctuation in the level of production and consumption, *i e.*, in the real income of the community affected While it is certain that these latter quantities fluctuate to some extent, it seems probable (*a*) that the fluctuations in output are less intense than the fluctuations in prices, (*b*) that the output of ordinary goods for immediate consumption fluctuates as a rule far less than the output of instrumental or constructional goods (typified by iron and steel); and (*c*) that the fluctuations in output do not entirely synchronize with the fluctuations in prices, but that, in the later stages of a "boom" of prices, production may cease to make any significant advance, while in the later stages of a "depression" of prices production may make a marked recovery. Nor is it safe to dogmatize about the length of the trade cycle or about the degree to which its phases synchronize in the leading industries and the leading industrial countries Before the World War there were indications that the normal period of the cycle had shortened from about 10 to about six or seven years. The dates of "crisis" or turning-point from boom to depression, during the past century, are for England 1825, 1836, 1847, 1857, 1866, 1873, 1882, 1890, 1900, 1907, 1913, 1920, while in the United States the booms of the late '80s and '90s were prolonged, somewhat precariously, to 1893 and 1903 respectively. Again, the post-War boom, which in England and America broke in 1920, was prolonged in Germany till 1923, and while the recovery in America from the great slump of 1921 has been rapid and complete (with a slight set-back in 1923), recovery in England has been partial and slow. Again, the change-over from depression to prosperity, or prosperity to depression, does not affect all trades at the same moment, or even always in the same order In the main, however, it still seems to be fair to describe the trade cycle both as a *general* movement and as a rhythmical one, and any explanation of its causes must take these two factors into account Very many such explanations have been offered—too many to expand or criticise fairly in the course of a short article It must be enough to set out and classify certain roads of thought, as it were, along which economists have been led to travel in search of the truth.

The Psychological Approach.—The first road leads into the domain of psychology. We are invited to find the chief explanation of the trade cycle in the nature of man himself, and especially of those men who are responsible for conducting and controlling the operations of modern industry, commerce and finance. These business leaders are bound together not only by their business dealings but by ties of sentiment and environment: they operate, necessarily, in an atmosphere of uncertainty and any error of forecasting which they make, whether of an optimistic or of a pessimistic kind, is apt to be magnified by their mutual contact into a great wave of erroneous judgment, which gathers strength for a time and then breaks, yielding place to an equally exaggerated movement in the opposite direction There seems to be little doubt of the importance of this factor both in aggravating the amplitude of the trade cycle and in moulding it into its quasi-rhythmical shape. But we must be on our guard against supposing that all decisions made by business men to vary the scale of their purchases or their output are erroneous. Many such

if not of society as a whole.

The Monetary Approach.—The second road leads into the tangled wood of monetary theory. Those who follow it lay stress on the dependence of the scale of industrial activity on the general level of prices, and on the dependence of the latter, in its turn, on the monetary policy of the Government and the banks. The independent leaders of business are advantaged during a period of rising prices, because the rise in many of their money costs of production (such as debenture interest, salaries and in some degree wages) lags behind the rise in their money receipts. They are accordingly both enabled, and furnished with a real inducement, to expand the scale of their operations; and owing to their habit of concentrating their attention on the movement of the price of *their own products*, the inducement is likely to seem greater to them than it actually is Conversely, in time of falling prices, business men are both disadvantaged by the relative fixity of some of their money costs, and believe themselves to be more disadvantaged than they are; and they are impelled therefore to contract the scale of their operations. These price movements, if left unchecked, act *cumulatively*, in both directions; for as long as prices are expected to go on rising, business men continue to rush in to buy; and as long as prices are expected to go on falling, business men continue to liquidate their stocks of goods, and to refrain from replenishing them.

Now modern currency and banking systems, even when anchored to a gold standard, are of such a kind, that, unless consciously operated with another end in view, they permit considerable play to these price movements. Indeed they exaggerate them by displaying an excessive timidity in altering those rates of interest whose magnitude has an important effect in determining the volume of loans issued by the banks, and consequently the volume of purchasing power put, in the form of cheque currency, into the hands of the public. In the last resort, therefore, it is held, both the unhealthy activity and speculative excesses of the period of boom, and the wasteful stagnation of the period of depression, are due to a faulty loan-policy on the part of the banks, or a faulty currency policy on the part of the Government, or a combination of the two One objection to this explanation in its cruder forms is that the level of prices depends not only on the quantity of purchasing power issued to the public by the Government and the banks, but on the willingness of the public to *use* the purchasing power when it has got it; and that it does not seem certain that this latter factor, especially in a time of deep depression, when everybody is determined to hoard money rather than spend it, is entirely explicable in monetary terms or controllable by monetary means. Nevertheless, there seems little doubt that a monetary policy consciously aimed at keeping the general price level approximately stable, would do a good deal to damp down the violence of the trade cycle; and a policy of this kind has apparently been followed with some success by the Federal Reserve Board in the United States since 1922.

Instabilities Inherent in the Economic Process.—The third and fourth groups of roads lead to an examination of certain *real*, as opposed to merely monetary or psychological, features of modern industry. The third group runs through a landscape of *physical* and *technical* features, the fourth through a landscape of *legal* and *social* ones. Let us consider the former by asking the question: "What rational reasons are there why industry as a whole should automatically increase and diminish the scale of its output?" and glancing at three possible lines of reply:—

(1) Because of a self-renewing rhythm in its real costs of production. During the later stages of a depression, there is a progressive advance in the effectiveness of labour, a progressive writing off of inflated capital charges, a progressive overhauling of methods of technique and organization, which breed renewed activity. During the later stages of a boom there is a progressive recourse to inferior instruments of production, a progressive utilization of over-tired and recalcitrant labour, wasteful methods of management, and inferior business leadership, which ultimately breed collapse.

(2) Because of variations, due to fluctuations in the bounty of nature, in the amount of agricultural produce offered in exchange for the products of industry. Normally, the effect of good harvests is to stimulate industry and of bad harvests to depress it; but there seem to be exceptional cases (as perhaps in 1920) where an over-abundance of agricultural products leads to such a fall in their price as to impair seriously the purchasing power of agricultural producers over the products of industry, and so to induce industrial depression. Many attempts have been made to connect the trade cycle directly with a cycle of crop-yields dependent on meteorological phenomena: the most famous is that of Prof. W. S Jevons to connect the supposed ten-year period of the trade cycle with the sun-spot period, and the most recent that of Prof H. C. Moore to establish an eight-year period in economic affairs, depending on the behaviour of the planet Venus. Without accepting any such views, it is possible to hold that harvest variations, through their influence on the demand for transport and in other ways, frequently exercise an important influence in moulding the shape and the intensity of the trade cycle. It follows that the more numerous the sources of supply of any crop and the greater the facilities for carrying it over from year to year, the better for industrial stability; and it has been suggested in certain quarters that governmental purchase and storage of the leading crops would assist materially in the process of industrial stabilization

(3) Because of variations in the intensity of the desire for the fixed instruments of production and transport—buildings, machinery, railways, ships, etc. These instruments are large and expensive; they take a long time to construct, but once a batch of them is constructed, it will serve to satisfy the increased needs of the community for many years Investment in such instruments is therefore discontinuous, and their rate of output especially variable; and variations in the prosperity of the trades making them react severely on other trades. The rate of investment in instruments depends a good deal on the progress of technical invention, and it is tempting to connect a good many of the booms of the last century with inventions, *e g*, that in England in 1847 with railway-building, that of 1900 (especially in Germany) with electric transport, etc.

Instability Resulting from Organization of Industry.—We come finally to certain legal and social features of modern industry which may be held to promote instability of prices and output

(1) There is first the fact of *competition*, which aggravates miscalculation, since individual producers do not gauge correctly the share of an increased market which will fall to their own lot, nor the effect which their rivals' action will have in driving up their own costs of production It might be hoped, therefore, that the progress of the movement toward the formation of "trusts" and combines would damp down the violence of the trade cycle; but so far it is difficult to be sure that this hope has been fulfilled, partly because it is not always in the interest of combinations to promote stability, and partly because they are apt to interpret stability as stability of *prices*, which is not always consistent with stability of *output* and employment.

(2) There is secondly the *wage-system*, which may lead to a real disharmony between the interests of the employing class, which dictate the course of production, and those of society as a whole. For generally speaking the employer has more interest in intensifying production during a boom and curtailing it during a depression than the workman, who suffers during the boom from speeding-up and during the depression from unemployment.

(3) Finally, there is the *unequal distribution of wealth*, which in the view of many writers leads to a chronic tendency to "over-saving," manifesting itself during the boom in the construction of more instruments than will be able ultimately to find remunerative employment, and during the depression in, among other things, a piling up of idle bank-balances. The remedy proposed is to increase the purchasing power of the wage-earner, whose desire for necessaries and comforts is held to be steadier and more elastic than the desire of the rich for luxuries.

It remains to add that much work has been done in recent years, especially in America, in compiling statistical data con-

cerning the trade cycle, and attempting to forecast its course. The more accurate the forecasts can be made, and the more widely business men act upon them, the greater will be the extent to which the course of the trade cycle is smoothed and evened out under the influence of the forces of instructed self-interest.

TRADE FACILITIES. In Great Britain the trade facilities scheme formed part of the remedial measures laid before the House of Commons by the Coalition Government of the United Kingdom in the autumn of 1921. Prices were then at their lowest; trade was acutely depressed; and unemployment had reached an alarming figure. One of the factors retarding the recovery was the difficulty experienced in raising capital, and it was proposed to use the credit of the Government to overcome the obstacle. The Trade Facilities Act of 1921 empowered the Treasury to guarantee the principal and interest, or either the principal or interest, of loans for capital purposes. No loans could be made by the Treasury, but with the aid of the Government's credit the applicant would of course be able to borrow his requirements on exceptionally favourable terms. Under the original Act the aggregate amount to be guaranteed was fixed at £25,000,000, but by subsequent legislation the amount was added to from time to time. The Act of 1926 raised the total to £75,000,000 and extended the period of operation to March 31, 1927.

Results of the Scheme.—The extent to which advantage was taken of the scheme affords some indication of the stimulus which it gave to industry and to employment. The quarterly return issued for the period ending March 31, 1927, gave the total figure of guarantees approved by the Treasury, after deduction made on account of applications sanctioned but subsequently cancelled by the applicants, at £74,251,780. The greater part, in fact about two-thirds of the whole, was given for enterprises in Great Britain. A remarkable proportion went to the shipping industry, mainly for new shipbuilding. A considerable percentage was also allocated for railway development, the London underground group alone having obtained some £12,500,000 for improvements and extensions. Another prominent category was electrical propositions both at home and overseas. Unquestionably, therefore, the undertaking of many projects of diverse kinds was expedited.

A cognate scheme relating especially to imperial development and arising out of the discussions at the Imperial Economic Conference of 1923, was also embodied in the Trade Facilities Acts (Act of 1924). The Treasury was empowered, subject to certain terms and conditions, to make a contribution of an amount not exceeding three-quarters of the interest payable in the first five years of the currency of a loan raised in the United Kingdom by or on behalf of any public utility undertaking in any part of the Empire overseas. An important condition required that the expenditure should be in anticipation of expenditure which would normally have been incurred at a later date. The scheme had currency for three years from its commencement—*i.e.*, to May 14, 1927, and the maximum amount payable by the Treasury was not to exceed £5,000,000. Contributions sanctioned under this scheme, spread over periods of three to five years, were in round figures £148,000 to the Sudan Government in respect of two schemes for the purchase of railway materials; £29,000 to the government of Newfoundland for the same purpose; and £37,000 to Western Australia for the purchase of a new ship. (W. H. Cl.)

TRADE FORECASTS. The expressions "trade forecast," commonly used in Great Britain, and "business forecast," commonly used in the United States, are synonymous and, unless qualified, refer to the outlook for business as a whole in a given country in the immediate future for, say, a period of not more than a year or a year and a half. The terms "trade" and "business" are used in their broadest sense to include all branches of economic activity. General forecasts are, of course, frequently supplemented by specific forecasts for sections of a country and for industrial groups, individual commodities, security markets or money conditions.

The Typical Period.—A forecast begins properly with an appraisal of conditions at the time of forecast and follows with a prediction of the direction and magnitude of the movement during the immediate future. Such a forecast may include estimates of prospective variations expected to appear with the round of the seasons, and the "normal," or long-time, growth that is expected from one year to the next assuming no disturbing influences. But estimates of seasonal variation and the growth element are not usually the factors of primary importance in a business forecast. The factor of primary importance is the nature of the ensuing "cyclical" movement of business or of the "state trade."

A "business cycle" is at the basis of the great majority of business forecasts. (*See* TRADE CYCLE.) Some business forecasters contend that business cycles are "periodic"; in other words, they hold that an approximately uniform time interval exists between a given phase of each business cycle and the same phase in the succeeding cycle. They base their forecasts upon the assumption of a fixed period, but they are not all in agreement as to the length of it. Periods of ten, eight, seven, and three or four years have been held to exist by different investigators. In the United States, for example, between 1879 (when that country resumed specie payments) and the World War severe business disturbances—during which a period of high or expanding business was followed by a period of contracting business—occurred in 1882, 1887, 1890, 1893, 1895, 1899, 1903, 1907, 1910 and 1912. Some of these years of business disturbance were followed by deep business depression (1884–85, 1893–94, 1896–97 and 1908), others by more moderate depressions (1904 and 1911), and still others by periods of less pronounced business recession not ordinarily thought of as veritable depressions (1887–88, 1891 and 1900). Forecasters who base their forecasts upon the assumption of a "typical" cycle of standard form, amplitude and length (say 40 months, with 25 months of expanding business and 15 months of contracting business) are obliged, in practice, to depart from the rigidity of the concept in order, to make it consistent with history and to provide for the probability that future business cycles may prove to be as variable as those of the past.

Variations in Time.—A second group of forecasters finds it more in accordance with business history to drop the concept of a "typical" periodic cycle and substitute the concept of a business cycle of *variable* time, duration, amplitude (intensity of cyclical deviation from normal) and form (reflected by the steepness of the recovery from depression and ascent into prosperity and by the swiftness of the subsequent decline). If this concept be adopted, forecasts must be made on the basis of uniformities or regularities other than time-duration, amplitude, or form of the cyclical movements. Regularities have, in fact, been found in the sequence of the movements of various statistical series reflecting speculation, business and credit, a sequence which has been found to be much less subject to variation than the cycle itself. This sequence has been found in the United States, England, France and Germany and it affords a valuable means of forecasting the movements of series of one type from a knowledge of the movements of series of other types. Such forecasting requires a careful interpretation of the economic significance of the situation reflected by the various types of movements and hence the sequence itself is not a sufficient

means of forecasting In other words, a mechanical application of the sequence doctrine may not give satisfactory results. Particularly, the systematic regulation of credit by banking authorities, gold movements and other factors operating on the money markets must be considered.

Other Methods.—A third group of forecasters holds that (*a*) the alternation of business prosperity and depression and (*b*) the sequences between movements of individual statistical series are both so irregular that the concept of a business cycle should be discarded. In making business forecasts the members of this group rely upon general economic analyses of the current situation and evaluations of the movements which they find, at any time, to be in progress This group is, perhaps, less homogeneous than the others

A fourth group of forecasters rely upon mechanical statistical relationships (which can seldom be interpreted adequately in economic terms) as a basis for their predictions. For instance, forecasts have been made on the assumption that "action and reaction are equal and opposite" in business fluctuations as well as in mechanics Frequently, such forecasts are accompanied by general economic analyses that make them on their face indistinguishable from those of the third group

Development of Forecasting.—Business forecasting has received its greatest development in the United States and the description, just given, of methods of forecasting is based primarily on usage in that country. Systematic forecasting, however, is being developed in England, France, Japan and other countries. Forecasting is an outgrowth of statistical studies of business fluctuations rather than of the application of general theories of the causes of such fluctuations A condition for satisfactory business forecasting is the existence of adequate business statistics, promptly available at weekly or monthly intervals. This condition has been more fully met in the United States than in any other large commercial country.

Agencies Publishing Forecasts.—Various agencies in the United States and some in other countries publish more or less definite forecasts of general business conditions. Among such agencies in the United States are banks, journals, Government bureaux and commercial forecasting organizations. In other countries, forecasts are published by certain journals, but regular forecasting services have only recently been established outside the United States. There is such a service, however, in Japan A development has been the establishment of economic services under the auspices of Harvard university (Harvard Economic Society) in the United States, under the London School of Economics and Political Science and the Department of Economics of the University of Cambridge (London and Cambridge Economic Service) in England, under the Institute of Statistics of the University of Paris (Mouvement Général des Affaires en France et en Divers Pays) in France, and under the Institute of Statistics of the University of Padua and the Institute of Economic Statistics and Economic Politics of the University of Rome (Indici del Movimento Economico Italiano con Alcuni Confronti Internazionali) in Italy. These four services are associated

TRADE MARKS. A "trade mark" may be defined as a symbol, consisting in general of a picture, a label or a word or words, applied or attached to the goods of a trader for the purpose of distinguishing them from the similar goods of other traders, and of identifying them as his goods, or as those of his successors, in the business in which they are produced or put forward for sale. A trade mark differs in its legal character both from a patent and from a copyright. In the case of a trade mark the property and the right to protection are in the device or symbol adopted to designate the goods to be sold, and not in the article which is manufactured and sold The article is open to the whole world to manufacture and sell and all that the owner of the trade mark is entitled to prevent is such use of his mark by other traders as will lead purchasers to buy, as his, goods which are not his. On the other hand, patent-right and copyright protect the substance of the article, and any unauthorized manufacture of it in the former case, or reproduction of it in the latter, while the protection lasts, is prohibited. The grounds, however, on which trade marks, patent-right and copyright obtain legal recognition, though they are to a certain extent dissimilar, have a common element Patent-right and copyright rest upon the view that the results of the original labour of the inventor and the author ought, as a matter alike of justice and of public policy, to be secured against piracy; while, as regards the proprietor of a trade mark, the question of originality does not arise so long as the mark is sufficiently distinctive really to identify his goods and, for purposes of registration, to satisfy the Trade Marks Acts In truth, the registration of a trade mark is rather the recognition of a fact than the grant of a privilege (Kerly and Underhay, *Trade Marks Act*, 1905, p. 3).

The law as to trade marks as well as that as to patents or copyright is based on a man's rights to have guaranteed to him the profit derivable from his own property

British Trade Marks Before the Registration Acts.—English trade-mark law practically commences with the first years of the 19th century. The use of trade marks was indeed of far earlier date, for in 1742 we find Lord Hardwicke declaring that "every particular trader had some particular mark or stamp" But in the very case in which Lord Hardwicke made that statement (*Blanchard* v *Hill*, 2 Atkyns, 484) he refused to protect the "Great Mogul" stamp on cards, being apparently under the influence of the notion that the legal recognition of trade marks would involve the creation of a new species of monopoly But although the actual law of trade marks cannot be traced farther back than the beginning of the 19th century, Lord Eldon repeatedly granted injunctions to restrain one trader from fraudulently "passing off" his goods as those of another, and thus laid a foundation on which the present law has been built up. It was decided by Lord Cottenham in 1838, in the leading case of *Millington* v. *Fox* (3 Mylne and Craig 338), that an injunction to restrain the infringement of a trade mark could be obtained, even although the defendant had acted without fraudulent intent. On the common law side, on the other hand, fraud was an essential ingredient in the cause of action, and remained so till the fusion of law and equity by the Judicature Acts

The effect of Lord Cottenham's decision in the case of *Millington* v. *Fox* clearly was to recognize a right of property in trade marks, and the action for infringement became a familiar species of litigation. Under the then existing law, however, the plaintiff in such actions generally found himself in a very disadvantageous and unsatisfactory position. The basis of his action was the reputed association between his trade mark and his goods. This association the defendant—often a person of no means—would deny, and it had to be proved as a fact by witnesses at a cost to the plaintiff which there was little hope of his recovering. Moreover, even if the trade mark proprietor secured a judgment in his favour, it carried with it no immunity from the obligation of again establishing his right to the mark against any subsequent infringer who chose to dispute it. To complete this statement of the shortcomings of the law before the Merchandise Marks Act, 1862, it should be noted that the infringement of trade marks—except in cases where the seller of spuriously marked goods cheated the buyer—was not a criminal offence.

Under the Registration Acts.—Provision was first made for the registration of trade marks by the Trade Marks Registration

Act, 1875. This act was a considerable success, but no provision was made under it for the registration of words unless they either were old marks or were registered in combination with one or more of the "essential particulars" prescribed by the act, such as a distinctive device, heading, mark, label or ticket. These limitations excluded from registration most of the trade marks ordinarily in use.

The Patents, Designs and Trade Marks Act, 1883, remedied this defect besides altering the law in other important respects. The act of 1883 was amended in 1888 on the recommendation of a committee presided over by Lord Herschell. Neither the act of 1875 nor those of 1883 and 1888 altered the common law definition of a trade mark, nor contained any definition of the term. The description in the acts of what was registrable as a trade mark led to much litigation, and the interpretations of the judges left commercial men dissatisfied on three points: (1) The number of good and valuable trade marks which were not registrable; (2) that on allowing registration the Patent Office insisted on disclaimers which hampered the owner in obtaining protection in the Colonies and foreign countries; (3) that there was no effective period of limitation to attacks on registered trade marks, because, though registration for five years was declared conclusive by sec. 76 of the act of 1883, the powers of the court to rectify the register could be invoked even after the lapse of the five years (*re Gestetner's Trade Mark*, 1907, 2 Ch. 478). In re-enacting and enlarging the provisions of the act of 1875 the act of 1883 laid down certain essential particulars of one at least whereof a trade mark must consist to be registrable. The act of 1883 first provided for "word marks," and included among them "a fancy word or words not in common use" (sec. 64 [1] [c]).

The expression "fancy word," used in the act of 1883, gave rise to considerable difference of opinion. It was interpreted by the court of appeal as equivalent to "obviously meaningless as applied to the article in question," or "obviously non-descriptive" In accordance with this interpretation, the words "gem" for guns, "melrose" for a hair restorer, "electric" for velveteen, and "washerine" for a soap were all held not to be registrable. On the recommendation, however, in 1887, of a committee appointed by the Board of Trade, and presided over by Lord Herschell, the expression "invented word" was substituted for "fancy word" by the act of 1888

In 1905, 1907, 1914 and 1919 the statute law as to trade marks was amended and remodelled A bill was introduced in 1905 at the instance of the London Chamber of Commerce, and after consideration by a select committee became the Trade Marks Act, 1905. This act repeals the bulk of the provisions of the Patents, etc., Acts of 1883 and 1888 with respect to trade marks, and embodies them with amendments in a separate statute.

The Act of 1905.—This differs from the preceding acts in containing a definition of trade mark for the purposes of the act unless the context otherwise requires; viz., that it "shall mean a mark used or proposed to be used upon *or in connection* with goods for the purpose of indicating that they are the goods of the proprietor of such mark by virtue of manufacture, selection, certification, dealing with or offering for sale"; and "mark" is defined as *including* "a device, brand, heading, label, name, signature, word, letter, numeral or any combination thereof" (sec. 3). The act, modifying to the extent indicated in italics the acts of 1883 and 1888, prescribes (sec. 9) that a trade mark to be registrable must contain or consist of at least one of the following essential particulars:

1 The name of a *company*, individual or firm represented in a *special* or particular manner (under the act of 1883 it has been held that the name must be in the nominative case, and that ordinary printing is not representation in a particular manner).

2. The signature of the applicant for registration or some predecessor in his business. It is not clear that this includes descriptive trading styles.

3. An invented word or words.

4. A word or words having no *direct* reference to the character or quality of the goods, and not being *according to its ordinary signification* a geographical name *or a surname*.

5. *Any other distinctive mark; but a name, signature, or word or words other than such as fall within the descriptions in the above paragraphs 1, 2, 3 and 4, shall not, except by order of the Board of Trade or of the court, be deemed a distinctive mark.* By distinctive, is meant "adapted to distinguish in Great Britain, not in foreign markets (*In re Gallahero Application*, 1924, 41 T.L.R. 139) the goods of the proprietor of the trade mark from those of other persons": and "in determining whether a trade mark is so adapted the tribunal may in the case of a trade mark in actual use take into consideration the extent to which such user has rendered such trade mark in fact distinctive for the goods in respect of which it is registered or proposed to be registered." Where the mark is limited to specified colours, that fact may be taken into account in deciding whether the mark is distinctive (sec 10)

Trade marks containing the essential particulars are not registrable if they contain any matter which would by reason of its being calculated to deceive or otherwise be disentitled to protection in a court of justice or would be contrary to law or morality, or any scandalous design (sec. 11).

Old marks are registrable, *i e.*, any special or distinctive word or words, letter, numeral or combination of letters or numerals, used by the applicant or his predecessors in business before Aug. 14, 1875 (sec. 9). In the case of new marks, but not of old marks, a trade mark is not registrable except by order of the court in respect of any goods or description of goods which is identical with a mark already on the register with respect to such goods or description of goods, or so nearly resembles such registered mark as to be calculated to deceive (sec. 19). The expression "calculated to deceive" has been considered by the courts in very many cases. It is not merely or chiefly the retailer or dealer who has to be kept in view when the question of the likelihood of deception is under consideration. The courts have regard also, and mainly, to the ultimate purchaser whom the trade mark may reach, and careless or unwary persons are considered as well as those who are careful and intelligent. The judge's eye is the ultimate test as to the degree of resemblance that is calculated to deceive, although expert evidence on the point is admissible. The following words have been held to give rise to a probability of deception and confusion. "Oxot" with "Oxo" (meat extract: *Oxo, Ltd.* v. *King*, 34 R.P.C. 135); "Nuvol" with "Nujol" (heating or lubricating oils: *In re McDowell's Application*, 1926, 43 R P.C. 313); "Angora" with "Onsoria" (hair cream: *Lewis* v. *Vine and Vine's Perfumery Co.*, 31 R P C 12), "Peps" with "Pan-Pep" (cough pastilles: *In re United Chemists Association's Trade Mark*, 1923, 40 R.P.C. 219); "Anchola" with "Anchovette" (fish pastes and potted meats: *In re Waide and Co.'s Application*, 33 R.P.C 320); "Limit" and "Summit" (shirts and collars: *In re Smith* [Thomas A.], *Ltd.'s Application*, 30 R P.C. 363); "Lavnoma" with "Lavona" or "Lovona" (toilet preparations: *Tokalon, Ltd.* v. *Davidson and Co.*, 32 R.P.C. 133).

Invented Words.—An invented word need not be wholly meaningless, nor is it disqualified because words may have suggested it. Thus "mazawattee" was held to be an "invented word," although the latter part of it was a Sinhalese term meaning "estate," and there were estates in Ceylon (*In re Densham's Trade Mark*, 1895, 2 Ch. 176), having names ending with "wattee" from which tea came; and in a leading case on the construction of the clauses under consideration (*Eastman Co.'s Trade Mark*, 1898, A.C. 571), the word "solio" was held to be registrable as a trade mark for photographic printing paper under both clauses, although it was objected that "solio" was equivalent to "sunio." "Savonol" for soap (*J. C. and J. Field, Ltd.* v. *Wagel Syndicate. Ltd.*, 1900, 17 R.P.C. 266), "tachytype" for typographical and composing machines (*In re Linotype Co.'s Application*, 1900, 17 R.P.C. 380), have been held to be invented words. But the following have been held not invented: "uneeda" (=you need a), *In re National Biscuit Co.* (1902; 1 Ch. 783); "absorbine" for an absorbent preparation (*Christy and Co.* v. *Tipper and Son*, 1905, 21 R.P C. 97, 775); "bioscope" (*Warwick Trading Co.* v *Urban*, 1904, 21 R.P.C. 240); "cyclostyle" (*Re Gestetner's Trade Mark*, 1907, 2 Ch. 478); and *cf In re Kodak and Trade Marks*,

1903, 20 R.P.C. 337; "lactobacilline" for a lactic ferment (*In re La Société Le Ferment's Application* [1912], 81 L.J., Ch. 724).

Identical marks (except old marks) may not be registered in respect of the same goods, or goods of the same description, for two different persons (sec. 19); and where several applicants make rival claims to identical marks the registrar may refuse to register until their rights have been determined by the court or settled by agreement in manner approved by the registrar, or, on appeal, by the Board of Trade (sec. 20). In the case of honest concurrent user or of other special circumstances making it proper so to do, the court (or registrar: act of 1919, sec. 12, sched. 2), may permit the registration of the same mark or of nearly identical marks for the same goods by more than one owner, subject to such conditions or limitations, if any, as to mode or place of use or otherwise as the court (or registrar) may think it right to impose (sec. 21).

New provisions were made in 1905 as to what are called "associated trade marks" Where registration is sought for a mark so closely resembling a mark of the applicant already on the register for the same goods as to be calculated to deceive or cause confusion if used by any one but the applicant, the registration of the new mark may be conditional on entering both marks as associated trade marks (sec. 24).

In the case of combined trade marks provision is made for registering as separate trade marks the part in which the applicant has exclusive rights, and as associated marks trade marks of which the exclusive portion forms a part (sec. 25).

A series of trade marks of the same owner may be registered on one registration as associated marks (sec. 26).

Provision is made for allowing the registration of marks used upon or in connection with goods by an association (or person) which undertakes the examination of goods in respect of origin, material, mode of manufacture, quality, accuracy or other characteristic, and certifies the result of the examination by marks used upon or in connection with the goods. These marks cannot be registered unless the Board of Trade consider their registration of public advantage. Their registration is not conditional on the association or person being a trader or having goodwill in connection with the examination or certification. The registration gives the association or person the rights of the owner of a registered trade mark, except that assignment and transmission needs permission of the Board of Trade (sec. 62).

In respect of cotton piece-goods, marks consisting of a line heading alone or a word alone are not registrable, and no word or line heading is treated as distinctive in respect of such goods. In respect of cotton yarn the same rule applies with respect to words, and no registration of any cotton mark (in respect of cotton piece goods or cotton yarn: Trade Marks Act, 1914, sec. 1) gives any exclusive right to the use of a word, letter, numeral, line, heading or combination thereof (sec. 64 [10]).

By sec. 68, which is a re-enactment of sec. 105 of the Patent, etc., Act, 1883, it is made illegal for any person without the authority of the King to use the royal arms in any trade in such a manner as to create the belief that he has authority so to do.

Registries.—The central register of trade marks is kept at the Patent Office, Southampton buildings, London, and is under the charge of the comptroller-general of patents, designs and trade marks, who is appointed by, and acts under the superintendence of, the Board of Trade, and has a deputy—the registrar of trade marks. There is a branch registry at Manchester, whose chief officer is the keeper of cotton marks, which deals with all applications for the registration of trade marks for cotton goods falling within classes 23, 24, 25 in sched. 3 of the Trade Marks Rules, 1906.

There is a branch at Sheffield containing the marks for metal goods ("Sheffield marks") registered by persons carrying on business in or within 6 m. of Hallamshire. The care of this register is vested in the Cutlers' company, who are substituted for the comptroller as to registration of "Sheffield marks" (sec. 63). Applications made to the company are notified to the registrar, and may not be proceeded with if he objects. Any person aggrieved by the registrar's objection may appeal to the court. Applications made to the registrar for metal marks are notified to the Cutlers' company. Persons aggrieved by the decision of the Cutlers' company have an appeal to the courts (sec. 64).

A trade mark must be registered in respect of particular goods or classes of goods (sec. 8). The procedure for obtaining registration is regulated by the acts of 1905–19 and the statutory rules made thereunder (March 9, 1920, and Sept. 29, 1925). The registrar has power to refuse applications or accept them absolutely or subject to conditions, amendments and modifications (sec. 12). His discretion is not absolute, but subject to the provisions of the act (*Re Birmingham Small Arms Co.'s Application*, 1907, 2 Ch. 396), and must not be unreasonable or capricious (*Eno* v. *Dunn*, 1890, 15 A.C. 252; *Registrar of T.M.* v. *W. and G. Du Cros, Ltd.*, 1913, A.C. 624; *In re Garrett*, 1916, 1 Ch. 436). He must, if required, state his reasons, and his decision is subject to appeal to the Board of Trade or the court at the option of the applicant (sec. 12 [3]).

"New marks" may not be placed on the register except by order of the court for any goods or description of goods which are identical with marks already on the register with respect to the same goods, etc., or so nearly resemble a registered mark as to be calculated to deceive (sec. 19).

Applications as accepted are advertised; the advertisements state the conditions, if any, imposed on acceptance (sec. 13). Notice of opposition to the registration of a trade mark may be given under sec. 14 of the act of 1905 (which replaces sec. 69 of the act of 1883). The registrar after consideration decides whether the opposition is well or ill founded. His decision is subject to appeal to the High Court or by consent of the parties to the Board of Trade (1905, sec. 14 [5]).

There may be added to any one or more of the "essential particulars" above enumerated any letters, words or figures, or a combination of these. But the right to the exclusive use of the added matter must be disclaimed A man is not required, however, to disclaim his own name, or trade name, or that of his place of business, if the name appears in the mark.

The register may be corrected on the request of the registered owner of a trade mark as to errors or changes of address in the name of the registered owner, or by cancelling entries of marks or by striking out classes of goods for which a mark is registered or by entering disclaimers or memoranda as to a mark, provided that they do not extend the rights given by the existing registration (sec. 33).

A registered trade mark may be altered or added to in matters not substantially affecting its identity (sec. 34). A registered trade mark may be taken off by order of the court on the application of a person aggrieved, on the ground that it was registered without a *bona fide* intention to use it in connection with a particular class of goods, and that there has not been any such *bona fide* user, or that there has been no such *bona fide* user during the five years preceding the application. Non-use may be excused if proved to be owing to special circumstances and not to any intention not to use or to abandon the use of the mark (sec. 37). (See *Re Hare's Trade Mark*, 1907, 24 R.P.C. 263.)

The register may be rectified by order of the court on the application of any person aggrieved, or in the case of fraud in registration or transmission of the mark on the application of the registrar (s. 35).

Effect of Registration.—Registration is effective for 14 years but is renewable (sec. 28). The registration if valid gives the proprietor the exclusive right to the use of the mark on or in connection with the goods in respect of which it is registered (1905, sec. 39). This rule is subject to the following qualifications. (*a*) Where two or more persons are registered owners of the same or substantially the same mark in respect of the same goods, no one of them shall as against any other of them have any right of exclusive user except so far as their respective rights have been defined by the court. (*b*) Registration of a trade mark does not entitle the proprietor to interfere with or restrain the user by any person of a similar mark upon or in connection with goods upon or in connection with which such person has by himself or his predecessors in business continuously used such trade mark from

a date anterior to the use of the mark by the registered proprietor, or to object to the registration of the other man's similar mark for concurrent user.

In all legal proceedings relating to a registered trade mark registration is *prima facie* evidence of validity, and after seven years from the original registration, or seven years from the passing of the act of 1905, whichever shall last happen, the original registration shall be taken to be valid in all respects unless it was obtained by fraud, or the mark is disentitled to protection as being calculated to deceive or (act of 1919, sec. 6 [11]) is the only practicable name of an article or substance manufactured under an expired patent. No word which is the only practicable name of any single chemical element or compound is registrable as a trade mark. This provision does not apply to a mark denoting only the proprietor's brand or make of such substance (act of 1919, sec. 6 [2]).

Registered trade marks are assignable and transmissible only with the goodwill of the business concerned in the goods for which they are registered, and are determinable with the goodwill (sec. 22). Associated marks are assignable and transmissible only as a whole and not separately (sec. 27) The owner of a registered mark may assign the right to use his registered mark in any British possession or protectorate or foreign country in connection with any goods for which it is registered, together with the goodwill of the business therein of such goods (sec. 22).

The assignments, etc., on proof of title, are recorded on the register (sec. 33). It is a condition precedent to an action for the infringement of a new trade mark that the plaintiff should be the registered proprietor of the mark at the time when the action comes on for hearing This last provision does not apply to an action for "passing-off" (*see* TRADE NAME). In actions for infringement, evidence of passing off, or that the infringing mark is calculated to deceive, is not necessary The court decides on the probability of deception by inspecting and comparing the marks (*Hennessy* v *Keating*, 1907, 24 R P C. 485).

The right to a trade mark lapses if the mark ceases to be distinctive and becomes *publici juris;* if it is separated from the goodwill (a trade mark can only be assigned with the goodwill); if the mark is applied by the trader to spurious goods (as where boxes of cigarettes were so labelled, in conformity with an alleged custom of the trade, as to indicate that they were of Russian manufacture, which was not the fact); or when the mark is abandoned (temporary disuse, however, is not abandonment unless the mark has in the meantime become associated with the goods of another trader), or where, as in the "linoleum" case (7 Ch. D 834) it has become the name of the goods, and so merely descriptive; or after 14 years where registration is not renewed. In dealing with a claim for infringement the court must admit evidence of the usages of trade as to the get-up of the goods for which the mark is registered, and of any trade marks or get-up legitimately used with such goods by other persons (sec. 43).

The Trade Marks Act, 1919, provided for the registration in a separate division (Part B) of the register of trade marks, of a new class of trade marks, viz., marks which for not less than two years had been *bona fide* used in Great Britain in connection with any goods whether for sale in Great Britain or for exportation abroad, in order to indicate that they are the goods of the proprietor of the mark (sec. 2). Such registration is *prima facie* evidence of exclusive right to the use of the trade mark (sec 4) The use of the word "Anzac" with any trade, business, calling or profession without the authority of a secretary of State, or the request of the Government of Australia or of the Dominion of New Zealand, is prohibited by a statute passed in 1916.

International Arrangements.—The Trade Marks Act, 1905, applies to the British Islands. By the international convention for the protection of industrial property (*see* PATENTS), which was signed at Paris in 1883, and revised at Washington in 1911, the signatory States (others have since acceded) agreed that the subjects or citizens of each State should, in all the other States, enjoy as regards trade marks and trade names the advantages that their respective laws then granted, or should thereafter grant, to their own subjects or citizens. So far as Great Britain is concerned the provisions made for carrying out this convention are contained in sec. 65 of the Trade Marks Act, 1905, and in sec. 91 of the Patents and Designs Act, 1907. The effect of that section is to confer on an applicant for the protection of a trade mark in one of the other contracting States a priority over other applicants for registration in Great Britain during the space of four months. The section does not, however, exempt the applicant from the conditions and formalities incumbent on ordinary applicants for registration in Great Britain; nor does the fact that the foreign application has been successful of itself give the applicant a right to have his mark accepted for registration. Guatemala and Salvador, also signatory parties, have withdrawn from the convention

The following is a list of the British Orders in Council that have been issued, applying to foreign countries sec. 91 of the Patents and Designs Act, 1907: Austria, Hungary, May 17, 1909 (art. 237 of Austrian Peace Treaty; as to Hungary, art. 220 of Treaty of Trianon); Belgium, June 26, 1884; Brazil, June 26, 1884, Bulgaria, July 14, 1921; Cuba, Jan. 12, 1905; Czechoslovakia, March 11, 1920; Danzig, Free City of, Nov. 21, 1921; Denmark (including the Faroe Islands), Nov. 20, 1890; Dominican Republic, Oct 21, 1890; Ecuador, May 16, 1893; Estonia, Feb. 20, 1924; Finland, Oct 11, 1921; France, June 26, 1884; Germany, Oct. 9, 1903; Greece, Oct 9, 1924; Honduras, Sept. 26, 1901; Italy, June 26, 1884; Japan, Oct 7, 1899; Latvia, Oct 12, 1925, Luxembourg, July 14, 1922; Mexico, May 28, 1889; Morocco Protectorate (French), Feb. 12, 1918; Netherlands, June 26, 1884 (East Colony), Nov. 17, 1888 (Curaçoa and Surinam), May 17, 1890; Paraguay, Sept 24, 1886; Poland, Nov. 25, 1919; Rumania, Oct 13, 1920; Yugoslavia, July 14, 1921; Spain, June 26, 1884; Sweden (and Norway), July 9, 1885; Switzerland, June 26, 1884, Syria and Lebanon, Oct. 9, 1924; Tunis, June 26, 1884; Turkey, Oct. 12, 1925; United States, June 12, 1887; Uruguay Sept. 24, 1886

By Orders in Council, made under the provisions of the Foreign Jurisdiction Acts, penalties have been imposed on British subjects committing offences against the imperial Trade Mark Acts or the Orders in Council issued thereunder, *e g*, Abyssinia; China and Korea (1904); Egypt (1899); Muscat (1904); Turkey (1899), Persia, Persian coasts or islands (1889–1901); Siam (1906); and Zanzibar (1906). Penalties for offences against the trade mark laws of British India are contained in the Bahrein, Muscat and Somaliland Orders in Council

The following is a list of the orders issued as to British possessions: Australia, Commonwealth of, March 26, 1907; British India, Oct. 13, 1920; Canada, Oct 11, 1923; Ceylon, Aug 7, 1905; New Zealand, Feb 8, 1890; South Africa, June 25, 1918; Trinidad and Tobago, Aug. 12, 1907. These Orders in Council are printed in the Index to the *Statutory Rules and Orders Revised*, in force up to Dec. 31, 1927.

Colonial Trade Mark Laws.—The British Colonies generally follow the model of English trade mark legislation

Legislation on trade marks is one of the subjects which the Commonwealth of Australia Constitution Act, 1900 (sec. 9, pt v., 51, xviii) places within the exclusive competence of the Federal parliament By the Commonwealth Trade Marks Act, 1905, sec. 20, provision is made for registration of trade marks throughout the Commonwealth, and subject to this act and other Commonwealth legislation the common law of England as to trade marks is applied throughout the Commonwealth. *See* also the Commonwealth Acts, 19 of 1912 and 7 of 1919, and 25 of 1922, extending the English acts, 1905–19 to territories under the authority of the Commonwealth.

In Canada the law as to trade marks (*Rev. Stats.* c. 63) has been regulated by Dominion acts, similar to English statute law. The following colonial laws also are based on imperial legislation: British Guiana, 27 of 1914; Ceylon, 15 of 1925; Cyprus, 17 of 1920; Union of South Africa, 9 of 1916, chap. iii.; Nigeria, 17 of 1910; Mauritius, 8 of 1913; Sierra Leone, 17 of 1913; Trinidad and Tobago, 15 of 1913.

Trade marks are excluded from the legislative power of the Government of Northern Ireland (Government of Ireland Act. 1920, sec. 4 [1] [13]), not from that of the Irish Free State (Irish

Free State, Constitution Act, 1922, sched 16 [8]), which has established its own law of trade marks by the Industrial Property Protection Act, 1927 (No. 16 of 1927).

United States.—Provision for the registration of trade marks in the United States was first made by an act of Congress of 1870; but that enactment was subsequently declared invalid by the Supreme Court (*U.S.* v. *Steffens*, 1879, 100 U.S. 82), on the ground that the Constitution of the United States did not authorize legislation by Congress on the subject of trade marks, except such as had been actually used in commerce with foreign nations, or with the Indian tribes. Congress legislated again on the subject in 1881 (act of March 3, 1881, Revised Stats, U S. secs. 4,937–47). The act of 1881 was repealed by an act of Feb 20, 1905 (sec. 592), which, as modified by an act of May 4, 1906, now regulates the subject. A trade mark may be registered by the owner if he is domiciled within the United States, including all territory under the jurisdiction and control of the United States (sec. 29), or resides or is located in any foreign country which by treaty, convention or law affords similar privileges to citizens of the United States (sec. 1) The right of persons domiciled in the United States was in 1906 extended to owners of trade marks who have a factory in the United States, so far as concerns the registration, etc, of trade marks used in the products of the factory (1906, sec. 3)

The United States policy is to require registration of all trade marks unless they (*a*) consist of or comprise scandalous or immoral matter; (*b*) consist of or comprise the flag or insignia of the United States, or of any State or municipality, or of any foreign nation, (*c*) are identical with another known or registered trade mark owned and used by another and appropriated to merchandise of the same description, or so nearly resemble such other marks as to be likely to cause confusion or mistake in the mind of the public or to deceive purchasers; (*d*) consist merely in the name of an individual, firm, corporation or association, unless it is written, printed, impressed or woven in a particular or distinctive manner, or is associated with a portrait of the individual; (*e*) consist merely in words or devices descriptive of the goods with which they are used, or of the character or quality of such goods, or merely of a geographical name or term; (*f*) contain the portrait of a living individual unless his consent is evidenced by an instrument in writing

Decisions of the examiners on applications or oppositions are subject to appeal to the commissioner of patents, and from him to the court of appeals for the District of Columbia (secs 8, 9) The general jurisdiction in trade mark cases is given to the Federal courts below the Supreme Court, which has power by certiorari to review the decisions of circuit courts of appeal upon such cases (secs 17, 18) The maximum protection given by registration is 20 years The protection given to marks already registered in a foreign country lapses when the mark ceases to be protected in the foreign country (sec 12) Certificates of registration are issued under the seal of the Patent Office.

Other Countries.—In France (laws of June 23, 1857, and March 3, 1890) trade marks are optional, but may be declared compulsory for certain specified articles by decrees in the form of administrative orders The decrees regulating registration are of Feb. 27, 1891, and Dec 17, 1892 The following are considered trade marks: Names of a distinctive character, appellations, emblems, imprints, stamps, seals, vignettes, reliefs, letters, numbers, wrappers and every other sign serving to distinguish the products of a manufacture or the articles of a trade. By legislation of Aug 1, 1905, and July 11, 1906, provision is made for marking certain classes of commodities, mainly food products, to prevent falsification and the sale of foreign products as French. *See* also law of March 9, 1911, ratifying the convention between France and Japan for the mutual protection of trade marks in China

Under the German trade mark law of May 12, 1894, any person whatsoever can acquire protection for a trade mark, and all foreigners in Germany are placed on an exactly equal footing with Germans in the eyes of the law, so long as they have a domicile (*Niederlassung*) within the State, *i.e*, a place of business or a residence which involves the payment of German taxes The registration of a trade mark expires *ipso facto* after ten years from its date, but may be renewed for a similar period. *See* also laws of June 2, 1911, and May 12, 1924, and regulations of April 30, 1920.

The following other foreign trade mark laws may also be noted: *Austria*, law of 1890 (published in Vienna on Jan. 6, and in Budapest on April 6, 1890), and amending laws of July 30, 1895, which enactment protects additions to trade marks, and Jan. 17, 1913, and law of May 24, 1919, providing for the renewal of trade marks under the old law. *Denmark* (law of April 11, 1890, an amending law of Dec. 19, 1898, which enabled traders to register words or figures, provided that these are not indicative of the origin, kind, use, quality or price of the goods, and a law of April 29, 1913, permitting associations to register collective names, and a law of Nov 13, 1903, as to Iceland). *Japan* (law of July 1 and regulations of July 2, 1899, and law of April 1, 1921) For offences against the Merchandise Marks Acts or Trade Marks Acts *see* MERCHANDISE MARKS

TRADE ORGANIZATION. The province of this article is defined by the limits of "trade" in the strict sense of exchange of commodities on a commercial scale and excludes the organization of production as well as that of the more special developments or concomitants of commerce such as banking, insurance and transport, and finally that of the final retail distribution. The unit in this restricted field which may properly be called "commerce" is the merchant, the man who buys and sells but neither produces nor consumes commodities; he does produce values. An essential element, even in early stages of civilization, he figures in the 14th century as an individual among the company of Chaucer's "wel nyne and twenty" pilgrims The corresponding group unit of his class, the chamber of commerce, had not arisen in the British isles when Adam Smith in the 18th century observed and demonstrated the essential nature of the evolution which had taken place in industry through the already substantially advanced division of labour. This was due partly to the inherent "individual" nature of the simple process of commerce and partly to the national independence of character

In France, as is related in more detail later, a more centralizing Government had created organizations of this name "chambres de commerce" which were incorporated into the administrative system of the country and given an official status and functions such as the control or management of public commercial institutions, including inland waterways and port and harbour works the construction of which is usually financed by the chambers of commerce either wholly or jointly with the State or other authority The relatively high position of French chambers of Commerce in the administrative sphere is further illustrated by the fact that during the war of 1914–18 they in common with municipalities were allowed even to issue paper money and tokens for small change, a function which was in fact exercised by practically all these bodies and so extensively that by 1919 their notes formed the chief currency for small change in France. These powers were terminated by the Stabilization Law of 1928.

In the British isles, on the other hand, chambers of commerce were, and remain, voluntary associations of a somewhat loose texture, exercising very little, if any, compulsion upon their members, and endowed with few definite functions in relation to the comparatively light administrative framework within which trade has to be conducted.

PART 1. TRADE ORGANIZATION IN GREAT BRITAIN, AND GENERALLY

The earliest British chambers of commerce were formed in

Jersey in 1768, in Glasgow in 1783, in Dublin in 1785 and in Edinburgh in 1786, the year in which the Board of Trade was re-established by the order in council which is still the statutory authority for that body's existence. It was not until 1794 that a similar body, the "Commercial Society" of Manchester was founded in England This society had the definite objects of preventing "the depredations committed on mercantile property in foreign parts"; of obtaining increased safety for trade and more regular payments, and of co-operating jointly in all applications to Government. (*Chapters in the History of the Manchester Chamber of Commerce* by Elijah Helm.) It at once engaged in active correspondence with the Government in regard to difficulties arising out of the war with France Other Commercial Societies soon came into existence at Birmingham, Leeds and elsewhere, and joint meetings of delegates from these several bodies were held in London The Manchester society, however, ceased to hold meetings after 1801 and was not revived until 1820, then as "the Manchester chamber of commerce" Meanwhile chambers had been established at Belfast (1796), Birmingham (1813) and Newcastle-upon-Tyne (1818). The subsequent chambers of outstanding importance were those established at Liverpool (1851), Sheffield (1857), Bradford and Cardiff. The London chamber, which was not founded until as late as 1881, has a direct membership of over 8,000, apart from 52 affiliated associations (covering thus an indirect membership of 50,000) The requisites for the merchant, apart from the main material need for money-credit are integrity and the reputation for integrity, knowledge and judgment; also a general state of lawfulness with stable and liberal economic conditions Similarly the main functions of the typical British chamber of commerce may be analysed as follows —

(a) Maintenance of a high standard of integrity and commercial conduct among their members

(b) Provision of information in the shape, *e.g*, of trade statistics, foreign tariffs and regulations, exhibitions of foreign samples

(c) Provision of advice —
- (i) general as to business methods and overseas markets
- (ii) particular, as regards individual difficulties
- (iii.) legal, *e g*, as to shipment of goods and contract conditions
- (iv) expert opinions on values and qualities, *e.g.*, through testing houses such as those at Bradford and Manchester

(d) Provision of assistance, legal, *e g*. for contesting issues of general importance to merchants and for recovery of individual debts, also in regard to difficulties encountered in dealing with foreign administrations in regard to which Government assistance will frequently have to be sought

(e) Performance of administrative service, *e g*, certificates of origin and other documents necessary to foreign trade

(f) Arbitration and settlement of disputes

(g) Formulation of policy and representations to Governments, in regard, *e.g*, to
- (i) domestic legislation affecting commerce
- (ii.) foreign tariffs and regulations
- (iii.) other matters of common interest to their members

Trade Protection Societies.—Among their functions that of recovering debts or of protecting the trader from loss through the insolvency or dishonesty of those with whom he has to deal is to a large extent fulfilled by *trade protection societies* which afford special facilities for the collection of debts where this presents difficulty. In towns of minor commercial importance the chamber of commerce is often combined with such a society. The Association of Trade Protection Societies of the United Kingdom has been formed to promote the common purposes of these bodies.

In the typical chamber of commerce the merchant is predominant, but the manufacturer or industrialist who, to a large and increasing extent, is also the merchant for his own goods is also strongly represented An analysis of the membership of the London chamber (1928) gives out of a total of 8,061 members, 3,264 merchants (to which may be added 376 brokers and agents) and 2,906 manufacturers; other groups illustrative of the diverse interests included in commerce are banking (214) insurance (170) and transport (144)

Chambers of commerce have themselves become highly organized bodies. The London chamber is divided into 69 sections according to overseas countries dealt with, commodities or trades, and special aspects; Manchester has 15 general sections including the Testing House, 7 being on a geographical basis Apart from this there are numerous committees to deal with the various aspects of commerce—transport rates and services, postal and telegraphic matters, commercial law. Of special importance are those on arbitration and education.

The London court of arbitration is jointly managed by the London chamber and the corporation of London by which bodies it was formed in 1892. It consists of 12 representatives of the chamber and 12 of the corporation. Its function is not itself to hear cases but to appoint duly qualified arbitrators to deal with disputes which are referred to it. It serves a very useful purpose in providing a ready, efficient and inexpensive means of settling commercial disputes Manchester also possesses a tribunal of arbitration, a special department which itself gives awards. The Dublin chamber of commerce has established (1927) a court of arbitration for commercial disputes at its offices in Dublin available both for voluntary references to arbitration and for arbitration of cases referred by the law courts.

The provision of a continuous supply of educated young men and women who can carry on the great work of commerce, which tends always to become more exacting, is one of the chief cares of the chambers of commerce. Valuable work is done in London and other large centres by the institution of examinations for certificates in commercial subjects and by the grant of scholarships enabling chosen students to study languages and commercial conditions abroad In 1927 over 26,000 entered for the London junior and senior commerce certificates and 13,499 certificates were granted. Apart from these direct incursions into the educational field the chambers watch educational policy from the business man's standpoint

In addition, chambers of commerce undertake from time to time special pieces of work of which a good example is afforded by the enquiry which the joint committee of Cotton Trade Organizations convened by the Manchester chamber of commerce made into the costs of production and marketing overseas in the Lancashire cotton trade in 1927–28 The object of the Committee was described by themselves as being "to bring about the changes required by changed conditions more speedily, more efficiently and with greater regard for the common good of all sections than would be done by individuals in the trade, if left to themselves"; in other words a voluntary organization is to be developed

True to their independent and voluntary character the British chambers of commerce were slow in associating together for common purposes in any permanent form The Association of British Chambers of Commerce was formed in 1860 but then it consisted only of 16 chambers and it was not until the closing years of the 19th century that the association can be said to have embraced the whole body of chambers Even now the association is in the nature of a loose federation, though it plays an important part in the formation of the policy of the commercial community and is the channel for authoritative advice and appeal to the Government.

Trade Associations.—Chambers of commerce, and such closely allied bodies as the Manchester Importers and Exporters Association, may be said to organize the trade of the country on a territorial basis In some cases, such as notably Manchester for cotton or Sheffield for steel, the district which is served by the chamber produces the main share of the country's whole output of the commodity in question. But this is exceptional, and with the great majority of the modern industries the factories of each are found in several distant parts of the country, and for this reason, and because naturally each industry presents its own special problems, practically every one has set up its own national trade association The nature and activities of these bodies vary greatly. Apart from employers' associations formed primarily to deal with trade unions in regard to wages, hours, and conditions of labour (as to which *see* LABOUR), there are general associations capable of dealing with all other subjects of interest to the producers or traders in each particular industry While in general these exert little control over the actual conduct of each member's business as, *e g*, in the matter of prices or credit terms, there are examples of bodies which exhibit closer degrees of association for definite purposes, and the study of these gradually impinges

upon that of cartels, trusts and amalgamations. (*See* TRUSTS.) Important examples of the more common type of trade association for general purposes are the Mining Association, the National Federation of Iron and Steel Manufacturers, the Cotton Spinners' and Manufacturers Association, the Wool Textile Delegation and the British Engineers' Association. Such bodies are in general concerned in a greater measure with production than with any problems of the merchant, but their work provides a valuable supplement to that of the local Chambers in the efficient organization of commerce. (*See* also INDUSTRY.) Just as the Association of British Chambers of Commerce constitutes a centre and head for these bodies, the trade associations of Great Britain are grouped under the Federation of British Industries, which was founded in 1916, and numbers among its members over 160 separate Trade Associations as well as over 2,350 individual firms. The federation does not deal with questions affecting wages and conditions of labour, such questions being left to the National Confederation of Employers' Associations. It co-ordinates and supplements, from a national point of view, the work of the individual associations It has representatives and correspondents in nearly every country in the world and is thus able, apart from its more general work, to promote immediately the sale of its members' products.

The federation deals primarily with its members on the industrial group system, but it approximates to the organization of the chambers of commerce in maintaining district offices and secretaries in most of the principal cities of Great Britain and in providing its members with a method of expressing their views on the geographical basis through district committees.

In the United States, where trade associations are greatly developed, the central commercial organization, the United States chamber of commerce, corresponds with both the Association of British Chambers of Commerce and the Federation of British Industries, since it is a federation not only of local chambers of commerce, but also of other bodies included among which are many national trade associations.

Chambers of Trade.—The bodies known as Chambers of Trade form a territorial organization representative of the distributive side of trade and so supplementary to the Chambers of Commerce. They are linked together by the National Chamber of Trade inaugurated in 1897 and incorporated in 1925 which has a membership of upwards of 350 local chambers of trade and traders' associations The Incorporated Association of Retail Distributors which commenced its operations in 1920 and has attained a membership of 200 large retail stores forms a complement in this respect to the National Chamber of Trade. These bodies are mentioned here in view of their part in the national organization of trade as a whole, but their main activities lie outside its proper sphere and are treated under RETAILING.

Produce Markets.—Again parallel with the development of topographical associations of merchants and of associations for particular "trades" has been that of the organization of the process of buying and selling of specially important individual commodities or of produce markets. For the more important basic foodstuffs and raw materials the markets became concentrated so as to serve increasingly large areas, and, for the more regular and efficient conduct of their primary purpose, system and regulation arose, the market becoming a "produce exchange." Following the same distinction in character that is found between British and Continental chambers of commerce, the British "Exchange," originating from voluntary association, is self-governing and derives its effective powers from custom and not from statute; on the other hand the French "bourses de commerce" work under strict Government control; so, also in Germany and generally on the Continent. Some of these institutions, *e.g.,* the "Baltic" (Baltic Mercantile and Shipping Exchange Ltd.) dealing chiefly in shipping (charter parties) and grain, and the Corn and Coal Exchanges of London, were founded about the middle of the 18th century, but the greater number are of much later origin. The Liverpool Corn Trade Association dates from 1853, provides a futures market for wheat and maize and controls the whole of the wheat trade of the port; a similar body is the London Corn Trade Association dating from 1878 working closely with the "Baltic." The London Produce Clearing House Ltd., established in 1888 deals with forward contracts in coffee, sugar and many other commodities. The largest corn exchange is that of Chicago dating from 1848 and operating under a State Charter of 1859. The New York Produce Exchange was formed about the same time and provides for the markets in a number of commodities; cotton and coffee, however, had their separate exchanges in New York in 1870 and 1887 respectively, and the great southern cotton exchange is at New Orleans. The Liverpool Cotton Association Ltd., assumed its present form in 1882. These bodies are generally owned and managed by their members. They develop the organization of the markets by standardization of grades and by perfecting the general methods of business and the rules under which the sales are conducted.

With Chaucers' Merchant, whose interest in safe navigation was limited to the narrow seas between Holland (Middelburg) and the East coast of England (Orewell), went to Canterbury a shipman who knew all the havens from the Baltic (Gothland) to Spain. Two centuries later the merchants were joining together to engage in large enterprises of trade in distant waters with their own ships. In 1555, for example, the Muscovy Merchants Company was granted a royal charter to trade with the newly discovered northern ports of Russia and other new markets. Another royal charter was granted to the Eastland Company in 1579 to continue their trade with the Baltic. The Levant Company received charters from Elizabeth (1581–1593) and survived until the 19th century, as did the London East India Company (1600). The rival merchant venturers on the Continent followed with the Dutch United East India Company (1602) and the French East India Company (1664). True to the divergent British and French conceptions of policy these trading companies were, with England, merely developments of individual enterprise self-governing and self-supporting; with France, like the chambers of commerce they were rather organs of the State controlled bureaucratically.

These developments were of political importance rather than economic; politically they were a powerful example for the joint stock organization of business enterprise, but they did not assist markedly in the special evolution of trade or merchant organization. At the same time they do, however, represent yet another direction in which trade has become organized, *i e*, according to the region of the world with which the trading activities are carried on. Shipping and commerce have separated so that examples of shipowners acting as merchants or vice versa are rare; it is also rare that the trade between any particular parts of the world is concentrated in the hands of a single group of merchants or of a trading company in the old sense. Consultative bodies devoted to such special trades exist, however, such as the China Association and the British Merchants' Morocco Association, both of long standing. Among the more modern bodies of this kind may be mentioned the British and Latin American chamber of commerce founded in 1916 and open to all firms in the United Kingdom or in Latin America. There are also special committees of the larger chambers of commerce devoted to the trade with special geographical regions as, *e.g.,* the Far Eastern and Uruguayan committees of the London chamber and the China and Far East and Central and South America committees of the Manchester chamber.

Chambers of Commerce in the British Empire.—The earliest chamber of commerce to be established in British territory overseas was that founded at New York in 1768. After that the Commercial Exchange of Cape Town which later, 1861, became the Cape Town chamber of commerce, was the earliest "colonial" body of the kind, having been founded in 1804. Between 1830 and 1840 a group of chambers of commerce were founded in British India—at Calcutta (1834), Bombay and Madras (1836) and Ceylon (1839). In 1840 chambers were founded in Australia (Adelaide) and Jamaica; in 1845 in Canada (Toronto). During the second half of the 19th century the commercial communities of all the chief cities of the empire formed chambers which are very similar in character to those of Great

Britain. In most of the dominions there are general associations of these chambers corresponding to the Association of British Chambers of Commerce in Great Britain, *e.g.*, the Canadian chamber of commerce (1927), the Associated Chambers of Commerce of India which embraces 17 chambers, the Associated Chambers of Commerce of the commonwealth of Australia and the Association of Chambers of Commerce of South Africa. There are a Canadian, and an Australian, Chamber of Commerce in London.

The further concentration of the commercial opinion of the empire was early recognized as desirable and a series of congresses of the chambers of commerce in all parts of the British dominions began in 1886 with that convened by the London chamber when 97 such bodies were represented; at the third congress in 1896 when Joseph Chamberlain was honorary president 162 chambers took part. In 1911 a permanent body called the British Imperial Council of Commerce was established which is now known as the Federation of Chambers of Commerce of the British Empire. This body continues the series of congresses at intervals of three years and at the eleventh held at Cape Town in 1927 74 chambers participated The membership of the federation itself is 169 chambers of commerce and associations of chambers, fully representative of every part of the empire. By means of these congresses matters affecting to inter-imperial commerce are examined and a common policy postulated mainly for the guidance of the Governments of the empire, on such subjects, as taxation, communications, empire development and trade policy, research and education. Their work is thus ancillary to that of the imperial conferences and the imperial shipping and economic committees together with the Empire Marketing Board (as to which *see* below).

Organization in regard to the several trades or industries is established in the dominions as in Great Britain and naturally to an extent commensurate with their industrial development

British Chambers of Commerce in Foreign Countries.—British chambers of commerce in foreign countries advise and assist British diplomatic and consular officers and serve the general interests of British trade with the respective countries or districts in which they are situated They vary in constitution especially in regard to the extent to which foreign elements are admitted; while some are closed to foreigners others admit them on equal terms; in yet others a midway course is adopted. On the question of subsidation of these bodies by the Government a Foreign Office committee in 1920 reported definitely against the grant of Government subsidies and British chambers of commerce abroad are quite independent of Government funds Such chambers exist in nearly every important foreign country and they are particularly strong in China

Foreign Chambers of Commerce in Great Britain.—Reciprocally, foreign chambers of commerce are free to establish themselves in Great Britain and generally throughout the empire and to carry on the normal activities of such bodies In this way most of the leading commercial countries are represented in London.

In some countries on the other hand foreign chambers can only work under certain restrictions. This is easily understood in the case of those countries in which the national chambers of commerce have an official character.

Commercial Travellers.—Commercial travellers may be regarded as a separate species of the genus merchant; they are employed by merchant firms or by manufacturers who, to that extent, act as their own merchants to obtain orders from the retailers and they generally carry with them samples of the goods their principals wish to sell. The beginning of this development of trade coincided roughly with the industrial revolution, the consequent need for extended markets for factory production and the provision of better facilities for travelling and transport; thus commercial travellers and chambers of commerce.both date from the late 18 century, though both have developed enormously since that time.

Co-operative System.—The co-operative system of trade, which in recent years has assumed greatly increased importance, in so far as it succeeds in bringing together under one management the manufacture or distribution of commodities replaces the merchant, the intelligent centre of distribution guided by his sense of profit or reward for getting the right goods into the hands of the right people, by the appropriate official of the co-operative enterprise guided in the same task by, no doubt, more precise information and possibly free from the necessity, as from the opportunity, of showing in the shape of a demonstrable "profit" the positive success of his transactions. This is equally true whether the system is co-operative in the special sense as embracing the consumer or is simply an amalgamation of ordinary private enterprises, cutting out the independent merchant to a greater or less extent. Whatever may be the ultimate expansion of such systems of trade organization the essential function of distribution which the merchant performs will remain and it is difficult to imagine the rise of any economic practice which will render him or the chamber of commerce obsolete

Closely connected with co-operative marketing is standardization which has attained a considerable development in the case of agricultural produce and is receiving an increasing amount of attention as part of the general process known as "rationalization" which appears to consist largely in the application of common sense principles to trade organization

International Trade Organization.—Organization, in no matter what sphere, is tending towards the establishment of international principles and institutions. In the sphere of commerce the International chamber of commerce has already attained wide recognition, and plays an important part in the work of unifying and ameliorating the conditions under which the trade of the world may be conducted A piece of work of particular importance in the proper organization of merchant business is being undertaken by the International Law Conference in drawing up rules relating to c i f contracts and cognate questions of the rights and duties of the buyer and seller. The common interests of the various national trades, which it has been noted are served by innumerable trade associations, are dealt with by such bodies as the International Association of Federations of National Industries, while international cartels, trusts or combines are growing slowly, if with much difficulty and in face of apprehension (*See* INTERNATIONAL TRADE ASSOCIATIONS AND CONGRESSES)

League of Nations.—Above all the economic branches of the League of Nations afford a means of co-ordinating the different efforts of the various countries and interests and giving their more practical aims and ideals an authority which increases steadily In particular, apart from the work of removing trade barriers. the League is lending valuable aid to the actual organization of world commerce in such matters as the attempt to establish uniform nomenclatures for customs and statistical purposes, to codify the law and practice respecting bills of exchange and cheques, and to promote the study of *rationalization* (*q.v*). Of definite achievements which contribute positively to the organization of international trade, the protocol on arbitration clauses in commercial matters of 1923 which has been ratified by 17 States together with the complementary convention on the execution of foreign arbitral awards of 1927, afford important guarantees to merchants of effective means for the settlement of disputes

THE BRITISH GOVERNMENT AND TRADE ORGANIZATION

So far we have been concerned with that part of the organization of trade which has been in the main voluntary; we now come to consider the extent to which the British Government has engaged in that sphere. The functions of the British Board of Trade in relation to commerce had, in consequence of the disappearance of the English protecting tariff in the middle of the 19th century and of the creation of a commercial department in the Foreign Office (1871), been reduced practically to those of obtaining information as to the tariffs of other countries and of preparing trade statistics. Subsequently the Board regained its functions in connection with the negotiation of commercial treaties, with representations to foreign Governments and generally with the protection of British trade interests abroad The proper performance of these duties required improved means of

obtaining information as to commercial conditions abroad and the complete triumph of the laissez faire principle in its application to foreign trade in the middle of the nineteenth century was followed by a gradual policy of the State taking a judicious interest in commerce This development in policy was marked by the appointment of a few commercial attachés to embassies and legations dating back to 1880; by the establishment in 1900 of a commercial intelligence branch of the Board of Trade to provide a new service of commercial information for British traders; and by the establishment in 1908 of trade commissioners in Canada, Australia, New Zealand and South Africa as a result of recommendations approved by the Colonial Conference in the previous year The State thus began to take a share in the provision of information which, as we have seen, may be claimed to be one of the functions of the chamber of commerce

During the World War, Government intervention in matters affecting trade and commerce was, of course, urgently necessary in many directions. These activities were gradually discontinued after the cessation of hostilities but one permanent development remained. This was the conversion of the commercial intelligence branch into a department of commercial intelligence which in turn became in 1917 the department of Overseas Trade, a joint department of the Foreign Office and Board of Trade

The department of Overseas Trade has now at its disposal for the purpose of obtaining commercial information and of assisting British commerce generally a much more comprehensive organization overseas than has ever existed previously In the empire there are 13 trade commissioners stationed in the dominions, India, and some of the more important colonies In other parts of the empire the department has the assistance of imperial trade correspondents In foreign countries in place of the prewar commercial attachés a new service, styled the commercial diplomatic service, has been established consisting of officers styled commercial counsellors in the higher grades and commercial secretaries in the lower grades These officers are stationed in the most important foreign capitals—about 25 in number They are members of the staff of the British embassy or legation at the place in question and an important part of their duties is to give the ambassador or minister assistance in all matters affecting commerce with which he may have to deal The service is administered by the department of Overseas Trade

Consular Service.—The consular service has been under the control of the department of Overseas Trade since Oct 1919 The work of British consular officers has necessarily always been of a very diverse character but since the service has been associated more directly with the department of Overseas Trade, greater stress has been laid upon the commercial side of their work, in respect of which they are under the general supervision of the commercial diplomatic officer.

Department of Overseas Trade.—The department of Overseas Trade, which has its headquarters in London, is organized on a carefully planned system On the one hand there are geographical sections consisting of officers with specialized knowledge of particular markets, on the other hand, there are trade sections staffed by officers specializing in groups of commodities, who are in contact with the particular industries of this country

The main function of the department at home and of the three overseas services is to bring to the attention of British manufacturers and traders not only specific openings for export trade which come to their notice, but all general information of an economic or commercial nature which may be of assistance in their trade abroad All information received by the headquarters office from its overseas officers, is brought by that office before traders by direct dissemination, or by publication in the Board of Trade *Journal*, which was established in 1886, has been issued weekly since 1900 and forms a continuous record of the various commercial laws and regulations, and especially of the customs tariffs of the world. The trade commissioners, commercial diplomatic officers and certain of the consular officers furnish reports on the economic conditions of the countries forming their district which are published in a regular annual series Apart from the work of distributing information, the department and its overseas officers are able in many ways to be of assistance to British firms in connection with difficulties which they may be experiencing or in providing their representatives with facilities when paying business visits abroad. The overseas officers are constantly in touch with representatives of British firms visiting their country and as an additional means of direct contact between them and commercial men at home systematic arrangements have been made for official visits by the overseas officers to Great Britain bringing them into contact not only with the headquarters of the department but also with the business community.

Exhibitions.—Another branch of the department is the exhibitions and fairs division, whose principal function is the organization of the British Industries Fair. This fair was first held in 1915 and is held annually in London and Birmingham. It consists exclusively of a display of goods of British manufacture in a great variety of trades Bona fide trade buyers are alone admitted, except for special hours when it is thrown open to the public and the fair has now become a permanent feature of the trade organization of this country The London section of the fair is organized and controlled by the department of Overseas Trade, whereas the Birmingham section is organized under the auspices of the Birmingham chamber of commerce.

The exhibitions and fairs division is also responsible for the organization of official participation in international exhibitions

Export Credit.—As regards Government provision for export credits, the first scheme adopted by the British Government was started in 1919 after the war of 1914–18 had left the finances and currencies of Europe in a more chaotic state than commercial men of that generation had ever known, and at a time when some external aid was required to facilitate the resumption of trade with countries whose commerce and industries had been crippled by the war. Under the original scheme advances were made to exporters without recourse in respect of shipments to such countries, but importers were required to provide approved collateral security This scheme was replaced in 1921 by a system which was extended to all countries except Russia, and under which payment of a proportion of bills of exchange was guaranteed by the exports credits department The scheme of 1921, which was devised to meet still rather abnormal trading conditions was by no means simple, but it undoubtedly brought to this country a certain volume of business, which would otherwise have been placed elsewhere As the major disturbances in international trade passed away a new scheme was instituted in 1926 on the recommendation of a committee of bankers and others appointed to examine the general question of credit insurance Under the present (1929) system the exports credits guarantee department insures the payment at maturity of a proportion, not exceeding 75%, of bills of exchange drawn upon approved importers overseas in respect of goods manufactured in the United Kingdom The greater part of the department's business is done under contracts or insurance policies designed to facilitate normal business in the principal exporting industries.

British Imperial Trade Problems.—There were also created, in accordance with resolutions of imperial conferences, during the period of reconstruction after the World War, special new organs for the authoritative study of the economic problems of the British empire, the first being the imperial shipping committee appointed in 1920 This body, which was the first to be responsible to all the several Governments of the empire, included within its early activities matters of such primary importance to merchants as the rebate system and the liability clauses in bills of lading. In 1925 came the appointment on the same basis of the imperial economic committee, which has since presented reports dealing with the preparing for market and marketing of meat, dairy produce, fish, poultry and eggs and honey, and has conducted enquiries into empire tobacco and empire timber trades.

On the recommendation of the imperial economic committee there was appointed in 1926 the Empire Marketing Board to advise the secretary of state for dominion affairs in the administration of a parliamentary grant of £1,000,000 placed at his disposal for the purpose of furthering in the United Kingdom the sale of empire produce from home and overseas. The main work of

this board falls under three headings, publicity, scientific research and economic investigation.

The Board's contributions to the merchant side of the complex undertaking of furthering the sale of empire produce include the furnishing of information as exemplified in the *Weekly Fruit Intelligence Notes* and the organization of trial shipments, while assistance is given to experimental and research work on refrigeration and the grading, packing and transport of foodstuffs.

III. TRADE ORGANIZATION IN THE UNITED STATES

A. **Commercial Associations.**—Trade organization in America naturally commenced on the lines of the British system and its independent development since has not fundamentally departed from those lines. The oldest American commercial organization is the New York chamber of commerce which, as has already been stated, was founded in 1768 In the words of its charter, dated 1770, its object was "to carry into execution, encourage and promote by just and lawful ways and means such measures as will tend to promote and extend just and lawful commerce" It has formed the prototype of all the very numerous chambers of commerce and boards of trade (as some of them are called) which have now been formed in every place of importance throughout the United States The commercial interests of the United States as a whole are represented by the important voluntary organization known as the United States chamber of commerce which is a federation of local chambers of commerce, boards of trade and similar bodies, including a considerable number of national trade associations It is organized into departments relating to all the more important aspects of business. Its chief functions are those of co-ordinating and giving effective expression to the views of its member bodies on questions of national policy and of furnishing commercial information

A number of American chambers of commerce have been established in foreign countries, the earliest of which was the American chamber of commerce in Liverpool dating from 1801, a body which has now been replaced by the American chamber of commerce in London The American chamber of commerce in Paris is one of the most important foreign associations on the Continent of Europe and there are other American chambers of commerce in Germany, Italy, Spain and Belgium; also in the chief South American countries and in Mexico In China there are American chambers of commerce at Peking and at several ports.

American commercial museums such as those at Philadelphia and San Francisco have been founded to assist American manufacturers and merchants in securing wider foreign markets for their products Besides possessing valuable collections of commercial samples the museums have elaborate indexes of foreign customers and of American manufacturers which are available to chambers of commerce and similar bodies.

B **State Departmental Organization.**—The Government department of the United States which is primarily responsible for Government policy in relation to commerce is the department of Commerce but the department of State (which corresponds to the British Foreign Office) gathers trade information through its consular officers, their reports being disseminated by the department of Commerce Besides the usual statistics of trade and production, the United States department of Commerce issues a monthly *Survey of Current Business* which covers in addition such items as stocks, new orders, unfulfilled orders for every field of industry and commerce of importance, and to gather some general indications from this mass of separate data index numbers have been devised so that the *Survey* concentrates into a very small compass the entire commercial and industrial situation in the United States. It is the department of State which is looked to by American trade interests when these encounter difficulties abroad such as discriminatory or arbitrary treatment on the part of foreign Governments. In the matter of tariff policy, however, it is the United States tariff commission which has to gather the facts relating to all aspects of the United States tariff and to report them to Congress and the president.

U.S. Bureau of Foreign and Domestic Commerce.—The bureau of Foreign and Domestic Commerce is the department of Overseas Trade of the United States—it is the chief source of information of foreign markets for the American exporter, information which it derives from 45 commercial attachés and trade commissioners abroad. There is also a domestic commerce division established in 1923. The bureau is organized similarly to the British department of Overseas Trade on a combined basis of 14 commodity divisions and of three regional sections. Latin American, Far Eastern and European It publishes weekly *Commerce Reports* conveying a mass of information on every aspect of foreign trade. Other divisions of the bureau whose titles sufficiently indicate their general function are the finance and investment division, the transportation division, the foreign tariffs division and the division of (foreign) commercial laws, statistics and statistical research. The commercial intelligence division compiles an index of foreign business firms and indicates the general nature and standing of some 75,000 firms.

The bureau maintains local offices in several American cities and has made arrangements with representative chambers of commerce whereby these are used as local branches of the bureau.

C. **Unfair Practices.**—An important function in relation to the ordinary practice of commerce is exercised by the Federal trade commission which deals with complaints of unfair methods of competition or trade practices In important cases it calls together the representatives of the trade concerned and gets them to agree to declare what practices should be considered unfair Having commenced its activities in this direction in 1917 it is building up a body of law to guide American business men

For details *see* FEDERAL TRADE COMMISSION

IV. TRADE ORGANIZATION IN FRANCE

Chambers of Commerce.—French chambers of commerce owe their origin to the city of Marseilles, where, in 1599, the town council, which had hitherto looked after the commercial interests of the city, found it no longer possible to combine commercial with municipal functions, and established an association which it called the "chamber of commerce" to take up the commercial part of its duties This seems to be the first time that the title was used Although the new chamber soon became a most important body, *lettres patentes* were not granted until 1779 It settled the merchant law and the customs of the port, was entrusted with the appointment of consuls and the control of French consulates in the Levant. fitted out expeditions against corsairs, owned fleets, sent embassies to the Barbaresque countries, and also organised commercial missions Louis XIV. conceived the idea of a system of organizations which, whilst not being allowed to become so dangerously powerful as that of Marseilles, would nevertheless be useful in other towns, and in 1700 he caused an *arrêté* to be published, ordering the creation of chambers of commerce, which were entrusted with the nomination of deputies to the royal council of commerce which had just been created in Paris. Chambers were consequently established in Lyons, Rouen, Toulouse, Montpelier, Bordeaux, La Rochelle, Lille, Bayonne, Amiens and other towns. These bodies, however, did not exercise much influence under the monarchy. Including the Marseilles chamber, they were suppressed, with all trade guilds and other trade associations, in 1791. Napoleon re-established the chambers by decree of Dec. 24, 1804

They are now (1929) regulated by the law of April 9, 1898, modified by the law of Feb 19, 1908, which codified, altered and completed previous legislation on the subject Under this law, chambers of commerce can only be established by a decree countersigned by the minister of commerce, upon the advice of the municipal council of the place where the chamber is to be, of the general council of the department, and of the existing chambers of commerce of the district The members of French chambers of commerce, whose number is fixed for each chamber by the minister of commerce, are elected by the commercial houses paying *patente*, a special tax levied upon persons engaged in trade

Their functions, which are consultative and administrative, are set out in part ii. of the law of 1898. The government is bound to take their opinion regarding the regulation of commercial usages, the establishment of public institutions of a commercial or finan-

cial nature, such as "bourses de commerce" or commercial exchanges, and of tribunals of commerce, the improvement of transport and communications, the application of laws of a local character, the sale price of prison-made goods and the tariff for prison labour, and local public works, and loans or taxation in connection therewith. On the other hand, they are allowed to submit observations to the government, without being asked, on proposed changes in the commercial or economic legislation of the country; on customs tariffs and regulations; on railway, canal and river rates; and on transport regulations. As regards their administrative functions, they may be authorized to establish and administer such institutions as bonded warehouses, public salerooms, fire-arm testing establishments, conditioning rooms for wool, silk and other commodities, commercial, professional, or technical schools and museums They may be granted concessions for public works, and may undertake the carrying out of public services, especially in regard to the ports, docks, canals and navigable rivers in their districts, which in general they manage under the supervision and control of the State exercised through local resident officials In 1924 a new policy was incorporated by laws which made Havre and Bordeaux autonomous, *i.e.*, independent of State control, and placed them under bodies nominated as to the great majority of their members by the chambers of commerce of the city and of neighbouring towns in each case. Since the World War the chambers of commerce have undertaken most of the burden of new expenditure on ports.

Previous to 1898 it was illegal for chambers of commerce to hold joint meetings for the discussion of matters of public interest, and they were not even allowed to correspond or consult in any way, except through the medium of the minister of commerce. The law passed in that year relaxed this prohibition.

French Chambers of Commerce Abroad.—When, in 1873, British merchants in Paris started a British chamber of commerce in the French capital, the French government looked rather askance at the new venture, and M. Léon Say, when minister of commerce, even threatened it with forcible dissolution unless the title "chamber of commerce" was dropped. This demand was not ultimately pressed, and the services rendered by the British chamber soon opened the eyes of the French government to the advantages which they might derive from the formation of similar institutions to represent French commercial interests abroad In 1883 the minister of commerce started the organization of such chambers, which endeavoured to combine to a certain extent the French and the British systems, and upwards of 50 French chambers of commerce have been established in foreign countries, including six in Spain, four each in Belgium and Western Germany, and the only foreign chamber of commerce in British India (the French chamber of commerce for Western India and the Persian gulf at Bombay). There is a French chamber of commerce in London and another at Liverpool.

Foreign Chambers of Commerce in France.—Most of the leading commercial countries of the world are represented by chambers of commerce established in Paris, of which the British chamber is the oldest. There are also Belgian, British, Italian, Spanish and Swiss chambers at Marseilles. Spain has in all as many as seven chambers in France.

Consultative Chambers of Arts and Manufactures.—These institutions bear to industry, as their name indicates, much the same relation as do chambers of commerce to commerce. They were instituted by Napoleon as part of the complete system of economic organization which he intended to give France, but are now regulated by decrees of 1852 and 1863. They consist of 12 members elected by manufacturers and merchants and are under the control of the minister of commerce; they are supported by the municipality of the town to which they belong.

Syndical Chambers of Trade and Industry.—By the side of the official trade organizations other associations have grown up, which, although regulated by law, are in the nature of voluntary and self-supporting bodies, viz., the syndical chambers of trade and industry. The repeal in 1884 of the law of 1791, which prohibited the formation of trade or professional associations, was the signal for the formation of those chambers, which soon acquired great influence.

These bodies are organized primarily for the purpose of representing and bringing together the interests of the employers and the employed severally, and are divided into chambers of each of these two groups, except in regard to professions where there is a single syndical chamber, as for example, in the case of the brokers (agents de change) of the French bourses de commerce. Syndical chambers do not require Government authorization, and they can only be dissolved by the French courts on the ground of infringement of the provisions of the law of 1884. They take part in the election of judges of the tribunals of commerce.

Out of this organization has been created since the war the central organ of French industry known as the Confédération Générale de la Production Française, formed on the proposal of the minister of commerce in 1919 "to contribute to the development of the productive power and export trade of France, and to co-ordinate the activities of the syndicates and professional associations." It consists of 1,500 such associations subdivided into 26 groups, and its function is to interest itself in all the more important problems of industry and commerce which affect the interests of its members. It may be said to focus the aims of practically the whole of the economic forces of the country.

French State Departmental Organization.—The state commercial departments and offices are chiefly centred round the Ministry of Commerce, to which is assigned the commercial part of the duties fulfilled in England by the Board of Trade This ministry received its present form in 1886. Attached to it is the Conseil Supérieur du Commerce et de l'Industrie, which acts as an advisory council to the minister

Contemporaneous with the commercial intelligence department of the Board of Trade, and founded with the corresponding object of promoting French export trade, the Office National du Commerce Extérieur was established by a law of the 4th of March 1898, and carried on jointly by the Ministry of Commerce and the chamber of commerce of Paris, the latter having provided it with an installation at a cost of over 1,200,000 francs

Since the war the French Government has replaced the Office National by the department of Overseas Trade, which also follows in large measure the lines on which the British department of that name is constructed and works. There are, similarly, numerous commercial attachés in foreign countries to co-operate with it, and to advise it a committee of foreign trade experts chosen from among exporters in France and French merchants abroad The French consular service is also of course charged with the duty of providing such information and general assistance as may be requisite for the promotion of French trade.

A new organ of Government for the perfection of the French economic system was instituted in 1924 in the shape of the Superior Consultative Commerce Committee which includes in its 68 members, besides senators and deputies, representatives of the chambers of commerce and of the more important trade associations It is appointed as to the great majority of its members by the Ministry of Commerce. The sphere of activity of this body embraces commerce, industry and economic organization.

In France the series of trade fairs began in Paris with that of 1904; in 1917 it was resumed after some interruption on a larger scale with the support of 36 chambers of commerce, of 140 trade associations and of the French Government. Organized on a business footing to serve French industry it receives financial support from the Paris chamber of commerce. In 1925 this Paris Fair assumed an international aspect since British, Belgian and other foreign exhibits were included.

The annual fairs at Lyons, commencing in 1916, have always been international in scope; in those inaugurated in the same year, at Bordeaux, French colonial products are predominant, but the fair became international in 1926.

The representation of French production at foreign exhibitions is effected under the guidance and supervision of a permanent foreign fairs committee of the French department of Overseas Trade, and much importance is attached by the French Government to such methods of promoting French export trade.

V. TRADE ORGANIZATION IN GERMANY

Commercial Associations.—In Germany there are two kinds of trade organizations:—

(1) Official organizations established by law, *i.e.*, officially recognised, public legal bodies, the chambers of industry and commerce.
(2) "Free" associations and unions, *i.e.*, unofficial unions.

An intermediate class, the so-called semi-official bodies, dating back to the 18th or beginning of the 19th century, and recognised or even instituted by the Governments of the day, always preserved their official character down to recent times, but have now either been converted into chambers of industry and commerce or ceased to exist. Such are the "Aeltcste der Kaufmannschaft zu Berlin" (established 1820), the "Kommerz-Deputation in Hamburg," the "Handelszunft in Mannheim" (established 1728); the "Handelsvorstände" in Frankfort-on-Main (established 1707), Leipzig, and Cologne, the Merchants' corporations in Stettin, Danzig, Memel, Tilsit, Königsberg, Elbing and Magdeburg (these last dating from the years 1821–25).

Chambers of commerce in Germany (since 1920 almost all called chambers of industry and commerce, in order to denote the equal representation of industry and commerce) show little uniformity, especially as regards historical development, which varied widely in the various states, according to economic and political circumstances. In certain parts of Germany their foreign origin may be easily discerned, while in other parts, as in the Hansa towns, in south Germany (*e g.*, in Nuremberg, Heilbronn, Mannheim), their origin dates back to the private initiative of local merchant circles at the end of the 17th century. Shortly after 1800, chambers of commerce and industry were set up by Napoleon in many towns in the Rhineland territories then ceded to France (*e g.*, Aachen, Eupen, Trier, Krefeld, Mainz). In 1830 a royal statute brought into being a large number of chambers in the rest of Prussian territory.

It was not, however, until 1848 that chambers of commerce in *Prussia* received their first legal status in virtue of a Royal Ordinance When in 1870 a new law re-organized the whole system of chambers of commerce, 33 new chambers had already been established under the first royal ordinance The law of 1870 is still in force, though with many modifications, the most important of which were made in 1897; in *Bavaria* the first ordinance was issued in 1842, and a complete revision was made by the law of Feb. 1908 In *Württemberg* the first ordinance of 1854 was replaced by a law of 1897, which organized the chambers of commerce system on the lines followed in Prussia. In *Saxony* the provisions of the industrial ordinances of 1861 and 1920 apply; in *Baden* the Law of Dec. 1878, with various amendments

In the course of this development the variations in the organization and functions of chambers of commerce as between the various German States have largely disappeared. The following description may be regarded as applying to all chambers of commerce in Germany. They are more autonomous and independent than French chambers of commerce. They have indeed an official character, but are not a corporate part of Government organization. Subject to the provisions of the relevant laws, the chambers fix their own constitution and determine election procedure. Members are freely chosen, and they are quite free as to what resolutions they pass.

The chambers' activities may be divided into two groups:—

(1) Duties imposed on them by State laws; these include drawing up an annual report on the economic position and development in the preceding year, giving advice to officials in questions touching trade and industry, nominating and swearing-in publicly appointed experts, weighers and assessors, and assisting the courts in keeping the commercial register.

(2) Voluntary duties undertaken by the chambers as falling within their scope, *e g*, giving information in questions of customs and transport or home and foreign trade, information regarding trade practice, setting up and conducting commercial schools, administering exchanges, harbours, public and customs warehouses, instituting arbitration courts, and issuing periodical announcements.

To meet expenses the chambers of commerce in Prussia and Württemberg levy a surtax on the industrial tax on profit and capital, to which trade and industry is subject. In Baden a surtax is levied on the income tax and corporation tax. In Bavaria a special tax is levied. In addition, very many chambers of commerce have an individual income from fees for certificates of origin and other attested documents, from exchange and market fees, from receipts for rent of space in the buildings belonging to them. They receive no contributions from the State.

In order better to carry out their duties, the members and constituent firms are divided into three groups (industrial, wholesale and retail), each of which considers matters specially affecting it. Special committees composed of members and non-members exist for separate branches of trade, where necessary.

All chambers of industry and commerce in Germany are united in a central organization in Berlin (the Deutsche Industrie und Handelstag, founded 1861). Further, the chambers of the various States have their own special central organization, and besides this many chambers in the larger districts have united into associations (*Verbände*) for the purpose of pursuing common interests and duties. The following are some examples: Lower Saxon Association of Chambers of Industry and Commerce, Cassel, the Association of Hesse—Nassau Chambers of Commerce and Industry, Association of North-East German Chambers of Industry and Commerce, Association of Central German Chambers of Industry and Commerce, Association of Chambers of Industry and Commerce of the Lower Rhenish and Westphalian Industrial District, etc.

Among individual chambers of commerce, the following may be mentioned:—

(1) *Chamber of Industry and Commerce, Berlin,* founded in 1902, united in 1919 with the Potsdam chamber of commerce and in 1920 with the "Aelteste der Kaufmannschaft," Berlin, which, as stated above, dated from 1820. Its membership amounts to 93. The income amounted in the financial year 1926–27 to approximately 6,616,000 Reichsmarks and the expenditure to approximately 6,177,000 Reichsmarks. The chamber has a retail trade committee and 48 special committees It conducts the Berlin exchange, a commercial high school and various commercial schools.

(2) *Hamburg, Bremen and Lubeck Chambers of Industry and Commerce.*—The chambers of commerce of the Hansa towns possess a special status, both on account of their historical development and on account of their legal status in general. Here by a process of continuous development the chambers of commerce grew out of the early existing corporations.

Thus in Hamburg, the chamber of commerce, instituted in 1867 represents the long established Union of Merchants engaged in land and sea borne trade, the "Versammlung eines Ehrbaren Kaufmanns." At the same time it absorbed the former representative body the "Kommerz-Deputation," which had existed from 1665 to 1867. The chamber was re-organized by a law of 1909 It consists of 34 members, elected by the above-mentioned *Versammlung*. All wholesale merchants established in Hamburg who, on application, are entered on a register kept by the chamber of commerce are members of this union. An "Industrie Kommission" is annexed to the chamber, consisting of 10 members of the chamber and 22 representatives of industry, and deals with industrial questions. The Hamburg chamber of industry and commerce administers the local stock and produce exchange It is officially represented by three members in the "Deputation" for commerce, shipping and industry, annexed to the "Burgerschaft" (lower house of representatives), in the "Deputation" for indirect taxes and duties and in the emigration authority. Its income is derived partly from fees levied for the use of the exchange and its institutions, and from a special tax levied on all firms entered in the commercial register. Its budget closed in 1927 with receipts at 1,673,000 marks and expenditure of 1,197,000 marks The yearly budget must be laid before the Deputation for trade, shipping and industry for information.

The Hamburg retail trade is also legally represented by a "Detaillistenkammer."

The Bremen chamber of commerce (established in 1849 and reorganized by the law of July 1921) consists of 30 members elected by the members of the "Kaufmanns-Konvent" The chamber is officially represented in a mixed committee of members

of the senate and the chamber for the consideration of questions affecting trade and shipping. It is also represented in certain municipal committees including one for promoting trade.

The Lübeck chamber of commerce consists of 21 members who are elected by the "Kaufmannschaft von Lubeck"; it was established in 1867 and its composition and functions regulated afresh by the Merchants Ordinance of 1898 The Lubeck "Kaufmannschaft" is one of the oldest merchant bodies in Germany. Its duties were practically the same as those of the other Hansa chambers of commerce. The chamber carries on its duties in close touch with the senate through various committees consisting of members of the senate and of the chamber, in respect of all questions of trade and shipping The retail trade is also officially represented in Lübeck by a "Detaillistenkammer"

German Chambers of Commerce Abroad.—Especially in the decade 1919–29, German chambers of commerce abroad have been greatly extended Although they are unofficial associations, they are generally officially recognized At the present time (1928) there are about 26 German chambers or mixed chambers consisting of an equal number of German and foreign members. Among these may be specially mentioned those for Switzerland, Spain and Italy and that in Vienna; there are several German chambers of commerce in China and Japan (Shanghai, Tientsin, Canton, Mukden, Tokio, etc) and in South America (Brazil, Uruguay, Argentina)

Voluntary Associations.—A great development has taken place since the war in regard to such associations, both industry and commerce forming numerous societies and unions for the furtherance of their interests The chief organization for the whole of German industry is the Federation of German Industries ("Reichsverband der Deutschen Industrie"), which was established in Feb 1919, and embraces all branches of German industry It is divided into numerous branch groups, each of which is composed of numerous special or technical associations Either individual firms or associations may be members of the federation. Wholesale trade and retail trade are united in a central association, the Central Association of German Wholesale and Retail Trade ("Zentral Verband des Deutschen Gross- und Einzelhandels") with local branch associations all over Germany.

The "Aussenhandelsverband" must also be mentioned as the association for export trade and export industry

German Government and State Authorities and Trade Organisation.—The Ministry for Economic Affairs (Reichswirtschaftministerium) is the competent body for dealing with commercial and industrial questions affecting the whole country Questions of foreign trade, especially commercial treaty negotiations, and consular affairs, are dealt with by the Ministry for Foreign Affairs (Reichsministerium des Aeussern) in conjunction with the Ministry for Economic Affairs

An advisory body also exists, in virtue of Art 165 of the German constitution, in the economic council of the Reich (Reichswirtschaftsrat) It consists of 326 members, but under a bill to regulate its composition it is proposed (1928) to reduce the membership to about 140 to 170. It is divided into 11 committees, the most important being the political-economic committee, the social-economic committee and the financial committee. It approves all important bills on economic and social questions, and the Government is bound to submit such bills to the council before they are laid before the Reichstag The council may also make proposals on its own initiative

In addition each State has a Board of Trade ("Handels-ministerium") for matters affecting trade, industry and production and, like the Government of the Reich, they have a State economic council as an advisory economic body.

Consular and Foreign Trade Service.—All German legations, embassies, consulates-general and the more important consulates have commercial departments attached to them for the promotion and assistance of trade and industry A central information bureau has been set up, to give information to German trade and industry on general economic conditions abroad, on customs and transport questions, import conditions and other subjects. This bureau has branches all over Germany, notably in the more important chambers of commerce.

VI. TRADE ORGANIZATION IN ITALY

Chambers of Commerce.—The Italian chambers of commerce which were regulated by the law of 1862 and performed functions similar to those of the French chambers of commerce, were replaced by Laws Nos. 1045/731 of April 18, 1926, and Nos. 1363/1071 of June 16, 1927, which set up in their place economic provincial councils, "Consigli Provinciali dell' Economia" These councils which commenced their functions as from Dec. 1, 1927, are consultative bodies of the State and local administrations as well as organs for decentralization and for the local execution of Government policy. They are under the general control of the minister of national economy at Rome They formulate proposals for economic development in their province (including agricultural and technical education). They compile and review commercial usages and exercise a general supervision over public institutions concerned with economic matters

They administer the commercial bourses, and through a board which is established in the chief town of the province exercise specific administrative or executive functions in regard to the following matters:—(*a*) representation of the minister of national economy in actions for fraud in trade, (*b*) the laws relating to factory plans and trade marks; (*c*) the registration and winding up of companies, (*d*) the issue of certificates of origin and identity papers for commercial travellers, (*e*) the compilation of bulletins and lists of prices as required under article 38 of the Italian commercial code.

These councils consist of not less than 12 and not more than 28 members, some of whom are *ex officio* members representing Government and public institutions, and others are appointed by the minister of national economy or by royal decree to represent economic associations and institutes of agriculture, manufacturers, traders and employees The chairman is the prefect of the province. All industrial and commercial firms have to register with the economic provincial council and the funds of these bodies are derived from charges on the income of these firms and taxes on land and buildings and social insurance premiums

Government Action.—A Law No. 1129/800 dated April 18, 1926, created the Italian national institute for exportation (Instituto Nazionale per l'Esportazione) which was inaugurated on July 18, 1926, with Dr Pirelli as president This institute, which is controlled and financed by the Italian Government but not a part of the regular Italian civil service, consists of a chairman chosen by the ministers for national economy and foreign affairs, and a general council containing representatives of Government departments, Fascist corporations, commercial and industrial bodies and other economic and financial institutions There is also a technical committee appointed by the general council and consisting of 8 of its members. The function of the institute is to develop export trade, to collect and distribute commercial intelligence and to undertake propaganda work abroad It also arranges for Italian participation in foreign exhibitions and fairs, and assists in the obtaining of credits and proper transport facilities for export trade; in addition it sees to the juridical protection of Italian exporters abroad. It receives a Government contribution of 4,000,000 lire per annum It replaces the commercial information bureau and *Bulletin* of commercial information which had been set up by royal decree No 2125 of Sept 6, 1923.

Bibliography.—*Reports* of Chambers of Commerce; *Reports* of H M Trade Commissioners, Commercial Diplomatic Officers and Consular Officers Abroad; *The Board of Trade* by Sir Hubert Lewellyn Smith, G C B (1928, Ch IV. on Commerce); J. G Smith, *Organised Produce Markets* (1922); *Trade Association Activities*, published by the United States Department of Commerce (1927). (E J. E.)

Russia.—Trade organization in Soviet Russia naturally differs substantially from that of other countries. Centralization in State hands of the ownership of the greater part of industry and of transport of course makes much of the usual commercial machinery inappropriate or unnecessary Of large scale industry 90·7% is owned by the State; 6·8% by the co-operators; and only 2·5%, including concession enterprises, is in private hands. The percentage of production from private industries rises to

26% if the small scale industries and small workshops are included

In the nationalized industries the unit of organization is the Trust which is responsible for a single factory or a group of factories conveniently situated, geographically or commercially, for economical management Each Trust is an independent financial and commercial enterprise with a responsible Board of Directors, with its own capital and credit resources and its own responsibility and incentive for successful commercial operations The State holds the ordinary capital, but the Trusts make their own arrangements for loans and credits with the banks and those with whom they trade The Directors of each Trust are appointed in consultation with the Council of Trade Unions by the Supreme Council of National Economy—the Government Department responsible for the conduct and control of industry The number of Trusts in industries varies In textiles, for example, there are 22 important Trusts; in oil, the most important are the Azerbaijan, Grozny and Emba Trusts, each of which controls the productive and refining process of a whole oilfield

Whilst each Trust has the right of individual trade, in general the Trusts in each industry are linked together in Syndicates for their main buying and selling operations, particularly where they are operating on foreign markets These syndicates are independent financial and commercial units, their share capital being subscribed by the constituent Trusts Among the best known are the Naphtha Syndicate, which disposes of most of the oil products, and the Textile Syndicate, which sells finished goods and buys raw materials on behalf of the textile industry In some cases syndicates have been formed specially for work on foreign markets, e g, Exportles, which acts as the exporting agency for all the Timber Trusts, and Exportkhleb, which has the monopoly of the sale abroad of grain on behalf of the various Co-operatives and Government organizations concerned

The wholesale and retail distributive trades and the marketing of the peasants' produce together with the bakeries, dairies, elevators, cold stores, etc , necessary thereto are mostly in the hands of the co-operatives (*See* RUSSIAN CO-OPERATIVE ORGANIZATIONS) These buy their supplies of industrial commodities from the Trusts or Syndicates concerned

Internal and Foreign trade is under the administrative control of the People's Commissariat of Trade (Narcomtorg) which deals with the adjustment of relations between producers and consumers, and itself decides on prices and other matters of difficulty when negotiations fail It also administers the monopoly of foreign trade, issuing licences for import and export, and appoints Trade Delegations abroad which control the Government and co-operative foreign buying and selling agencies The Gosplan, or State Planning Department, works in close contact with the Supreme Council of National Economy and Narcomtorg It is a statistical and intelligence bureau, whose task is to collect and correlate statistical data and to work out comprehensive operation plans by which industrial and agricultural production, finance and banking, internal and external trade may be developed and correlated.

In the cities there are Goods Exchanges and in the country towns there are markets and fairs at which State trading organizations, Co-operatives, private traders and individual peasants meet for buying and selling. In August of each year there is also held the historic Nijni-Novgorod Fair to which buyers and sellers come from all parts of Russia as well as from Persia, Mongolia and other Asiatic countries. (E. F. WI.)

TRADE ROUTES. In Mediaeval English the word "trade" meant a path; it was connected with the word "tread" Exchange, which is now of the essence of trade, was not at first implicit in the word, but rather the idea of movement to and fro. In a sense trade routes are older than trade. Many of them probably began as "raid-routes." The Norse pirates, for instance, sallied forth annually in the spring by familiar courses and in the autumn returned with their ships laden with spoil The pathways in Central Africa which guided the European explorers of the 19th century had been organized as a thorough system by the Arab slavers.

Ancient Routes.—The trade routes which now envelop the globe as with a net may be regarded as having grown from the track which at the dawn of recorded history connected Babylonia with Egypt These two lands, while both rich with the agriculture of a river plain, so differed in the details of their civilizations as to offer to each other commodities suitable for exchange The primitive way was, no doubt, north-westward along the bank of the Euphrates and then south-westward along the fertile foot of the Syrian mountains, but that way was early "short circuited" by a direct route across the Syrian desert. The change was effected by the Semitic nomads of the desert, whose wealth was of horses, camels, asses, sheep and goats Periodically they made descents on the borders of the cultivated land, robbing the tillers of the soil, the cattle owners, and compelling the towns to engird themselves with walls In time the nomads discovered that articles of luxury taken as booty from one side of the desert commanded a high price on the other side, and gradually a lucrative system of transport and exchange was substituted for the dangerous practice of raiding The nomads knew the whereabouts of the wells and oases, and jealously guarded their secret. Ultimately, because they held the central position and could concentrate quickly for attack, they conquered and ruled the settled peoples of the encompassing fertile plains, and the desert tracks became the links of empire. Rich cities, taking a toll of the passing traffic in return for sending it forward, arose in the oases, as at Tadmor and the later Palmyra, or where the caravan routes ended at the edge of the cultivated land, as at Damascus.

From the Mesopotamian and Syrian ends of this "desert-ferry" there gradually extended ramifications into Europe and into Asia, in each case with alternative routes by land and by sea Towards Europe a traffic grew up through the country of the Hittites, by the Taurus passes and the upland of Asia Minor, to the Balkan peninsula and the Danube basin, and on into Northern Italy. Troy may have risen to wealth and power on this traffic, and by interfering with a local Greek trade through the Dardanelles may have brought upon herself the war sung by Homer On the other hand a Semitic tribe, the Phoenicians, took to the sea and, with transhipment at Tyre, prolonged the desert route over the waters of the Mediterranean to Carthage and Spain In the opposite direction, towards Asia, a trade was organized through the passes in the Persian Mountains and round the north of the Persian deserts into Turkestan and Hindustan, while shipping from the Indies came up the Persian Gulf

The first great change of routes resulted from the conquest of Egypt by the Greeks under Alexander the Great From the newly-founded Alexandria, which took the place of Tyre, ruined by the war, a water-way led up the Nile to Koptos, which is distant by caravan across the desert only 100 miles from the Red Sea—no more than the breadth of the Isthmus of Suez. According to Herodotus the Egyptians had long before joined the western to the eastern waters by a canal through the Isthmus, but in the time of Alexander this had been abandoned, probably for the reason that the homeward voyage of sailing ships up the northern part of the Red Sea was rendered difficult by a persistent contrary north wind, the local equivalent of the trade wind of the same latitudes in the Atlantic Ocean The Koptos route came out at the coast some 300 miles from the northern end of the Red Sea.

The Greeks celebrated under the name of Hippalus the pilot who first among their mariners made use of the seasonal monsoon winds for the direct passage from the mouth of the Red Sea to the coast of India opposite instead of following the shoreline of Arabia and Baluchistan By the second century after Christ the ocean route to southern China was vaguely known to the Greeks of Alexandria Meanwhile the land route through the heart of Asia had penetrated to Northern China, and silk from that source was finding its way to the Mediterranean through Tyre

Silk was a commodity typical of the then traffic by land, for the cost of animal transport was great and could only be borne by goods occupying little space in proportion to their value, such as gold, silver, precious stones, fine linen, and incense. Within the Mediterranean, however, cargoes of grain to such places as Rome constituted a beginning of sea carriage in bulk. Fragile wares such as the art pottery of Athens were transported to every shore.

Mediaeval Routes.—The greatness of Constantinople during the early middle ages was in part based on a continuance of the land traffic through the Balkan Peninsula and Asia Minor. The Saracen and Moorish fleets had rendered the Mediterranean unsafe, and piracy, which had been suppressed while the Roman empire was efficient, had again become rife. Gradually the sea traffic recovered, being organized afresh by the Italian maritime cities, and the later crusaders, in the 12th and 13th centuries, were carried eastward by the ships of Venice. The fact that at this time a single race, the Arabs, dominated the caravan tracks of the Near East and also the sea ways of the Indian Ocean undoubtedly favoured the development of the trade with the Middle and Far East, although Christendom was excluded from the Eastern seas and had to buy silks and spices of the Muslims at Alexandria and Aleppo. Thus the principal trade of the world in the Middle Ages came to be conducted in two separate compartments, Eastern and Western; the goods went through, but not the men

In Europe the Italian cities, especially Venice and Genoa, undertook the forwarding into the West of the wares of the East The lie of the Italian peninsula south eastward towards the Egyptian and Syrian ends of the desert routes was such as to favour sea transport along the Italian coasts into the heart of the Western world From Northern Italy trains of pack animals carried the goods over the Alpine passes to the Rhine, down which river they were transported in boats to Cologne and the cities of Flanders for distribution over Northern France, England, Northern Germany, and Scandinavia On the return journey furs from the northern forests were a principal article of traffic Important banking houses rose to wealth in the cities of South Germany as well as in Venice by financing merchants along this trade route.

At certain times, and notably under the short-lived Mongol Empire in the 13th and 14th centuries, there were notable revivals of the traffic from the Far East through the heart of Asia, although normally the turmoil of barbarous peoples rendered the passage unsafe and costly. The trans-continental caravan route came out either at Aleppo or at the head of the Sea of Azof. The Venetian traveller, Marco Polo, went in at Acre during the Mongol epoch and travelled safely to Cathay or Northern China. The Genoese, from Constantinople, for a couple of generations in the 14th century did a considerable trade with the East through the Black Sea

Growing Predominance of Sea Routes.—In the 15th century a change in the course of European trade took place which must have appeared even to contemporaries as of the first importance. Venice began to send forward the wares received from the East no longer over the Alps and by the Rhine, but by an annual fleet through the Straits of Gibraltar to Flanders, with a call of some of the ships at Southampton The overland traffic soon yielded to the new competition, and the financial houses of the south German towns transferred themselves to the Netherlands. There had long been a local trade of English wine ships to Bordeaux and the advent of the Italian pilots, now equipped with the mariner's compass, into the outer seas with the valuable wares of the East must have stimulated ideas of bolder venture in the northern ports The exploration of the West coast of Africa, organized from Portugal by the half-English Prince Henry the Navigator, was contemporary with, and no doubt incidental to, this development If sea venture round the West of Europe was cutting out the continental traffic across Europe, why should not a greater venture round the South of Africa cut out the traffic across Egypt and Syria? The spices of the Orient would then reach London by an unbroken voyage with only terminal handling of goods, whereas by Egypt and the Rhine there was a chain of three sea voyages, with two expensive land sections intercalated, and handling of the goods at least six and more often eight or ten times.

During the early 16th century Venice struggled tenaciously to maintain her trade long after Da Gama had rounded the Cape, and the last voyage of the Venetian fleet to England and Flanders did not occur until 1532. The 17th and 18th centuries saw a virtual monopoly of the carriage of the world's trade by the sailing ship on the ocean. Strictly speaking there are no trade routes on the sea. Once the mariner had learnt to go boldly out of sight of land, he was free of all the ocean, and might descend upon any coast. Practically, however, the greater part of the water surface of the globe is left to-day as in the past to the undisturbed possession of the albatross and the flying fish, for merchant craft are compelled for economic reasons to keep to the courses which on a balance of considerations are likely to yield the best net results to their owners. In the great sailing days, however, ship-masters took other courses from those followed in the later days of steam, and courses, moreover, which varied in most cases on the outward and homeward voyages. In the Atlantic the trade winds, north-east and south-east, determined the sailing tracks, and the Gambia became a place of refreshment on the outward voyage and St. Helena on the homeward voyage. Algoa and Delagoa are names which record corresponding facts with reference to the voyages of the Portuguese to and from Goa on the seasonal monsoon winds. Thus the new ocean routes to the Indies came to be punctuated with victualling and watering stations and these stations were the property of the "East India Companies" of the several nations

At first the Portuguese claimed an exclusive use of the new route which they had discovered to the East, and "stapled" the goods which their ships brought home at Lisbon, and other peoples had to come and buy there. This "pride of the wholesaler" brought its retribution, for the Dutch built up a distributing trade from Lisbon throughout northern Europe, and when Portugal was conquered by Spain, the Dutch rebels against Spain steered past Lisbon and sought their own wares in the East. Amsterdam now became the seat of the depôt trade in spices, a term which covered many more articles than in modern parlance It would exceed the limits of this article to enter into the history of the English and French competition with the Dutch on the trade route to the Indies. Suffice it to say that England ended by defeating all her rivals, in no small measure because her motive was to sell even more than to buy.

Europe and the Indies.—The history of human civilization might be written round the story of the trade routes between Europe and the Indies The facts of physical geography are such that it was inevitable that the main trade of the world, apart from local exchanges, should be between the northwest and the south-east of the Euro-Asiatic continent Those two regions are alike characterized by ample rainfall, lowland soils, and navigable rivers and arms of the sea. They are separated by a belt of great deserts through which lie narrow natural ways, such as the Red Sea and the Nile and Euphrates rivers. Neither the north of Asia nor the centre and south of Africa offered comparable facilities for early human development. To-day, on an area of some three million square miles in Europe are three hundred million people, and on an area of some five million square miles between Ceylon and Japan are eight hundred million people

Europe and America.—The second great trade of the world, that between Europe and America, was inaugurated by the voyages of Columbus. He set out to reach the East by way of the West, and as a fact his immediate successors succeeded in accomplishing that feat. The Philippine Islands were approached by the Spaniards, not by the Portuguese route round the Cape, but across the Pacific The track of their galleons was from Spain to Vera Cruz in Mexico, and thence the way led over the Mexican table-land to Acapulco on the Pacific shore, and then by ship across the Pacific. Thus at the very time when trade was abandoning the overland routes in Europe and the Near East, a new overland route was established in America. The reason, apart from the opposition of the Portuguese, was that America projects 20° of latitude farther south than does Africa, and the passage into the Pacific by doubling Cape Horn is a far more serious venture than the rounding of the Cape of Good Hope into the Indian Ocean.

The sailing track from Europe to America was on the north-east trade wind to the tropical West Indies, whence shipping turned northward to Virginia and so homeward on the prevalent west winds of the higher latitudes—a great triangle of trade. Only Canada and New England were reached laboriously by tacking against the west winds. In no trade in the world has the advent of steamships been of greater assistance than in the North Atlantic. Elsewhere on favouring winds a sailing ship would often

make nearly as quick a passage as a steamer

The Advent of Steam Power.—The Industrial Revolution of the later 18th and early 19th centuries, though it transformed manufacturing, wrought comparatively little change in commerce. The commercial revolution began only about 1870. In that year only about 10% of the world's shipping was moved by steam; today not 10% is moved by sails. The newly-made roads and canals, and at first even the railways, remained subsidiary to ocean traffic. There was, however, one freshwater canal the construction of which effected changes on a world scale The opening of the Erie Canal in 1825 from the great lakes of North America to the Hudson River and the Atlantic brought the harvests of the west into relation with the industrial coastland of New England New York, which had hitherto been a smaller place than either Boston or Philadelphia, shot forward in development to become as is now inevitable the largest city in the world Today 130 million highly civilized people in the United States and Canada offer as great a basis for international trade as the 800 millions of the Orient, and the North Atlantic trade route balances in importance the ways of the east.

The first transcontinental railway from Atlantic to Pacific was completed through the United States in 1867, but the day of transcontinental carriage of goods in bulk did not begin until about 1878, when for the first time the grain of the prairies was brought to England

Modern Developments.—Much more immediately significant was the opening in 1869 of the Suez Canal (*q v*) A large part of the ocean-borne commerce to the East was almost at once diverted to the new route The approach to India, which round the Cape was as easy to Calcutta as to Bombay, was now more direct to Bombay, and thence the railways of India were constructed southeastward, eastward and north-eastward, radially from the terminus of the new ocean-ferry from Europe Simultaneously the piercing of the Alps by railway tunnels, of which the first, the Mont Cenis, was completed during the Franco-Prussian War in 1870, facilitated the transfer of the European points of departure for India to the Mediterranean ports Italian Genoa became the principal southern exit for German commerce, and even British liners had to call at Marseilles

Towards the end of the 19th century the railway net began to cover wide areas on the continents, and for some purposes land transport seemed likely to rival sea transport. Transcontinental railways now traverse Asia, Australia and South America, and it is only a question of time before the Cape to Cairo line, the dream of Cecil Rhodes, will be realized None the less for the carriage of bulk the sea holds its own The tonnage through Panama already exceeds that through Suez, although the completion of the second interoceanic canal has not affected a change in trade routes at all comparable with that which so quickly ensued on the opening of the first.

Air Routes.—To-day, 1929, the commerce of the world is on the verge of yet another change. Air routes are being added to land routes and sea routes At first sight it would appear that there can be even less of a route in the air than on the sea. In fact, air craft are very closely dependent on their prepared landing places. One of the most interesting services of aeroplanes as yet in operation is that from Egypt to 'Iraq, along the most ancient of all routes. Great airships are building, 700 feet long, which will float in the wind when tethered to mooring towers like sea ships anchored in a current; these are expected to make the voyage from Great Britain to Karachi, the airport at the entry to India, in 4 days with a call at the mooring tower on the Suez Canal.

Two things are clear. Air traffic will supplement and not supplant the older means of carriage, for the lifting capacity of an airship of 5 million cubic feet gas capacity is only 150 tons; and the capital which is being sunk at the new airports will tend to fix the more important air routes. In regard, also, to the lie of those routes there are two things which may be said with some certainty. The first is that the courses followed by aircraft will for economic reasons have regard to the prevalent winds and will approximate rather to the sailing than to the steaming tracks of surface vessels It is not improbable that, when experience has brought courage, the airship track from Great Britain to Australia will run southward to South Africa and then eastward on the great west winds of the "Roaring Forties" of the Indian Ocean The second is that similar economic considerations must limit the height at which commercial aircraft will fly; there will be an "economic height" just as steamers and motor vessels have an "economic speed." That height will be such as to retain the maximum lifting capacity compatible with a safe margin for manoeuvring. Thus aircraft will respect the major elevations of the land, just as surface vessels seek to avoid rocks and shoals It is probable, for instance, that airships from Great Britain will commonly pass southward through the gap at Marseilles between the Alps and the Pyrenees.

The tendency of the trade routes of to-day—by land, sea, and air—is to exhibit on the map the appearance of a net Within the limits set by the consideration that goods are carried most cheaply in reasonable bulk, transport now seeks the direct line from the place of production to the place of consumption Thus the "depot" trade, associated in the past with such "nodal" centres as Alexandria, Venice, Lisbon and Amsterdam, and of late with London, is not increasing. But the brain centres, the centres of the higher control of exchange, are if anything becoming fewer

BIBLIOGRAPHY —Information in regard to the trade routes of the past is to be found scattered through books on general and commercial history; there are very few works specially devoted to the subject *See* O. Noel, *Histoire du Commerce du Monde*, 2 vols (1891 etc), with a useful bibliography, H de B Gibbins, *History of Commerce in Europe* (1891); E Speck, Handelsgeschichte des Alterthums, 3 vol (1901–06); E H Warmington, *The Commerce between the Roman Empire and India* (1928). The history of trade routes is closely involved in that of geographical discovery; *see* E H. Bunbury, *History of Ancient Geography* (1879) and H Yule, *Marco Polo* (3rd ed 1903) *See* also Russell Smith, *The Ocean Carrier* (1908); A. J. Sargent, *Seaways of the Empire* (1918). (H. J. MA.)

TRADES UNION CONGRESS, THE. The Trades Union congress came into existence in Great Britain when the Manchester and Salford trades council convened a trades union conference in Manchester in Whit-week 1868 There were earlier national conferences, but the Trades Union congress itself dates its birth from the gathering at Manchester of 34 delegates representing 118,367 members of unions In 1869 a parliamentary committee was appointed to carry out the decisions of the congress. In its early days, the congress was concerned largely with trade union legislation It was not long before it was considering political questions, though for years the "economist" or *laissez faire* school held their own against the more advanced school In 1882 the congress adopted by 71 to 31 votes a resolution in favour of land nationalisation, but in later years a similar resolution was rejected. In 1888, however, the principle was decisively endorsed by 66 to 5 votes It was not until 1885 that the principle of the legal regulation of hours of labour was adopted by the Trades Union congress, and in 1890 it carried a resolution in favour of an Eight Hours Bill By this time, it may be said, the congress had finally repudiated economic individualism and embraced the Socialist philosophy, and before many years passed it had created the Labour Party. As early as 1869 a paper dealing with direct labour representation in parliament was read at the T U C. In 1886 it appointed a labour electoral committee which, however, came under Liberal influence, and in 1893 it ceased to operate. In 1899 a resolution was carried for a special congress of trade unions and Socialist organizations. The result was the inauguration of the Labour Representation Committee, and the birth of an independent political labour movement.

The influence of the congress grew with the increase in trade union membership. But it was the World War which laid the foundations of its present prestige. The decision of the congress to take part in the war-time administration of the nation marks an important stage in its history. The congress emerged from the war with greatly increased membership and authority

General Council Organization.—In 1919, therefore, proposals were submitted to a special Trades Union congress for the replacement of the old parliamentary committee of the congress by an enlarged executive body, for the creation of a machinery of co-operation between the congress and the Labour Party, and for

the establishment of joint administrative departments under the auspices of the congress and the Labour Party. The parliamentary committee was superseded by the general council, a body composed of 32 members representing the 17 groups of trades and industries into which the affiliated membership of the congress was divided, including two women representing the woman membership of the Trades Union congress

The following table shows the organization of the council

	Trade group	No of unions	Membership (1928)
1.	Mining and quarrying	8	759,611
2	Railways	3	423,806
3.	Transport (other than railways)	8	389,571
4	Shipbuilding	3	77,911
5	Engineering, founding and vehicle building	25	329,499
6	Iron and steel and minor metal trades	21	127,626
7.	Building, woodworking and furnishing	17	344,773
8.	Printing and paper	12	135,072
9.	Cotton	37	227,562
10	Textiles (other than cotton)	18	166,923
11.	Clothing	8	88,477
12.	Leather and boot and shoe	5	88,654
13	Glass, pottery, chemicals, food, etc.	16	193,204
14.	Agriculture	1	30,000
15.	Public employees	4	24,651
16.	Non manual workers	6	58,106
17	General workers	4	409,896
	Totals	196	3,874,842

This organization is carried further by the establishment of group committees For administrative purposes the 17 trade groups were formed into six group committees as follows: (a) mining and quarrying, railways, transport, (b) shipbuilding, engineering, iron and steel, building, (c) cotton, other textiles, clothing, leather, (d) glass, pottery, etc, agriculture, general workers; (e) printing, public employees, non-manual workers; (f) the two women members and three members appointed by the general council from organizations with women members.

The congress also accepted in 1920 as did the Labour Party conference of 1921, proposals for the establishment of four joint departments: (*a*) research and information, (*b*) press and publicity; (*c*) international, and (*d*) legal. This new central machinery resulted in a great expansion of activities by the general council of the T U C itself and by the council in conjunction with the political labour movement In 1925 the general council reported to the congress that the rapid expansion of work necessitated separate machinery, and on March 31, 1926 the joint departments ceased to exist The administrative side of the T U C. has now departments dealing with organization, trade boards, research, publicity, social insurance and international matters.

Council Activities.—The general council of the T U C. deals with a wide range of questions and its authority continues to increase. It has instituted a standing trade boards advisory council, composed of representatives of organizations catering for workers covered by the Trade Boards Acts. It has its education committee which has concerned itself with the problem of adult education, whose proposals, approved by the Trades Union congress in 1925, were designed to assist in the promotion of educational facilities for trade unionists, and had been arrived at in agreement with Ruskin college, the education department of the Co-operative Union, the Labour college, the Workers' Educational Association, and the National Council of Labour colleges. The object of the proposals was "to provide working-class education in order to enable the workers to develop their capacities and to equip them for their trade union, labour and co-operative activities generally, in the work of securing social and industrial emancipation." Early in 1926, the countess of Warwick handed over her estate, Easton lodge, Dunmow, in Essex to the general council of the Trades Union congress for use as a labour college and as a labour centre generally, but owing to the financial obligations involved the scheme did not materialise In 1927 the general council inaugurated a scholarship scheme, which provides three scholarships a year tenable at the Labour college and Ruskin college respectively.

The general council has taken an increasingly important part in large industrial disputes. At the Hull congress of 1924, its hands were strengthened in this matter. In the event of a breakdown of negotiations in a dispute, "the deadlock being of such a character as to directly or indirectly involve other bodies of work-people affiliated to the Trades Union congress in a stoppage of work or to imperil standard wages and hours and conditions of employment, the council may take the initiative by calling representatives of the unions into consultation, and use its influence to effect a just settlement of the difference." Before this resolution was carried, the general council had, in fact, intervened by mediation or the granting of moral and financial support, in disputes in which affiliated societies were concerned In the prolonged boilermakers' dispute in 1924, in the dock workers' dispute, the tramway dispute in the London area, the Southampton shipyard dispute, and the building trade dispute in the same year, the general council used its good offices But the adoption of the resolution of Sept., 1924, placed greater authority in the hands of the council On the occasion of the dispute in the coal industry in July 1925, the general council appointed a special industrial committee and took a very prominent part in the negotiations which led to the temporary settlement The industrial committee in Aug 1925, intervened in the dispute in the wool textile industry which had culminated in a stoppage of work In 1927 it took a hand in the settlement of the packing-case makers' dispute in Leicester, and in 1928 it assisted in the settlement of a dispute between the National Amalgamated Union of Life Assurance Workers and the Wesleyan and General Assurance Society The year 1928 also saw the intervention of the General Council in the dispute on the Nottinghamshire coalfield

In conjunction with the Labour Party and the Miners' Federation of Great Britain the general council established a committee early in 1925 to prepare a policy for the coal industry, and the proposals of this joint committee were submitted to the royal commission on the coal industry set up by the Government after the coal settlement in July 1925 After the publication of the royal commission's report, the general council, through its industrial committee resumed its consultations with the Miners' Federation and was associated closely with the federation during the course of negotiations Finally, it declared a large scale sympathetic strike (commonly called the "general strike" [*q.v*]) and for the first time in its history tried to stop all industry

An important and developing side of the activities of the general council is the forging of closer bonds with the trades and labour councils which exist in large numbers up and down the country Before 1895 trades councils were represented at the annual Trades Union congress But from that date until 1924 there was no direct contact between these local representative bodies of trade union branches and the T U C, though the trades councils (many of which are local Labour Parties) were affiliated to the Labour Party and sent delegates to its annual conferences

After the establishment of the general council, efforts were made to remedy this defect in organization, and in 1925 a model form of constitution for trades councils was worked out, arrangements made for the publication and circulation of special literature on trade unionism, and a regular monthly statement from the general council to the trades councils was inaugurated At the end of 1924, there were 476 trades councils known to be in existence in Britain, including industrial sections of local Labour Parties In 1913 the number was 328. From 1913 to 1924 the aggregate affiliated membership rose from 1,481,000 to 2,219,000, the latter figure representing about two-fifths of the total membership of trade unions. The general council has taken an active part in promoting federations of trades councils Since 1927, it has refused to recognise councils which are affiliated to the National Minority Movement.

Perhaps the most significant amongst the activities of the general council, is its efforts under the instructions of the Trades Union congress to promote and assist trade union amalgamation on the lines of organization by industry. Though the general council has from time to time brought together unions for discussion

of the possibilities of amalgamation, it has realised that much more is needed than empirical action of this kind. Judged by results the efforts to bring about amalgamations the general council cannot be regarded as successful, though it is still too early, having regard to the real difficulties of amalgamation, to pronounce this work as a failure. Its real importance, however, lies in the persistent and painstaking labour to reach an ideal, and the certainty that, if need be, larger powers will ultimately be given to the general council to deal with the problem.

Finance.—Up to 1923, the affiliation fee of each union affiliated to the T.U.C. was 1d per member per year. In that year the fee was raised to 3d, payable quarterly on the full membership, including probationary and free members. The increased fees were required principally for publicity purposes and to maintain the *Daily Herald,* the organ of the British labour movement In addition to the ordinary affiliation fees, each union contributes £1 per thousand members towards the fee payable to the International Federation of Trade Unions Congress affiliation fees in 1926–27 amounted to £27,550. The affiliation fee to the International Federation of Trade Unions was £4,392

The Industrial and the Political Movements.—As the Trades Union congress really gave birth to the Labour Party, it is natural that close relations should always have existed between the industrial and political sides of the labour movement From 1905 onward there existed a joint board representing the parliamentary committee of the T U C, the executive committee of the Labour Party and the management committee of the General Federation of Trades Unions (which like the Labour Party owed its existence to the T U C) The members of the board were the secretary and three members from each of the three bodies. But in 1914 the congress decided to dissolve the tripartite joint board and to establish a new one representing the parliamentary committee of the Trades Union congress and the executive committee of the Labour Party At the congress of 1917 steps were taken to ensure close co-operation between the two committees. Joint meetings take place, and joint action has often been taken

The conference accepted in 1920, as did the Labour Party conference of 1921, proposals for the establishment of a national joint council consisting of the chairman and secretary and three members of the general council of the Trades Union congress, the national executive committee of the Labour Party and the executive committee of the parliamentary party, 15 members in all

Membership of Trade Unions Affiliated to the Trades Union Congress

Year	No. of unions	Total membership*	Year	No. of unions	Total membership
1868		118,367	1898	188	1,184,241
1869	40	250,000	1899	181	1,200,000
1870	49	289,430	1900	184	1,250,000

*From 1868 to 1894 inclusive the figures for total membership were duplicated by the inclusion of Trades Councils.

†There was no Congress in 1914.

**The decrease is almost wholly due to the forcible separation from Congress of the Civil Service Unions under the operation of the Trade Disputes and Trade Unions Act, 1927.

Membership.—The growth which has taken place in the affiliated membership of the congress since its inception may be seen in the table in the preceding column. (A. Gr)

TRADE UNIONS. Efforts have been made to trace the lineal descent of the trade union movement of the 19th and 20th centuries from the gilds of the middle ages But trade unionism as we know it, was the creation of modern industrial conditions It owes its birth to the capitalist system. Viewed after more than a century of growth it is seen in its first phase of development as an instinctive method of self-protection against the reactions of complex economic changes, which the workers, in common with the rest of the nation, failed to understand In its later phase of growth, the trade union movement is seen as a more conscious organisation of labour concerned with the status of the worker and his place in the economic system Trade unionism is a defensive and offensive instrument for maintaining or improving labour standards But it is more than this It is becoming increasingly a constructive agency, aiming at influencing and changing the world of industry in accordance with labour ideals. This constructive purpose of trade unionism is promoted in two main ways,—through the assumption by the organised workers of increasing "control" over working conditions and the conduct of industry, and through the extension of public ownership in the essential industries and services In its activities in the latter direction, British trade unionism is political and is allied with the Labour Party, which it brought into existence

The trade union movement has within the space of a century become an integral part of the machinery of industrial life Since the days when under the repressive legislation of the time, local trade unions existed as secret and illegal bodies, trade unionism has secured for itself well nigh universal recognition from employers and the public But whilst it is generally accepted that the conduct of industrial relations in Great Britain must be on a basis of negotiations between organised workers and organised employers, there is by no means the same degree of unanimity as regards either the part which trade unions should play in the future in the direction of the policy of industry, or the lines on which industry should develop Nevertheless, far-sighted employers realise that trade union organisations must be accorded the fullest possible information as to the economic position of industry and be brought into the discussion of questions of high policy in industry Already, therefore, the door is being opened to the claim of the unions for greater "control" The problem of ownership, however, remains a purely political problem to be solved by political methods

The Combination Laws.—The history of such a movement could not be uneventful. Time was when by the common law of England combinations of workpeople were, with minor exceptions, regarded as illegal They were deemed to be contrary to public policy, and fell into the category of conspiracies in restraint of trade Membership in such a body was punishable by fine and imprisonment, and though strictly the common law applied to combinations of both masters and men, it was against the latter that the law was developed and directed From the time of Edward I to the end of the first quarter of the 19th century there were a series of legal enactments—between 30 and 40 in all—which enforced and extended the common law All these measures were designed to prohibit and prevent labour organization.

The far-reaching industrial changes which marked the second half of the 18th and the beginning of the 19th centuries created a situation which gave a new impetus to the establishment of combinations of workers Notwithstanding the existence of repressive legislation, secret trade societies became more numerous The laws against combinations were made more stringent and more general by the Acts of 1799–1800 which remained unaltered until 1824. In spite of this legislation, which made all combinations illegal, trade clubs seem to have continued to exist and were tolerated in many trades and in many areas during the first quar-

ter of the 19th century, though they were always subject to the fear of prosecution if they took hostile action against employers; and in many cases strikes were suppressed by the conviction of their leaders under these Acts or the common law of conspiracy

In 1824 a select committee of the House of Commons was appointed to enquire, among other matters, into the "combination laws" This committee reported that "those laws had not only not been efficient to prevent combinations either of masters or workmen, but on the contrary had, in the opinion of many of both parties, had a tendency to produce mutual irritation and distrust, and to give a violent character to the combinations, and to render them highly dangerous to the peace of the community" They further reported that in their judgment "masters and workmen should be freed from such restrictions as regards the rate of wages and the hours of working, and be left at perfect liberty to make such agreements as they mutually think proper." They therefore recommended that "the statute laws which interfered in these particulars between masters and workmen should be repealed,' and also that "the common law under which a peaceable meeting of masters or workmen might be prosecuted should be altered" In pursuance of their report, an Act, 5 Geo IV. c. 95, was at once brought in and passed. But the immediate results of the change which it effected were regarded as so inconvenient, formidable and alarming, that in the session of 1825 the House of Commons appointed another select committee to re-examine the various problems, and review and reconsider the evidence submitted to their predecessors They reported without delay in favour of the total repeal of the Act of 1824, and the restoration of those provisions of the combination laws, whether statutory or customary, which it had been more particularly intended to abrogate The consequence was an act passed in 1825 of which the preamble declares that the Act of 1824 had not been found effectual, and that combinations such as it had legalised were "injurious to trade and commerce, dangerous to the tranquility of the country, and especially prejudicial to the interests of all who were concerned in them" The effect of this act was to leave the common law of conspiracy in full force against all combinations in restraint of trade, except such as it expressly exempted from its operation, as it had been before the Act of 1824 was passed. It comprised, however, within itself the whole of the statute law relating to the subject, and under it no persons were liable to punishment for meeting together for the sole purpose of consulting upon and determining the rate of wages or prices which they, being present, would require for their work or pay to their workmen, or the hours for which they would work or require work in any trade or business, or for entering into any agreement, verbal or written, for the purpose of fixing the rate of wages or prices which the parties to it should so receive or pay But all persons were subjected to a maximum punishment of three months' imprisonment with hard labour who should by violence, threats or intimidation, molestation or obstruction, do, or endeavour to do, or aid, abet or assist in doing or endeavouring to do, any of a series of things inconsistent with freedom of contract which the act defined.

Growth of Trade Unionism.—The partial protection accorded to societies for the purpose of regulating wages and hours of labour by the law of 1825 led to a rapid multiplication and expansion of trade unions, and to an outburst of strikes, in which, however, partly owing to the widespread commercial depression, the workmen were mostly unsuccessful Thus the first impetus given to trade unions by the modification of the combination laws was followed by a collapse, which in its turn was followed (in the third decade of the century) by a succession of attempts on the part of workmen to establish a federal or universal combination, to embrace members not of one but of several trades. To this new form of combination which excited a good deal of alarm among employers, the term "trades union" as distinct from trade union, was applied. All these general movements, however, proved shortlived, and the most extensive of them, the "Grand National Consolidated Trades Union," which was formed in 1834 and claimed half a million adherents, only had an active existence for a few months, its break-up being hastened by the conviction and transportation of six Dorchester labourers for the administration of unlawful oaths. In the years of depressed trade which followed, trade unionism once more declined, and the interest of workmen was largely diverted from trade combinations to more general political movements, *e.g.*, Chartism, the Anti-Corn-Law agitation and Robert Owen's or other schemes of co-operation.

From 1845 we trace another revival of trade unions, the characteristic tendency of this period being the amalgamation of local trade clubs to form societies, national in scope, but confined to single or kindred trades High rates of contribution, and the provision of friendly as well as trade benefits, were among the features of the new type of union, of which the Amalgamated Society of Engineers, formed in 1851, was the most important example The growth of unions of the new type was followed by a development of employers' associations in the 'sixties, and by a number of widespread strikes and lock-outs, and also by various efforts to promote arbitration and conciliation by the establishment of joint boards of employers and employed.

A series of outrages at Sheffield and Manchester in 1865–1866, in which officials of some local trade societies were implicated, led to the appointment in 1867 of a royal commission on trade unions, whose report was followed by the passage of the Trade Union Act of 1871, which as amended by subsequent legislation governs the legal position of trade unions.

Trade Union Legislation 1871–6.—In the meantime, legislation was passed in 1859 to remove doubts as to the meaning of "molestation" and "obstruction" The outcome of the royal commission was, first, a temporary measure for the more effectual protection of the funds of trade unions, passed in 1869, and secondly, the two Trade Union Acts of 1871 and 1876

Under these statutes, construed with the Conspiracy and Protection of Property Act, 1875, the law relating to combinations, whether of workmen or of masters, entered upon a new phase

The Act of 1871 laid it down that the purposes of any trade union shall not, by reason merely that they are in restraint of trade, (*a*) be deemed to be unlawful, so as to render any member of such trade union liable to criminal prosecution for conspiracy or otherwise, and (*b*) be unlawful so as to render void or voidable any agreement or trust It further enacted that certain trade union contracts shall not be enforceable by the courts, *e.g.*, any agreement for the payment by any person of a subscription or penalty to a trade union, and any agreement to provide benefits to members The act also made provision for the registration of trade unions, and for the purchase or lease of buildings by trade unions The Trade Union Act of 1876 amended the law of 1871 on matters of minor administration, and provided for the amalgamation of unions It altered the definition of trade union

The Conspiracy and Protection of Property Act, 1875 superseded the Criminal Law Amendment Act of 1871 which had been opposed by the trade unions and which had proved to be an instrument of coercion It laid down that an agreement or combination by two or more persons to do or procure to be done any act in contemplation or furtherance of a trade dispute should not be indictable as a conspiracy if such act committed by one person would not be punishable as a crime. The act legalised peaceful picketing and cases of intimidation or violence were to be left to the courts of summary jurisdiction.

The "New Unionism."—The period of inflated trade which began in 1871 caused as usual, another rapid growth of trade unions, of which the most characteristic feature was their extension to agricultural and general labourers. The years of depression, 1875–1880, were marked by a series of unsuccessful strikes against reductions of wages, and by a general decline of trade unions, which did not again revive until nearly ten years later, when the new wave of prosperous trade brought with it an outburst of strikes, chiefly among unskilled labourers, for improved conditions, of which the most notable was the strike of the London dock labourers in 1889. These trade movements were accompanied by the formation of a large number of unions of a type more akin to those of 1830–1834 than to the more modern trade-friendly society with its high contributions and benefits

The nineties also saw the spread of trade unionism to the black-coated workers. The National Union of Clerks came into

existence in 1890, followed shortly by the Shop Assistants' Union and the Amalgamated Union of Co-operative Employees

Trade Union Membership, 1892-1913

Year	Number of trade unions at end of year	Membership at end of year			Percentage increase (+) or decrease (−) on total membership of previous year
		Males	Females	Total	
		Thousands	Thousands	Thousands	Per cent
1892	1,233	Not available		1,576

1911	1,290	2,804	335	3,139	+22·4
1912	1,252	3,026	390	3,416	+ 8·8
1913	1,269	3,702	433	4,135	+21·0

From 1892 onwards the progress of trade unionism can be traced statistically (*see* the table) The depression of trade, 1892–1895, brought with it, as usual, some decline in trade unionism; but though many of the "new unions" collapsed, some of the more important have survived to the present time. The revival of trade which began in 1896 was naturally accompanied by an increase in the strength of trade unions; but the most marked characteristic of this period was the extension and consolidation of employers' associations, of which perhaps the most notable is the Engineering Employers' Federation, which was originally formed on the Clyde, but gradually extended to other districts and became a national organisation of great strength during its successful struggle with the Amalgamated Society of Engineers in 1897–1898 Among the other more important Employers' Associations and federations of a national character may be mentioned the Shipping Federation, the Mining Association, the Shipbuilding Federation, the Federation of Master Cotton-Spinners' Associations, the National Federation of Building Trade Employers, and the Incorporated Federated Associations of Boot and Shoe Manufacturers

At the beginning of the 20th century the trade union movement was fairly established The local trade clubs had given way to national organisations of considerable size and unions existed for practically every type of worker. The opening years of the century prior to the outbreak of the World War saw a considerable expansion of trade unionism. The number of trade unionists doubled between 1900 and 1913

The Taff Vale Decision.—During the last quarter of the 19th century there were many cases in the law courts affecting trade unionism, but by far the most important was the Taff Vale case. This famous case which was largely responsible for the rapid growth of the Labour Party arose out of a local dispute, when in 1900 railway workers employed by the Taff Vale Railway Company in South Wales came out on strike without any authority from their union—the Amalgamated Society of Railway Servants. The introduction of blacklegs by the management brought the A.S R.S. officially into the arena. The society granted strike pay to the strikers, and did its best to dissuade the blacklegs from continuing at work The strikers undertook picketing, and there was some violence, for which, however, the society was in no way responsible. It neither instigated nor authorised violence. The company, besides prosecuting individual employees, took legal action against the A.S.R.S. itself. In the first place, it brought an action for damages against the society, and in the second place it sought an injunction to restrain the union and its officers from committing acts calculated to damage the company in its business. Both actions were successful. The A S.R S paid out damages amounting to £23,000 and the injunction was granted The case ultimately reached the House of Lords, and in 1901 the Lords upheld the original decision of the court. The decision descended like a thunderbolt on the whole trade union movement.

The trade unions and the Labour Party, which the Trades Union congress had brought into existence in 1899, vigorously protested against the result as a decision of judges making a practically new law against trade unions and nullifying the settlement of their status made by the legislature in 1871, and in June 1903 a royal commission was appointed to inquire into the subject of trade disputes and trade combinations

The majority of the commission reported in Jan. 1906, in favour of an alteration in the law relating to picketing and conspiracy, but against any alteration of the law as laid down in the Taff Vale judgment Under pressure from the Labour Party, the Government of the day did not accept this conclusion, and a different view was embodied in the Trade Disputes Act passed in the same year. It was enacted with reference to trade union funds that "an action against a trade union, whether of workmen or masters, or against any members or officials thereof on behalf of themselves and all other members of the trade union in respect of any tortious act alleged to have been committed by or on behalf of the trade union, shall not be entertained by any court," although "nothing in this section shall affect the liability of the trustees of a trade union to be sued in the events provided for by the Trades Union Act, 1871, section 9, except in respect of any tortious act committed by or on behalf of the union in contemplation or in furtherance of a trade dispute "

The Osborne Judgment.—This victory for the trade unions was speedily followed by another attack The Amalgamated Society of Railway Servants again bore the brunt of the struggle In 1908 W. V Osborne, a branch Secretary of the A S R S., sued the society to have it declared that one of its current rules, which provided, amongst other things, for parliamentary representation and the enforced levy of contributions from him and other members of the society, towards the payment of salaries or maintenance allowance to members of parliament pledged to observe and fulfil the conditions imposed by the Labour Party, was *ultra vires* and void. The case was decided in the King's Bench against Osborne, but the judgment was reversed by the court of appeal, whose decision was upheld by the House of Lords on Dec 21, 1909. This meant that the Labour Party in the House of Commons would have to find other ways and means than contributions from trade unionists.

The labour movement turned its energies to the reversal of the Osborne judgment The Labour Party abolished the pledge referred to above, and when the payment of members was introduced—a measure which was largely a direct result of the Osborne judgment—it discontinued the payment of allowances to elected Labour candidates. After the elections of 1910 the Labour Party demanded legislation, but it was not until 1913 that compromise was reached in the Trade Union Act of that year. This measure permitted political action and enabled unions to carry on any lawful activity which was authorized by its rules But the law imposed certain restrictions on the political activities of the unions. A trade union which wished to engage in political activities was required to take a ballot of its members and to obtain a majority of those voting in favour of such action The union, after a successful ballot, had then to draw up political rules, in a form approved by the chief registrar of friendly societies. A separate political fund was to be established from which all expenditure on political purposes as defined by the Act was to be met. Lastly, any member of the union who objected to the political levy was, on signing an approved statement, to be exempted from all political contributions without forfeiting his rights as a member of the organisation.

Industrial Unrest.—In the meantime, whilst the mind of the trade union movement was exercised by the Taff Vale and Osborne decisions, there was a growing volume of industrial unrest. Prices had for some time been rising, and real wages were falling Trade unionism was stronger than ever it had been, but it held back from action in view of the Taff Vale decision After the passage of the Act of 1906, however, many strikes broke out There was in 1907 a prolonged dispute on the railways In 1909 and 1910 there were frequent strikes in the mining areas The boilermakers and the cotton operatives were involved in disputes Broadly speaking, these disputes were unsuccessful, and rising prices swallowed up such wage increases as had been obtained But through disappointment with the results of parliamentary action, the banner of "direct action" was raised The propaganda of the Social Democratic Federation and the Independent Labour Party was for the time, at any rate, overwhelmed by the propaganda of Industrial Unionism and Syndicalism, and a little later of Guild Socialism The trade union, in the eyes of those under the influence of the new intellectual ferment, was not merely a means of defence and a method of collective bargaining, it was a weapon with which to destroy capitalism Militant Industrial Unionism, as preached by the Industrial Workers of the World (*q v*), found few adherents Syndicalism found no home in Britain except in South Wales At the same time, it is undoubtedly true that these gospels influenced the outlook of the trade union movement, stimulated the movement towards federation and amalgamation, and prepared the way for the doctrines of Guild Socialism

The active agitation of the theorists and the rapid growth in trade union membership in the years immediately prior to the war, brought the general labour problem into greater prominence than ever it had enjoyed. The World War broke out and Trade Unionism was faced with new problems

The War and After.—From the period immediately prior to the outbreak of the World War down to the present time, the chief features of British trade unionism have been —

(1) The improved organization of and extension of trade unionism amongst "general workers" and women, in agriculture and on the railways, and in the public services and professions,

(2) The increasing importance of the trade unions in the community, and in the administration of legislation,

(3) The consolidation of trade union forces through the processes of amalgamation and federation;

(4). The growing authority of the executive body of the Trades Union congress

(5). The "General Strike" and the Trade Union and Trade Dispute Act 1927

Growth of Membership.—Trade union membership increased before and during the World War, especially among women, the curve rising rapidly during its later years, and culminating in the peak period of 1920, after which it progressively declined during the years of depression, recovering a little during 1924, but falling away again especially after the "general strike" in 1926

The highest degree of organisation amongst women is to be found in the cotton industry, where about 62% of the women workers are in the unions In the bleaching and dyeing trades, which are closely associated with the cotton industry, 50% of the women are organised; in the boot and shoe trade 48%; in printing, paper and bookbinding 36%; in the wool textile trades 32%; in linen and jute 28½ per cent Amongst shop assistants and clerks, and in the food, drink and tobacco trades, on the other hand, which employ in all over 750,000 women workers, the degree of organisation is very small Only 8% of the women shop assistants and clerks are members of unions and 2% of the female employees in the food, drink and tobacco trades.

Before the war the battle for the recognition of trade unionism was really won and the principles of trade unionism, which had been laid down primarily by the craft unions, were applied on the one hand by the larger body of semi-skilled and unskilled workers, and on the other hand by the "black-coated proletariat"—the salaried employees and professional people, such as public servants, draughtsmen, actors, salesmen, teachers and journalists

After 1914 new organisations arose and others which existed precariously before the war were put upon a firm foundation. Some of the new bodies, such as the Bank Officers' Guild, have not as yet affiliated with the Trades Union Congress, but they nevertheless exist for avowed trade union objects The National Federation of Professional, Technical, Administrative and Supervisory Workers was established in order to bring together the various organizations of non-manual workers.

Trade Union Membership

(All trade unions, registered and unregistered, in Great Britain and Northern Ireland)

The following table shows the total number of unions known to have been in existence in Great Britain and Northern Ireland in each year from 1913 to 1926, and their aggregate membership to the nearest thousand. (The figures of membership include members in overseas branches and in Irish Free State branches of such unions, but wholly exclude unions having their head offices in the Irish Free State).

Year	Number of trade unions at end of year	Membership at end of year			Percentage increase (+) or decrease (−) on total membership of previous year
		Males	Females	Total	
		Thousands	Thousands	Thousands	
1913	1,269	3,702	433	4,135	+21·0
1914	1,260	3,708	437	4,145	+ 0·3
1915	1,229	3,868	491	4,359	+ 5·2
1916	1,225	4,018	626	4,644	+ 6·5
1917	1,241	4,621	878	5,499	+18 4
1918	1,264	5,324	1,209	6,533	+18·8
1919	1,360	6,000	1,326	7,926	+21·3
1920	1,362	6,995	1,342	8,337	+ 5 2
1921	1,250	5,617	1,005	6,622	−20·6
1922	1,204	4,745	871	5,616	−15 2
1923	1,163	4,597	816	5,413	− 3 6
1924	1,159	4,721	813	5,534	+ 2·2
1925	1,144	4,666	831	5,497	− 0·7
1926	1,129	4,401	807	5,208	− 5·2

The steady growth in trade unionism immediately prior to the war may be attributed partly to a trade prosperity and partly to a recognition amongst all grades and types of workers of the need for effective organisation Certain legislation, such as the Trade Boards Act, 1909, and the National Insurance Act, 1911, strengthened the position of the trade union movement.

The increased membership during the World War was partly due to the influence of higher wages—which invariably result in enlarged trade union membership As the war went on high hopes were held out of a brighter future for the workers, the workers themselves, whose services, the community had realised, were essential to the prosecution of the war and to the satisfaction of the nation's needs, visualised more clearly their power in the State and saw in trade unionism a weapon to enable them to maintain in the time of peace the place their services had won for them in time of war But there were other factors operating Particularly in the munition trades, trade union membership became virtually compulsory. The Government itself, and a large number of employers actually encouraged workers in the larger industries to join a union Towards the end of the war the publication of the reports of the committee on employers and employed (better known as the Whitley committee) and their adoption by the Government, gave a new importance to the organisations of employers and workers, and in their desire to promote the establishment of joint industrial councils (and interim industrial reconstruction committees when the joint industrial council was not possible), members of the Government emphasised the value of effective organization (*see* INDUSTRIAL RELATIONS)

As a consequence of these various influences, between the early days of the war and the year 1920, the membership of trade unions doubled, reaching the figure of 8,337,000, of whom 6,995,000 were men and 1,342,000 were women During this time the number of women trade unionists was actually trebled Similarly, there had been phenomenal increases in the membership of unions catering for the less skilled workers. Before the war, what are known as the general labour unions had already become factors of some importance in the trade union movement. During the war period, their strength increased rapidly. The number of organised non-manual employees also rose much above the pre-war level.

Trade Union Membership (All Unions) Great Britain and Northern Ireland

Group of unions	No. of trade unions at end of 1926	Membership at end of 1926[1] Males	1926[1] Females	1926[1] Total	1925 Males	1925 Females	1925 Total	Percentage increase (+) or decrease (−) in membership at end of 1926 compared with end of 1925: Males	Females	Total

[1] The 1926 figures are subject to slight revision. Some unions cannot give separately exact numbers of male and female members. Estimates have, therefore, been given.

[2] The figures are exclusive of the membership of the general labour unions for which *see* GENERAL LABOUR.

[3] The total membership shown for all trade unions includes members in the Irish Free State and other overseas branches numbering approximately 58,000 in 1926, of whom 30,000 were engineers and other metal workers, and 16,000 were railwaymen and other transport workers. In compiling the figures for teachers, while certain associations, the majority of whose members are also members of the National Union of Teachers, have been omitted, others, which have also some members in this union, have been included, but the extent of this duplication is not ascertainable precisely. When allowance is made for all these factors, the *net* number of trade union members in Great Britain and Northern Ireland is estimated to have been nearly 5,140,000 at the end of 1926, compared with about 5,425,000 at the end of 1925.

[4] Leather, chemicals, rubber, brushes, musical instruments, etc.

[5] The figures for these two groups are affected by an amalgamation, a union with over 20,000 members which was grouped under general labour in 1925, having become merged in a transport union in 1926.

[6] The figures exclude teachers', tramway workers' and general labour unions for which *see* TEACHING, TRANSPORT and GENERAL LABOUR.

[7] Including unions of clerks, chemists, foremen, etc., when not classifiable by industry.

But just as rising wages are closely followed by a rise in the curve of trade union membership, so unemployment and falling wages are accompanied by a decline in it. The onset of the grave trade depression after the temporary post-war boom led to a decline of trade union membership amounting to 20·6% in the first 12 months, and a further 15·2% in 1922, the total roll of trade unionists falling in two years from 8,337,000 to 5,616,000. The net loss on the previous year's figure was less than 4%, whilst during 1924 there was a net increase

The backwash of the trade depression, and the disillusionment which followed the shattered dreams of post-war "reconstruction" had spent themselves. The trade union movement had shed the temporary passengers, and those who entered its ranks through the abnormal influences of the war and early post-war periods, and a definite attempt to stem the tide and re-create a powerful trade union movement had begun to take effect. The established minimum trade union membership may be taken as being about 5½ millions, an increase of over a million on the figures of 1913

From 1924 onward the general council of the Trades Union congress has pursued a policy of propaganda, first by means of a national "back to the unions" campaign and then by special activities with a view to the spread of trade unionism amongst women and agricultural workers respectively, whilst individual unions, though impoverished as the result of the long depression, renewed their efforts to secure an increasing membership But the efforts which were made to increase trade union membership met with a rebuff as a consequence of the National Strike of 1926, which led to a shrinkage of membership Since then, however, organising activities have been resumed with the result that members are being recovered. After 1926, the trade unions were far more concerned with rehabilitating their membership and finances than with the formulation of new demands. Indeed, their negotiations were primarily directed towards defending existing standards. The weak negotiating position of the unions was

Trade Disputes

[1] The 1926 figures are subject to slight revision. Some unions cannot give separately exact numbers of male and female members. Estimates have, therefore, been given.

[2] The figures are exclusive of the membership of the general labour unions for which see "General Labour."

[3] The total membership shown for all trade unions includes members in the Irish Free State and other overseas branches numbering approximately 58,000 in 1926, of whom 30,000 were engineers and other metal workers, and 16,000 were railwaymen and other transport workers. In compiling the figures for teachers, while certain associations, the majority of whose members are also members of the National Union of Teachers, have been omitted, others, which have also some members in this union, have been included, but the extent of this duplication is not ascertainable precisely. When allowance is made for all these factors, the *net* number of trade union members in Great Britain and Northern Ireland is estimated to have been nearly 5,140,000 at the end of 1926, compared with about 5,425,000 at the end of 1925.

[4] Leather, chemicals, rubber, brushes, musical instruments, etc.

[5] The figures for these two groups are affected by an amalgamation, a union with over 20,000 members which was grouped under general labour in 1925, having become merged in a transport union in 1926.

[6] The figures exclude teachers', tramway workers', and general labour unions for which see "Teaching," "Transport" and "General Labour."

[7] Including unions of clerks, chemists, foremen, etc. when not classifiable by industry.

[8] Comprising pottery and glass, food, drink and tobacco, and other manufacturing industries shown in table on p. 377.

[9] Comprising the entertainments and miscellaneous groups shown in table on p. 377.

one of the reasons for the lull in industrial stoppages after the settlement of the miners' dispute in 1926, whilst it was a contributing factor in the acceptance of the idea of the "Mond-Turner" discussions. The ebb and flow of direct action since the war is reflected in the table above (p. 378).

The broad distribution of trade union membership amongst the various industries is shown in the table on page 381.

The post-war period has been one of mixed gains and losses The unions in many industries secured the eight hour day, and apart from the increase of hours in the mines in 1926, the reduction in working hours is the most solid achievement standing to the credit of the trade union movement In some industries the unions have succeeded in maintaining real wages, in others they have had to make concessions. A feature of the disputes since the war has been what many people regard as their political character. It is certainly true that there has been more Government intervention and even participation in disputes than ever before The coal problem, which has dominated the post-war industrial situation was the direct cause of the so-called "general strike"

In July 1925, the T.U.C. general council promised its full support to the Miners' Federation even to the extent of a sympathetic strike. This step, however, was averted only to be implemented in the following year. The strike called by the T.U.C. general council, on the decision of a conference of trade union executives was the first occasion when the general council actually directed a stoppage, and it was the largest strike ever waged in British history The "general strike" and the defeat of the Miners' Federation was followed by the Trade Disputes and Trade Unions Act of 1927

The Trade Disputes and Trade Unions Act.—The history of Trade Union legislation prior to 1927 had been a history of liberation for the trade unions Adverse decisions of the law courts were rectified by Parliament The Act of 1927 definitely restricts trade union rights.

The principal changes which it makes in the law may be summarised as follows —

(1) Sympathetic strike action (whether on a national or local scale) if designed or calculated to coerce the Government, either directly or by inflicting hardship upon the community, is illegal, provided it is not within the trade or industry in which the original dispute arose (Section 1 [1])

(2). Lockouts are also similarly illegal.

(3). All primary strikes not connected with disputes over hours, wages or other conditions of employment are illegal, if they are designed or calculated to coerce the Government either directly or by inflicting hardship upon the community, *e.g*, a national coal strike to secure a statutory minimum wage. (Section 1 [1].)

(4). Any strike declared to be illegal by the Act will be none the less illegal, even though the workmen may have lawfully terminated their contracts of employment by due notice (Section 1 [1])

(5). A criminal liability is imposed on all union officials, which would include branch officials, shop stewards, members of strike committees, whether national, district or branch, and all other persons (excepting the workmen themselves) who in any way take part in or act in furtherance of any strike which is made illegal by the Act, even though they may be unaware of the facts or circumstances which render the strike illegal. Moreover, the individual workman who, in addition to ceasing work, acts as a strike picket or in any other way renders active support will be criminally liable. (Section 1 [2])

(6). In the case of strikes made illegal by the Act, the liability of union funds in respect of damages which may be awarded to employers and others, as imposed in the Taff Vale case, is restored. (Section 1 [4].)

(7). In the case of strikes made illegal by the Act, members expelled by their trade unions for breach of rule, *e g.*, members who remain at work after a strike has been called in accordance with the rules of the union, are given the right to claim damages, which will be payable out of the union fund. This right is made retrospective so as to cover the 1926 general strike. (Section 2)

(8). The statutory rights of trade unions to use their funds for political purposes are taken away, and the Act gives trade unions little in return which they do not possess under the present law, namely, the right which any group of individuals enjoys voluntarily to subscribe to a common fund. The 1927 Act, therefore, takes away the substantive legal rights conferred on trade unions by the 1913 Act, and, accordingly, is more than a mere change of machinery from "contracting-out" to "contracting in." (Section 4)

(9). Civil servants are prohibited from joining any trade union which is not confined to employees of the Crown, or which has political objects, or which is affiliated to any outside industrial or political organisations, *e g.*, the Trades Union Congress or the Labour Party. Any civil servant who fails to observe the above provision is liable to be dismissed from his employment, together with the loss of his pension (Section 5)

(10). Liability of municipal employees, or employees of any public authority, *e.g*, Port of London Authority, for breaches of their contracts of employment, to be a criminal as well as a civil liability, and so renders them liable to criminal prosecution, as well as the civil liability to pay damages (Section 6)

(11) The attorney general is given the right to interfere in union affairs by means of an application to the court to restrain the expenditure of union funds in support of strike action, declared illegal under Section 1 of this Act In this connection, it should be noted that under the present law, costs cannot always be obtained against the Crown, even when it loses the action. (Section 7)

Trade Unions and the Community.—The growth of trade unionism has meant that the trade unions have become an integral part of British social machinery This development has taken two main lines. In the first place, the trade union is now regarded as the normal machinery for the prevention and settlement of disputes. The State itself regards trade unions as responsible representative bodies They are called into consultation by the Government in times of dispute, and their leaders are invariably the spokesmen and advocates of the workers before courts of enquiry set up under the Industrial Courts Act. They express the workers' point of view before royal commissions and Government Committees, and the labour members of such investigating bodies are drawn from the ranks of organised labour On the Whitley councils in the Government services, the staff side is conducted by the representatives of the civil service unions The joint industrial councils concerned with services in which local authorities are interested are, like all other such councils, composed on the workers' side of trade unionists. The trade unions have won for themselves a definite place in the system of "industrial government," and they are parties to the industrial agreements which govern the relations between employers and employed, lay down the methods of consultation and negotiation, and determine wages and working conditions.

Share in State Administration.—In the second place, the trade unions play an important part in the administration of certain legislation. When the Trade Boards Act, 1909, was passed it was applied to four trades in which trade unionism was weak, and at the outset the interests of the workers were in large measure in the hands of the National Anti-Sweating League and the Women's Trade Union League. But trade unions have since been extended to almost every industry The Trade Boards Act of 1918, which amended and broadened the original Act, extended the minimum wage to trades to which hitherto the Act of 1909 had not been applied (*See* TRADE BOARDS.)

The Corn Production Act, 1917, set up agricultural wages boards on which the representatives of the unions catering for agricultural workers sat. The boards were, under the law, engaged in establishing binding rates of wages. The unions obtained a new status, and the Corn Production Act gave a new impetus to the difficult task of organising these workers When the act was repealed in 1921 the trade unions had nearly 300,000 members employed in agriculture. In 1924 the Labour Government re-established the system of wages boards, and the unions concerned are represented on the boards

The National Insurance Act of 1911 opened the door to trade union participation in its administration. Part I. of the act dealt with health insurance and provided, in general, for the payment of State benefit under the scheme by approved societies. Many trade unions formed trade union approved societies to administer the health insurance scheme, and these have become important agencies in the conduct of this vast system of social insurance A National Association of Trade Union Approved Societies exists to protect the interests of the constituent societies, and it played a prominent part in the opposition to Part I. of the Economy Act of 1926, which reduced the State contribution to health insurance. The insurance activities of the unions have not only associated them with the working of an important piece of legislation, but have consolidated, and in some cases strengthened, the position of the unions with their own members.

Part II of the National Insurance Act, 1911, dealt with unemployment insurance, but the scheme was a limited one. Compulsory insurance against unemployment was widely extended by the Unemployment Act of 1920 to cover nearly 12,000,000 workers. Provision was made whereby trade unions which ordinarily distributed out-of-work pay to their members should, subject to certain conditions, be allowed to administer the State Scheme, and pay the State benefit to their members, for which service the unions received an allowance. Many unions applied this provision of the act, but the reduction of the administration allowance from 1s per week benefit paid to sixpence led to some unions ceasing to administer the act. At the end of 1928, however, unions with a membership of 962,370 were still operating under Section 17 of the Act of 1920. and in order to secure a common policy on matters affecting their position under the Unemployment Insurance Acts, the unions concerned set up a standing committee, which acts with the Trades Union congress general council.

On the local employment committees and juvenile advisory committees attached to the employment exchanges and on the juvenile choice of employment committees of local authorities, the trade unions are represented, whilst when "uncovenanted" or "extended" benefit was introduced, they were actively associated with the employment exchange rota committees for the administration of this form of benefit.

During the progress of the war the trade unions were intimately connected with the conduct of certain phases of national affairs. In March, 1915, the Government came to an agreement (known as the Treasury agreement) regarding the production of munitions, which included compulsory arbitration, the relaxation where necessary of trade union rules, and the limitation of profits in munitions industries. From then onwards, the unions were called upon to assist in accelerating the production of munitions, in administering certain of the controls which were instituted (such as those in the cotton and wool textile industries) and in the selection of men for war service. Parts of the Treasury Agreement were embodied in the Munitions Acts, and offences under these Acts, except such as were brought before the ordinary courts, were dealt with by specially appointed munitions tribunals. Each tribunal consisted of a chairman, with either two or four assessors, drawn equally from panels representing employers and workers respectively. These bodies played a great part in the administration of the Munitions of War Acts.

A "national labour advisory committee on war output" was established early in the war, together with local labour advisory boards in each munitions area. The national committee was replaced in 1917 by the Ministry of Munitions trade union advisory committee, which was divided into three sections representing the engineering group, the shipbuilding group and the general labour group. A special women's trade union advisory committee was also appointed in the same year to advise the minister on all questions relating to women's work. Towards the end of the war further steps were taken arising out of unofficial strikes in Coventry and Birmingham, which, though speedily settled by the trade unions concerned, led to the appointment of a Government committee (on which there was trade union representation). This committee, which was critical of the policy of the Ministry of Munitions, recommended the establishment of a joint committee of employers and trade unionists and the closest possible consultation, both nationally and locally, upon changes and developments of policy—a proposal which the Government accepted.

The recruiting of men for the army was in the early stages of the war left entirely to the War Office. But haphazard recruitment led to the crippling of essential industries by the withdrawal of skilled men in considerable numbers, and to industrial unrest. It was therefore found advisable to bring trade unions into consultation on questions of recruiting.

Similarly, when the Government imposed its control over certain industries, the trade unions primarily concerned played an active part. The cotton and wool textile controls may be taken as an illustration. The cotton control board (set up in 1917) determined the amount of machinery which was to be run upon other than Government orders, and imposed a levy upon concerns working full time to pay out of work benefit to workers employed by firms suffering from the operation of the raw cotton order (which prohibited the purchase of cotton except under licence) and the control board. The wool control board, also instituted in 1917, consisted of eleven representatives of the trade unions, the employers and the War Office contracts department.

After the World War, these various forms of organisation came to an end, but they had given a new standing to the trade union movement. Since 1918 the chief administrative activities of the trade unions have been in connection with health insurance, unemployment insurance and trade boards.

The Consolidation of Trade Unions.—The movement towards consolidation of trade union forces which has been a marked feature in recent years was partly the outcome of the theoretical teaching of Syndicalism and Guild Socialism, but it was largely due to experience and the hard facts of economic life.

Federations have changed from loose alliances to negotiating bodies acting on behalf of the constituent unions. This development is seen in the case of the Engineering and Shipbuilding Trades Federation and the Miners' Federation of Great Britain, though the latter under the Coal Agreement of 1926 is no longer a negotiating body. In Nov. 1910, on the initiative of the Dockers' Union, the National Transport Workers' Federation was formed comprising practically all the unions catering for workers employed in waterside transport, including seamen, dockers and carters. This Federation, however, has since gone out of existence.

The Triple Alliance.—The Triple Industrial Alliance which was formed in 1914 was, in effect, a federation consisting of the Miners' Federation of Great Britain, the Transport Workers' Federation and the National Union of Railwaymen; it was thus composed of two bodies which themselves were federations and one large industrial union. The associated bodies were the unions concerned in the key industries of coal and transport, and the formation of the alliance created some consternation. But the only occasion when the Triple Alliance decided to embark upon industrial action was during the coal stoppage of 1921, when the Alliance issued notices calling a strike in support of the miners. The notices, however, were postponed and then withdrawn on April 14 (Black Friday). The result was to destroy the Alliance, but the association of railway, transport and mining unions continued, as they formed one of the "groups" constituted by the general council of the Trades Union congress. In 1925 attempts were made, largely on the initiative of the Miners' Federation, to establish a new alliance on a broader basis than the Triple Alliance; but, as membership of the new alliance involved in some cases an alteration of the rules of certain unions, and as the implications of the proposed association needed careful consideration, the completion of the alliance hung fire, and was abandoned.

Textile Trades.—In June, 1916, the National Association of Unions in the Textile Trade was established. Of the 36 unions of which the association is composed, 20 represent wool textile workers. The association, however, includes, besides workers engaged in manufacturing and finishing processes, those engaged in the textile machinery trade, and the skilled workers engaged in the maintenance of plant. The association appoints the workers' representatives on the joint industrial council of the wool textile industry. But the association also exists to promote trade union amalgamation in the industry, and to secure co-ordination in the case of disputes.

General Workers.—The General Labourers' National Council (established in 1908) developed in 1917 into the National Federation of General Workers, composed of the seven chief unions of general workers with an aggregate membership of over 800.000.

Building Trades.—The National Building Trades Council (representative of the 13 chief unions in the building industry) formed the basis for the National Federation of Building Trades Operatives established in 1918.

Foundry Trades.—Early in 1918 the Federation of Foundry Trades came into existence to promote amalgamation of the Unions in the industry, deal with demarcation disputes, and secure joint action wherever possible. It included about a dozen unions with a total of between 50,000 and 60,000 members. Three of the

unions in the federation—the Friendly Society of Ironfounders, the Associated Ironmoulders of Scotland and the Amalgamated Society of Coremakers, in 1922 merged to form the National Union of Foundry Workers

The G.F.T.U.—The General Federation of Trade Unions has changed its character. It does not now take any active part in trade union disputes and negotiations or in the work of promoting closer industrial organisation The G F T.U. was formerly the medium of communication between the British and foreign trade union movements, but since 1920 the general council of the Trades Union congress has been the representative British organisation in the International Federation of Trade Unions The chief work of the G F T U is in connection with dispute pay. Contributing associations pay contributions to the federation on the basis of their membership, and receive, when involved in a stoppage of work, benefit to be paid to their members In 1925 there were 118 unions affiliated to the federation with a total membership of 830,316 members

The following table gives the number and gross membership of federations in Great Britain and Northern Ireland at the end of each year —

Year	No of federations	Approximate total membership
1913	125	4,370,000
1914	137	4,730,000
1919	134	9,896,000
1920	116	10,749,000
1921	105	8,623,000
1922	95	6,236,000
1923	92	5,580,000
1924	90	4,442,000
1925	83	4,203,000
1926	84	3,909,000

The number of federations has shown a decline at the end of every year since 1917, except 1926, when there was an increase of one In some years the decline was mainly due to the merging of local into national organisations

In many instances trade unions, or branches of trade unions, are affiliated to more than one federation, and therefore a large number of trade union members are counted more than once in the gross membership given above In the following table the actual or estimated federated membership of each federated trade union is counted once only, irrespective of the number of federations to which the trade union is affiliated, and the table shows for the years 1925 and 1926 (*a*) the total membership (to the nearest thousand) of the trade unions in each group, (*b*) the net federated membership (whether of trade unions or of sections of branches of trade unions), and (*c*) the percentage proportion of (*b*) to (*a*).

Group of trade unions	Total membership of trade unions (000's omitted)		Net federated membership of trade unions affiliated to federations (000's omitted)		Percentage proportion of federated membership to total membership	
	1925	1926	1925	1926	1925	1926
Agriculture, horticulture, etc	47	39				
Mining and quarrying	914	787	891	749	98	95
Metals, machines, conveyances, etc.	683	658	333	305	49	46

Commerce, finance, etc	222	217	98	97	44	45
National and local government	333	332	101	104	30	31
Teaching	197	200		.		
Miscellaneous	165	161	59	56	36	35
General labour	488	474	111	89	23	19
Totals	5,497	5,208	2,889	2,624	53	50

Amalgamations.—Federation has in many cases proved to be a stepping stone to amalgamation; but in other cases unions have merged without the intermediate step of federation. The reduction which is taking place in the number of trade unions is in part due to amalgamations as may be seen from the following table:—

Year	New unions formed (other than by amalgamations)	Reductions due to		Net reduction (−)
		Dissolutions	Amalgamations	
1921	45	72	85	−112
1922	30	40	36	− 46
1923	17	41	17	− 41
1924	27	17	14	− 4
1925	20	31	7	− 18
1926	27	30	12	− 15

One of the most striking amalgamations which was carried through prior to the Act of 1917 was that which resulted in the establishment of the National Union of Railwaymen. Up to 1913, when it was formed by the merging of three independent unions, the railway unions had not yet won full recognition from the companies. The N U R. shares with the Associated Society of Locomotive Engineers and Firemen, which is a craft union, and the Railway Clerks' Association, the representation of railway employees, and with certain other unions, the representation of the workers in the railway engineering workshops The N.U R. illustrates both the tendency towards larger scale organisation, for its object is "to secure the complete organisation of all workers employed on or in connection with any railway in the United Kingdom", and also the incomplete success it has achieved and the difficulties inherent in this policy. In time, the Associated Society of Locomotive Engineers and Firemen and the Railway Clerks Association may possibly merge into the National Union of Railwaymen; but the organisation of the engineers, boilermakers. carpenters and other railway shopmen, for which other unions cater, is a problem raising a conflict of principle

A new method of consolidation was adopted in the establishment of the British Iron and Steel and Kindred Trades Association and the Iron and Steel Trades Confederation in 1917 The former was, in effect, a new union which the various participating unions influenced their members to join These unions admitted no further members, all new members joining the B I S A K T A., and they transferred their powers to the Iron and Steel Trades Confederation, which conducts the work of organisation and negotiation When all the members of the participating unions have been transferred to the B I S A K.T A it will assume the duties and powers of the Confederation, which will then cease to exist.

The Amalgamated Engineering Union, one of the largest post-war amalgamations, illustrates the consolidation of craft unions. The nucleus of the present union was the Amalgamated Society of Engineers, with which nine other craft unions engaged in engineering coalesced in 1920 The A E U. catered for skilled mechanics, but has now opened its ranks to other grades of workers

January, 1921, saw the establishment of the Amalgamated Society of Woodworkers, the nucleus of the new organisation being the Amalgamated Society of Carpenters and Joiners In the same year, the Amalgamated Union of Co-operative and Commercial Employees and the National Warehouse and General Workers' Union merged to form the National Union of Distributive and Allied Workers The Amalgamated Union of Building Trade Workers formed at the beginning of 1921 was an amalgamation of the Operative Bricklayers' Society, the Manchester Unity of Operative Bricklayers, and the Operative Society of Masons, Quarrymen and Allied Trades. In 1922, the Dock, Wharf, Riverside and General Workers' Union formed the

nucleus of an amalgamation under the name of the Transport and General Workers' Union, uniting the National Union of Dock Labourers, the National Union of Vehicle Workers, the United Vehicle Workers (which was an amalgamation of the Tramway Workers and the Licensed Vehicle Workers) and several other unions. The Gasworkers' and General Labourers' Union, as it was originally called, became the National Union of General and Municipal Workers, when in July 1924 it absorbed the National Amalgamated Union of Labour and the Municipal Employees' Association In 1923, the National Federation of Women Workers was merged in the National Union of General and Municipal Workers Discussions have since taken place with other unions, *e.g*, the Workers' Union and the Transport and General Workers' Union as to the possibility of further amalgamation. A ballot is taking place of the T. & G W. Union and the Workers' Union members on the question of amalgamation of these bodies Other post-war amalgamations include the United Garment Workers (1920) which unified several sectional and local bodies, the Union of Post Office Workers formed (1920) by the combination of three unions, and subsequently enlarged by the absorption of half a dozen other organisations of post office employees, the National Union of Blastfurnacemen (1922) which took the place of the National Federation composed of five local unions of blast furnace workers, and the National Union of Sheet Metal Workers (1921) which combined a number of small federated societies of steel metal workers and braziers

The spontaneous movement towards amalgamation which characterised the first post-war years appears to have come to an end about 1922–3 It was at this time that the matter was taken up by the Trades Union congress Since then, its general council has played an active part in assisting negotiations for amalgamation. It has held conferences of kindred organisations in the metal trades, the textile trades (other than cotton), the printing trades, the post office, the insurance industry, the dyeing, bleaching and finishing trades, the leather trades, the building trades and amongst distributive and clerical workers In some cases the conferences broke down after a time, in others they have continued; but the process is slow and tedious and many practical difficulties have to be overcome The Swansea Trades Union congress (1928) showed quite clearly, however, that the practical difficulties must not be allowed to stand in the way of greater consolidation

General Policy.—During the years preceding the World War there was considerable labour unrest due largely to the steadily rising cost of living but receiving inspiration in some degree from the intellectual ferment in the world of labour Syndicalism, though never a potent force in the British trade union movement, prompted and encouraged the movement towards militant industrial unionism. The persistent propaganda of the Socialist societies had also begun to influence the outlook of the trade unionist. From about 1910 it is clear that the trade union movement, as may be seen from the resolutions of the T.U.C. was Socialist in temper. It was definitely in opposition to capitalism and private ownership of the means of production. The socialism, however, to which trade unionism gave adhesion, was essentially collectivist; but a closer association with the problems of industry, and a widening knowledge of the world of industry led to a sense of dissatisfaction with the arid doctrines of undiluted collectivism, which came indeed to be described as "State capitalism" Syndicalism, whilst it never commanded a large measure of support, did, by its emphasis on the workers' right to control, indicate the possibilities of a policy which whilst providing for public ownership, escaped the charge of "State capitalism" by the adoption of the principle of democratic control.

During the pre-war years these ideas had not clearly emerged. The effects of State regulation during the war, however, powerfully assisted in swinging active trade union opinion round to a sympathetic appreciation of the essential doctrines of Guild Socialism. Moreover, the new importance of the labour element in the community gave birth to new aspirations, and to the claim that the workers should enjoy increasing responsibility and power in the actual conduct of industry One of the most powerful groups of influences which moulded the minds of organised labour were those connected with the conditions of war-time employment. In the chief industries, the unions were parties to arrangements for the increase of output and the avoidance of stoppages of work.

Shop committees sprang up in the munitions industries, and in the engineering trades particularly they became influential organisations. Shop stewards became the real leaders of the rank and file in matters affecting the day to day lives of the workers in industry. This new reorganisation within the industrial labour movement—the creation of the circumstances in which the trade union executives were inevitably placed—proceeded swiftly and to a considerable extent effectively. It was unknown to the general public until it had established itself It was spontaneous —an obvious method of satisfying the need for some rapid local machinery which could deal with grievances in the workshop.

It spent itself during the war. With the end of the war, it lost the passion which had sustained it; but the value of shop committees and shop stewards (*q v*) was recognised, first in the engineering industry, and subsequently in others, the unions adopted this machinery and grafted it on to their organisations.

In the meantime, the policy of self-government in industry had become crystallized, and since the war, the T U.C. has accepted the policy of public ownership combined with the association of workers in the government and control of industry The application of this policy may be seen in the bill prepared by the Railway Clerks' Association for the nationalisation of railways, and subsequently in the scheme for the future of the coal industry placed before the coal commission of 1925–26 by the Miners' Federation, with the full support of the T.U C general council and the Labour Party In the discussions at the Swansea T U.C (1928) on the "Mond-Turner" conferences, it was strongly urged by the secretary of the congress that it offered an avenue to "industrial control," and to the participation of organised labour in the direction of industrial policy

Russia and Communism.—The Bolshevik revolution in Russia had its reaction upon the British trade union movement Some of the leaders of the shop stewards' movement embraced Communist doctrines, and when the Red International of Labour Unions was formed by the Moscow Communist International, attempts were made to secure the adhesion of trade union bodies to the R.I L U. Such British bodies as are affiliated, however, are not national unions, but sectional and local organisations. Under the inspiration of communist doctrines the "National Minority Movement" was organised, as what may be called the communist wing of the trade union movement. It consists of groups and sections of trade unions, and its spokesmen favour an advanced policy supporting also closer relationship between Britain and Russia The general council of the congress has actively supported a policy of friendship between Britain and Russia and has used every effort to bring about an understanding between the International Federation of Trade Unions and the Russian trade unions Its efforts met with no success and even the attempt to reach an understanding between Russian and British trade unionism failed, and in 1927 relations between the two were virtually broken off

The National Unemployment Workers' Committee Movement established during the period of heavy post-war unemployment, is, like the minority movement, directed largely by people of communist sympathies. From 1923 the T.U.C. co-operated with the N.U.W C M., but in 1928 the general council decided that "no useful purpose would be served by the continuance of the joint committee with the N.U W C M.," and declared that it was not satisfied "as to the *bona fides* of the organisation." The congress of 1928 accepted this statement, and moreover, adopted a resolution instructing the general council to institute "an inquiry into the proceedings and disruptive elements within the trade union movement . . . and to submit a report with recommendations to the affiliated organisations." The debate on this motion made it clear that the resolution was directed against the National Minority Movement and the Communist Party.

The militant left wing was in the ascendant during the earlier years of the trade depression. It reached its maximum influ-

ence at the Trades Union congress in 1925. The National Strike and the prolonged coal stoppage in the following year, whilst creating a despair which provided a fertile soil for Communist propaganda particularly in the mining areas, ultimately resulted in a definite swing to the right. On the coalfields a "non-political" form of trade unionism secured a precarious foothold. In other unions Communist influence waned after the events of 1926 and some trade union organisations excluded Communists and members of the National Minority Movement from representative positions. The Trades Union congress of 1927 indicated a clear change of attitude and the trade unions at their congress in 1928 repudiated the policy and tactics of the left wing, condemned its disruptionist activities, and declared by an overwhelming majority in favour of the continuance of the "Mond-Turner" consultations, a series of conversations between the general council and a group of prominent employers, with the object of securing as far as possible peace in industry.

The factors which have led a minority of trade unionists into the ranks of Communism and the National Minority Movement (which it may be said includes a considerable proportion of workers who could not be described as Communists) have led a far greater number to a realisation of the need for a clearly conceived industrial policy for the trade union movement The establishment of the general council of the Trades Union congress, the enlargement of its powers, and the large extension of its activities were an expression of this need. One of the first problems, however, is that of the organisation of trade unionism; for clearly the success of any industrial policy must depend in the last resort on the efficiency of trade union organisation.

Trade Union Organisation and Policy.—So long ago as 1910 and 1911 the Congress committed itself to the principle of organisation by industry, and in 1911 urged the parliamentary committee to call conferences of the different industries "with a view of amalgamating the several trade unions connected with each industry." This somewhat crude principle was interpreted in a reasoned resolution adopted by the congress in 1918, when it was agreed (*a*) that the organisation of an industrial union should allow for the maintenance within the union of each distinct craft combination and for the possibility of federating such combinations with like bodies outside the union for specific purposes; and (*b*) that every craft union and general labour union should allow sectional combinations within the union, on industrial or occupational lines, so as to facilitate inter-union federations, and, if circumstances require, the transfer of a section to any more appropriate union.

In 1922 the Trades Union congress instructed the general council to make an enquiry into the present organisation of the trade union movement as a necessary basis for a policy of closer unification. The Hull congress of 1924 adopted a resolution declaring that "the time has arrived when the number of trade unions should be reduced to an absolute minimum" and that "the aim should be as far as possible organisation by industry with every worker a member of the appropriate organisation." The congress called upon the general council to prepare a scheme, and a committee was appointed A memorandum by W. M Citrine on the subject was published in the annual report of the congress for 1925. The report which was submitted to the T U C. in 1927 boldly admits the defects of the existing trade union structure and method—the prevailing sectionalism, the competition between different unions for workers, varied rates of contributions and benefits, demarcation of work and the lack of a co-ordinated policy. The council, which has taken an active part in promoting conferences of unions with the object of assisting amalgamation, realises that "the real driving force must come from the unions themselves." It sees no value in laying down a hard and fast scheme, but believes that joint working arrangements should be made wherever possible. After the congress of 1927, the general council circularised the affiliated unions on their attitude towards amalgamation and joint working In most cases the unions were in favour of the latter, many were in favour of the former, whilst some were impressed by the difficulties and past failures as regards amalgamation. The Swansea Trades Union congress of 1928 adopted by a large majority a resolution calling upon the general council "to appoint a reorganisation commission to review the situation of the workers in the principal industries in the light of the material which it has at its disposal, and to formulate suggestions for the speedy reorganisation of the trade union movement." It is certain that the conflicting claims of pure and unadulterated industrial unionism, occupational unionism, federal unionism, and craft unionism, will necessitate some composite method which, within the framework of the industry, permits variety of organisation to meet the needs of special crafts and groups, but, at the same time, one which is comprehensive enough to cover as wide a ground as the modern organisations of capital

THE UNITED STATES

Something more than 3,500,000 American wage-earners were in 1928 members of labour organizations This membership is scattered over all fields of employment—the manufacturing industries, land and water transportation, the building trades, the mining industry, the professions, domestic and personal service and trade. Organized labour is not everywhere equally strong. In the building trades organization is general and dominant. On the railroads it is powerful largely among the skilled train-service employees. In the coal industry the strength of the union, the United Mine Workers, is on the wane, except in the anthracite industry Among the many manufacturing industries of the country, trade unionism can be regarded as strong only in the clothing and printing industries. For the rest union members are to be found in a large variety of occupations such as actors, barbers, street railway employees, teamsters and chauffeurs and in a few branches of public service. The American labour movement is, moreover, a men's movement.

Knights of Labor.—As a continuous, more or less unified movement, with its peculiar philosophy and strategy, trade unionism in the United States cannot be said to have become established before 1880 In the preceding decades several of the large national unions had been organized and occasionally more general uprisings had taken place only to die out after a few years, usually in the wake of business depression By 1880, the Knights of Labor, organized in 1869 and pursuing since then a secret existence, had appeared in the open as a union of all workers, skilled and unskilled, manual, clerical and professional, and even of the small business man During the next ten years there was unfolded one of the most dramatic and significant episodes in the history of American labour. Hardly known at the beginning of the period the Knights achieved by 1886 a membership of close to 1,000,000 and an influence far transcending its size

The Knights had set out first to organize all workers. For this slow and gigantic task, the organization had neither the financial resources nor an adequate staff of organizers It depended on the spontaneous uprisings of men and women Such uprisings occurred often in the few years from 1880 to 1886 But when strikes ended in failure and strikers lost their jobs and when there

was no place to turn for the sinews of war, it became more difficult to arouse enthusiasm and action At the same time much of the attention and energy of the officers of the organization was dissipated in carrying out the ambitious economic programme of the Knights, which ran from simple trade union action over wages to vast co-operative schemes or plans for the reorganization of the currency and banking system of the country. To these sources of weakness, was added the inevitable conflict for jurisdiction between the Knights and the established craft unions The episode of the Haymarket bomb in 1886 brought the Knights of Labor into disrepute but only hastened the end.

Rise of the American Federation of Labor.—Even during the heyday of the Knights, a new central organization of American labour was already forming under the leadership of Samuel Gompers and his associates. This organization, appearing in 1886 as the American Federation of Labor, had as its precursor the Federation of Organized Trades and Labor Unions begun in 1881. The Knights sought to absorb the existing craft unions; to subject them to the loss of autonomy; and to involve them in industrial disputes, in which their own direct interests were apparently not at stake. Against this tendency craft unions revolted, organizing themselves in the loose federation which is still the sole centralizing and unifying agency of the American labour movement.

The principles on which the American Federation of Labor (*q.v.*) was founded originated in the practical experience of the leaders of this new movement and in their reaction against the practices of the times They saw in craft unionism the solidarity and permanence which they found missing in the industrial unions, mixtures of skilled and unskilled, sponsored by the Knights. They observed that the best chances of continuity and strength in a movement of organized labour lay in formulating narrow and attainable economic objectives instead of embracing a large and attractive programme of economic reform which the trade unionists themselves had neither the interest nor the capacity to make effective In view, finally, of the frequent and disastrous failures of independent political action, they abandoned attempts to form a Labour Party and sought to achieve political influence by other means. In its beginnings, then, the American Federation of Labor was dedicated to the principles of craft unionism and autonomy, of the collective bargaining that wins recognition of organized labour and advances in working conditions.

To this plan the Federation has consistently adhered. This undeviating policy has made of it a loose federation of nearly 150 national and international unions, each of which retains full autonomy over all of the affairs that are the concern of a modern labour organization In return each union receives from the Federation protection of its charter or of the workers and industrial territory over which it claims jurisdiction Out of this policy have grown bitter jurisdictional disputes between unions affiliated with the Federation Although the Federation has usually thrown the weight of decision and influence toward the claimant with the clearest title to the disputed jurisdiction, this has not prevented far-reaching changes in the structure of affiliated unions

Economic and Social Policy.—The American Federation of Labor has become the agency for dealing with all matters affecting the general welfare of organized labour The most absorbing of these matters are, of course, political. From the beginning the Federation has concerned itself with measures for ensuring the proper legal status of organized labour and has employed to this end whatever political influence it could muster Just as Samuel Gompers fought in 1890 for the exemption of organized labour from the terms of the Sherman Anti-Trust Act, so the present leaders of the Federation were in 1928 demanding of the major political parties protection against the use of injunctions in labour disputes and the promise of a liberal legal status Similarly throughout the States and municipalities of the country, federations of the local branches of the unions affiliated with the Federation pursue their activities as lobbyists in the interest of labour; agitate for raising wages on public works; mobilize their power for the repeal of unfriendly legislation, or for the defeat of an "anti-labour" candidate for local office

The American Federation of Labor, acting as spokesman for organized labour, frequently states the position of labour on questions of general economic and social policy. Until recently the Federation has been anti-monopolistic in its attitude toward combinations of business. From almost the very beginning the Federation has been "on record" for the restriction of immigration. It urged the recognition by the United States of the labour government of Mexico but has opposed the recognition of the Soviet government of Russia. Through resolutions adopted at its annual conventions or through manifestoes issued by its Executive Council, the Federation constantly expresses the views of organized labour on a great variety of questions.

Independent Unions.—Outside and independent of the American Federation of Labor are a group of national unions that now have a combined membership of about 800,000. This group consists mainly of the railroad brotherhoods, the unions of locomotive engineers, firemen, conductors and trainmen, of the Amalgamated Clothing Workers of America, and of smaller organizations largely in public service and in the textile and metal industries The railroad unions have at no time been affiliated with the Federation, preferring to preserve full control over their own internal affairs. The Amalgamated Clothing Workers started in 1915 out of a split in the United Garment Workers and is consequently known as a secessionist organization. Occasionally unions that have been independent, like the Bricklayers, join the Federation, or affiliated organizations, like the Railway Clerks, lose their charters and become independent But such changes have, in the history of the movement, been rare The Industrial Workers of the World ("I W W") is separately dealt with

Analysis of Growth.—As an effective force in American industry, organized labour hardly began to be felt before 1900 The period following the collapse of the Knights of Labor was one devoted to building the foundations of the labour movement, to strengthening the few established organizations and to extending unionism into new fields The decade 1890–1900 with its severe depression and general unemployment was not favourable to the growth of unions With the recovery of business toward the end of the decade the growth of the labour movement began and continued with only slight recessions until 1920 From 1900 to 1914, as the table shows, the total membership of American

Year	Membership	Year	Membership
1897	447,000	1913	2,753,400
1898	500,700	1914	2,716,900
1899	611,000	1915	2,607,700
1900	868,500	1916	2,808,000
1901	1,124,700	1917	3,104,600
1902	1,375,900	1918	3,508,400
1903	1,913,900	1919	4,169,100
1904	2,072,700	1920	5,110,800
1905	2,022,300	1921	4,815,000
1906	1,958,700	1922	4,059,400
1907	2,122,800	1923	3,747,200
1908	2,130,600	1924	3,746,600
1909	2,047,400	1925	3,817,900
1910	2,184,200	1926	3,900,500
1911	2,382,800	1927	3,903,800
1912	2,483,500		

trade unions increased by nearly 2,000,000 and trade unionism penetrated many unorganized industries, making its most notable advances in the coal industries. Among the manufacturing industries the progress of organization, while substantial, was slow.

This whole situation changed radically after the outbreak of the World War. The rapid improvement in business and rise in productive activity, the steady absorption of the unemployed in face of the cessation of immigration, the further stringency in the labour market after the American entry into the war, the rising levels of prices and of wages, were all factors contributing to the strength of organized labour The membership of trade unions, consequently, nearly doubled from 1915 to 1920 and unionism won a place for the first time in the textile industry, packing houses, in machine shops, among the shop men and unskilled on the railroads, in the clothing industries and among many clerical occupations. Only in the iron and steel industry did the labour

movement fail to make effective progress.

The war gains were not held. The concomitants of ordinary business depression, unemployment, strikes and lockouts and the shrinkage in the purely war industries had an immediate and devastating effect on trade unions By 1923 they had lost nearly 1,500,000 members and were eliminated from many of the industries which they had for the first time entered during the war Strikes on the railroads reduced the unions of the unskilled almost to nothing and left the shopmen in control of only a few roads. The machinists' union lost more than 230,000 members, and the United Mine Workers began that series of engagements with the mine operators which has seriously impaired the strength of this union throughout the bituminous coal industry Only in the clothing, building, transportation, printing, public service and theatrical groups is the trade union larger and stronger in 1927 than it was in 1913 Nearly 60% of all union members were in 1927 in the building, transportation and clothing unions At first blush the failure of trade unions generally to do better than hold their own in these past years is surprising For, since the revival of 1922, American business and industry has had an astounding record of high levels of production and large profits. Under such conditions in the past labour organization has usually grown. In the building trades the unions have clearly profited from the business boom Elsewhere this has not been the case

Handicaps to Growth.—For generations American industry drew a substantial part of its labour from the masses of immigrants that every year came from the countries of Europe into the United States Although there has been drastic restriction of immigration since the war, American industry appears to be still far from a condition of labour shortage There are new sources of labour within the country that are constantly being tapped and that conduce to an easy labour market

All labour movements suffer from the internal dissension that arises out of clash of doctrine Sooner or later the holding of a new view of the purposes of the labour movement grows into an attempt to capture the movement and to convert it to this view Mild beginnings in this direction have usually ended in bitter warfare and in the disruption of one or more unions. Such was the early history of the relations between the labour movement and the socialists, after 1905 between the I W W and the American Federation of Labor, and since the war between the communist movement and the established trade unions In the clothing industry, for instance, the struggle for control waged during the past few years between the communist Workers' Party and the administration of several of the unions in this industry has resulted in nearly destroying organizations that were only a few years back among the most effective in the country.

American unions have always had an uncertain legal status They have been constantly harassed and hindered by the free use of injunctions in labour disputes. Prohibitions against interference with interstate commerce have applied to trade unions as to business combinations The device of the individual or "yellow-dog" contract, by whose terms a worker holds his job as long as he agrees not to join a labour organization, has almost closed certain areas and industries to unionism. Throughout the 48 States of the country, labour unions encounter almost as many different legal conditions as there are separate judicial jurisdictions. Sustained efforts of the movement to clarify and improve its legal status have hardly been successful. It is clear that the great expense of litigation in the United States and the uncertainty of the outcome have been severe handicaps to the growth of labour organization.

In the face of a swiftly changing industry, whose technical processes are being constantly revolutionized, the unions have clung to an antiquated structure. New industries like the automobile industry and even old ones like the shoe and clothing industries have all participated in this metamorphosis. Old categories of skill have disappeared and new ones have not arisen in their place Over these machine tenders and semi-skilled workers the jurisdiction claims of the established labour unions are vague and ineffective. Where the job in hand demands pioneer activities and a bold strategy, the divided counsel of many separate unions has been a source of weakness.

Company Unions.—Organized labour in the United States, finally, has in recent years been forced to meet a new strategy of employers For the moment, at least, many industrial leaders appear to have abandoned the repressive measures of the past and to have engaged in competition with labour unions for the loyalty of their employees In place of the national trade unions, whose members are recruited throughout the whole of an industry, regardless of geographical location or ownership of the business, industry has created company or plant unions (*See* COMPANY UNIONS) These organizations, sometimes described as employee representation plans or works councils, are limited either to a single plant or to several plants under common ownership. Their number has grown so rapidly since the World War that their present membership may run to several millions

To this device many industries have added the so-called welfare features, which have already assumed a great variety of forms The most common are the sale of a company's securities to its workmen at prices and on terms that are generally more favourable than could be obtained in the open market and the wholesale purchase for all of its employees of insurance against death, and occasionally against sickness and old age Both practices have been growing by leaps and bounds and should, if they continue at the present rate, profoundly affect the distribution of income in the United States The leaders of organized labour are critical of this whole development, question the *bona fides* of the employers and point to crucial defects in both the systems of employee representation and in the new insurance and investment features of labour relations

Trade Union Problems.—The most fundamental of the trade union's problems is that of adjusting its policies to changing economic conditions Very often, before the World War as well as since, strong and established trade unions have been reduced in size and strength because they failed to gauge the probable inroads of machinery and business depression Sometimes the struggle between a union and machinery would last for a generation, but in the end the union was beaten This has been largely the history of the cigarmakers' union In general, also, nearly all of the organized industries in this country are partly non-union. Unless the union is able to organize the non-union area, or so to protect the competitive position of the union area that the non-union firms do not grow, the union will find business being diverted to the unorganized area and control of the industry slipping from its hands The failure of the United Mine Workers to organize the non-union coal fields of West Virginia and at the same time to strengthen the competitive position of the union operators in Illinois, Pennsylvania and elsewhere has more than any other single factor led to the disruption of their union

Advances in Economic Policy.—In the past years several trade unions have made notable advances in the direction of a new economic policy One of the best-known of these experiments is that begun in 1923 between the Machinists' Union and the Baltimore and Ohio Railroad Company (often called "B and O Plan"). The essence of the experiment is the assumption by the union of responsibility for production Under this plan officers and members of the union, working in the shops of the railroad company, undertake to contribute to efficiency In turn the company promises the union a share of the gains from increased output. This arrangement has unquestionably strengthened the union and may be expected to lead gradually to a general improvement in working conditions It has already spread to the Canadian National Railways and to other railroads in the United States. Probably the most significant and far-reaching development of this kind has taken place in the men's clothing industry under the initiative of the Amalgamated Clothing Workers, the union of men's clothing workers. This organization began only in 1915 and by 1920 had organized more than three-fourths of the industry. In order to consolidate its position and to retain the high rates of wages and favourable working conditions which it had won during the war, the Amalgamated took it upon itself to discover and reduce the wastes of the industry, to control overhead costs, and to raise the efficiency of its own members. It has

undertaken to assist manufacturers in organizing new shops; it has assumed many of the functions of supervision and management thereby reducing the costs of overhead; and it has even made loans to manufacturers. The test of the success of this policy lies in the growth of the Amalgamated

The widening of the sphere of labour activity has not taken place in the methods of collective bargaining alone Reaction to the economic effects of the World War and to the new ideas current then led organized labour to a much broader conception of its goals and methods Out of this period grew the discussion of workers' control, the actual experiment in the Rock Island Arsenal, and the concrete proposal for labour's participation in the management of the railroads, in the form of the well-known Plumb Plan At the same time organized labour began to show a strong revival of interest in co-operative undertakings, culminating in 1920 in the beginning of the labour banking movement They grew rapidly in number and in resources and by the middle of 1926, 36 labour banks had accumulated resources of more than $127,000,000 Soon thereafter the leaders of the labour banking movement, the Brotherhood of Locomotive Engineers, found that their banks had not been wisely managed and were forced to undertake a drastic reorganization of their financial institutions The general movement suffered from these disclosures By June 1928, the number of labour banks was 28 and their resources $114,000,000 With a few exceptions, the majority of the labour banks no longer retain those features that distinguish them from private banking institutions The exceptions, however, are making a valuable contribution to the development of co-operative banking in the United States.

Unions have meanwhile turned their attention to other economic activities. Both the Electrical Workers' Union and later the American Federation of Labor have organized labour co-operative insurance companies that appear to be growing rapidly. The Amalgamated Clothing Workers completed in 1927 a large project in co-operative housing in New York city. Finally a number of unions in the various branches of the clothing industry have created unemployment insurance funds that are entirely novel to American industry. Most of these plans have been shattered by internal dissension in the unions, but the largest, that in the men's clothing industry, now covers some 70,000 members of the Amalgamated Clothing Workers and seems to be a successful and permanent feature of this union's activities

IN OTHER COUNTRIES

As Great Britain was the first country to undergo industrialisation and the modern capitalist system first made its home there, it was natural that modern trade unionism should have sprung into existence in Britain Although in some countries trade unionism has departed from the British model, yet the trade union movement in Britain has powerfully influenced developments elsewhere.

In most countries there has been much the same struggle as in Britain, and the process of development has broadly followed the same lines The French Revolution and the Napoleonic legislation which followed it finally destroyed the guild system in Europe. The rise of large scale industry coincided, as in England, with an era of individualism during which combination was held to be a crime, and was severely punished. In time, however, these penal measures became more or less inoperative, and during the second half of the 19th century in most European countries, and in the 20th century in Russia, the laws prohibiting combination for trade purposes were repealed.

In Germany freedom to form associations was not conceded until the latter half of the 19th century. Under the Empire, though trade unions had no status in courts of law, freedom of association was granted. The trade unions increased in power and membership with the establishment of the Republic, the Constitution specifically granted freedom of association to all, including civil servants, and the unions were called upon to co-operate in the economic activities of the State.

In France the story is broadly similar. During the French Revolutionary period association was prohibited. Later there followed a period of *de facto* tolerance of combination Association ceased to be "a penal delict" in 1864, combinations became finally legal in 1884, and in 1901 an Act of wide scope proclaimed general freedom of association. In 1919 and 1920 legislative powers were conferred on industrial associations to conclude collective agreements, to take legal action to secure the enforcement of agreements. and to take proceedings in respect of infringements of labour laws.

The development of the activities of trade unions has pursued broadly the same course in all countries, though the law with regard to strikes, blacklists, the boycott, etc, varies in different States Generally, trade unions have concerned themselves with the organisation of workers within their ranks, and with industrial negotiations. Where the latter fails, they have made themselves responsible for controlling the withdrawal of labour They have provided "friendly benefits" of certain kinds for their members. In course of time the trade unions came to exercise in varying measure an influence on managerial control in industry, and in most countries influence in some degree social and industrial legislation. In Russia, the trade unions occupy a privileged position During the earlier stages of the Soviet rule, they were a constituent part of the State Though the State and the Unions are now independent, the latter still enjoy legal powers which are an effective influence within the State In Italy, since the establishment of the Fascist régime there has been a very close connection between trade combinations and the State through the Ministry of Corporations Certain duties have been devolved upon the unions, which are in effect direct organs of the State (*See* FASCISM) In Spain, where the course of action was inspired by Italian legislation, corporations were set up by order of the authorities to bring together various trades and industries, and the joint commissions of workers and employers which go to form the corporations include members nominated by the State

In many countries there is a tendency to encourage and to recognise the principle of joint representation of workers and employers on State bodies—a tendency seen in the Joint Industrial Councils in Great Britain Organised employees and employers are represented on the International Labour Organisation, and the right of association is guaranteed by the Treaty of Peace

Socialist ideas were in many countries an important factor in giving a constructive purpose to the trade union movement. In France, the influence of Socialist doctrines in developing the aims of trade unionism is clearly seen, though in the opening years of the 20th century, there was a break between the Socialist Party and the Confédération Générale du Travail, and the latter body at its Conference in 1906. whilst affirming that it included "all workers consciously taking part in the struggle to abolish the wage-earning system and the employers," declared that it stood "apart from all political schools of thought."

In Germany, so long ago as 1854 a Federal Council decree was directed towards the dissolution of all unions pursuing Socialist aims. The Anti-Socialist Act of 1878, though not aimed at the trade unions, did as a matter of fact, result in the dissolution of a number of organisations. At the present time however, the great majority of the trade union membership in Germany belongs to the Socialist trade unions.

In Belgium again, the close association of the political and trade union elements has been one of its chief characteristics, and the Trade Union Committee, which was set up by the Socialist

Congress in 1898, controls the bulk of the trade union membership.

One striking difference between what may be called the British type of trade unionism and the continental type is the intrusion of religion into the movement in some European countries. In the three countries referred to, the trade union movement is divided not only by political differences, but by religious differences. For example, in Germany the trade unions fall into clearly defined groups—the General Federation of Trade Unions (comprising the Socialist unions), the three federations of Christian workers (the German Federation of Christian Trade Unions, the Federation of Salaried Employees, and the Federation of Unions of Civil Servants) and the Federation of National Trade Unions (which repudiates Socialism). There is also a Communist Union of Hand and Brain Workers. At the end of 1925 the General Federation of Trade Unions had a membership of 4,182,511; the Christian unions claimed 582,319 members, and the national unions 157,571 members

In France the Confédération Générale du Travail about the same time had a membership of 553,770. The Confédération Générale du Travail Unitaire, which has been a prey to Communist controversy, was credited with 505,000 members, whilst the Confederation of Christian Workers was reported to have a membership of approximately 120,000.

In Belgium in 1925 the Trade Union Committee had a membership of 594,988, the Christian unions about 180,000, whilst the neutral unions contained only a few thousand workers.

World Growth of Trade Unionism.—As regards the general growth of trade union membership in recent years, it may be said that with the opening of the 20th century trade unionism had secured a permanent foothold in all industrialised countries, and made considerable headway even in other countries In the years immediately prior to the World War, trade union membership was on the increase National laws governing trade union activities varied from State to State and, therefore, the protection afforded by the unions to the workers varied to some extent; but in nearly every country for which particulars are available, there was in the pre-war years a steady and substantial advance in strength as the table given below indicates.

The table shows the growth of membership in over 20 countries from 1910 to 1919 and covers all the most important countries in the world except Russia, where figures are not available for the pre-war years, and China, Japan and India, where trade unionism was little developed before the War

Reliable estimates are available for the following 20 countries (United Kingdom, Germany, U S.A , France, Italy, Belgium, Holland, Denmark, Sweden, Norway, Finland, Switzerland, Spain, Austria, Hungary, Czechoslovakia, Canada, Australia, New Zealand and Serbia). The total trade union membership was at the end of 1910, 10,835,000; 1914, 13,222,000, 1919, 32,680,000.

In most countries during the first part of the war the growth of trade unionism was checked. The decline was substantial in Germany, Austria, Hungary, Italy and Czechoslovakia, but in these countries the numbers began to increase in 1917. After the end of the war numbers increased rapidly, especially in the Central European States

In Europe the total membership at the end of 1919 was at least 26,000,000 as against about 8,500,000 at the end of 1910.

In the 30 countries of the world for which information is available the total membership in 1919 was 42,040,000, and in 1920, 48,029,000. If we take the figures for 1919, no less than 80% of the trade union membership belonged to European countries Of the remaining 7,979,000 members outside Europe, 5,985,000 belonged to the North American continent. Six countries—Germany, Britain, the United States, Russia, France and Italy accounted in 1919 for 33,500,000 members, whilst the remaining 24 countries accounted for only 8,750,000. Two-thirds of the total trade union membership was concentrated in four western countries—Great Britain, the United States, France and Germany

Membership of the International Federation.—This, broadly, represents the position up to date. The total figures have, however, fallen practically everywhere, as will be seen from the typical figures given below, showing the membership of the International Federation of Trade Unions in recent years

The history of trade union efforts at international organisation has been a history of struggle against the difficulties inherent in any attempt at international organisation and of conflicts of principle. The conflict between Marxian Socialism and Anarchism which split the First International has had its counterpart since the war in the clash between Social Democracy and Communism Prior to the war there were two international Labour organisations—the Second International which was political in its aims, but which admitted trade unions into affiliation, and the International Federation of Trade Unions which received that title in 1913 superseding the International Trade Union Secretariat founded in 1901 (*See* INTERNATIONAL)

When the World War broke out in 1914, both the Internationals broke under the strain In order to maintain some sort of connection between the trade unions of the belligerent countries a temporary bureau of the International Federation of Trade Unions was established at Amsterdam, and unsuccessful attempts were made to convene international conferences of trade union representatives of all belligerent countries. A conference of trade union representatives from the allied countries was, however, held in Leeds in July 1916. It was decided to open an international correspondence office at Paris for the duration of the

Membership of Trade Unions at the End of the Years 1910–19

*Figures not available.

war, and a peace programme was formulated In October 1917, a Conference convened by the Swiss Federation of Trade Unions was held at Berne, which was attended by representatives from the neutral States and the Central Powers.

The International Federation of Trade Unions (the I.F.T.U.) was reconstituted in 1919 following a Congress held at Amsterdam It consists of the various national central trades union organisations affiliated, but the General Council includes three delegates from the "international trade secretariats," (*i e*, representatives of the "trade internationals" such as the International Miners' Federation). The management of the I.F T U. is vested in the executive committee, the General Council and the Congress The Executive Committee (or the Bureau, as it is often called) consists of the officers (*i e*, the president, vice-presidents and secretaries) and meets six times a year. The General Council (often referred to as the Management Committee) is a larger and more representative body. The supreme governing authority is the Congress which consists of the General Council and the representatives of the affiliated national centres (*e g.*, the British Trades Union Congress)

The membership of the International Trade Secretariats is as follows:—

The International Trade Secretariats on December 31st, 1925, and 1926

International trade secretariats	December 31, 1925			December 31, 1926

In 1924 the I.F.T U. created an International Committee of trade union women which held its first meeting in November, 1925, and international conferences are held on questions specially affecting women workers.

The total affiliated membership of the I F T U is given in the appended table (p 389).

Communist Movement.—It is now necessary to turn to the Communist trade union movement which owes its origin to the Communist International The germ of this International is to be found in the Zimmerwald Conference of 1915 called by the Italian Socialist Party, and attended by Scandinavian, Dutch, Russian and other Socialists from Eastern Europe, and also by representatives of the pacifist sections of the French and German Socialist movements This Conference was inevitably an anti-war gathering, but when it re-assembled in the following year at Kienthal it was less pacifist than revolutionary It was in a sense the forerunner of the Third (Communist) International, and indeed at a Conference in 1917 definitely declared the need for a new International From this time onwards the Bolshevik Revolution provided an inspiration for revolutionary elements in most countries. The first Congress of the Communist International was held in March 1919, and was convened by the Russian Communists, the Hungarian Communists, the Norwegian Labour Party and smaller Communist groups. In the following year a second Congress met at Moscow and adopted a constitution The aim of the Moscow International is "to organise an armed struggle for the overthrow of the International Bourgeoisie and the establishment of an International Soviet Republic "

The Red International of Labour Unions (the R I L U.) was established at this second Congress, at which minority trade union representatives from various countries were present, when it was declared that "it is the duty of the working class to gather together all trade union organised forces with a powerful revolutionary class association, which, working shoulder to shoulder with the political organisation of the Communist International of the proletariat and in closest contact with this organisation, would be able to develop all its forces for the general victory of the social revolution, and the establishment of a world Soviet Republic " It was also laid down that the International Federation of Trade Unions "because of its programme and tactics" could not "secure the victory of the proletarian masses in all countries " The first R I L U congress was held in July, 1921, in Moscow, and has since continued its work in close association with the Communist International. Relations between the I F.T U and the R I L U have been hostile The British Trades Union Congress, however, endeavoured to bring about an understanding, though without success.

It is not easy to ascertain the real strength of the affiliated membership of the R I L U, but Losovsky, the secretary of the Red International, has analysed its membership as follows (*see* "The World's Trade Union Movement," 1925, pp. 244–5):—

"The Red International of Labour Unions has eight types of affiliated organisations —

1. National trade union centres embracing the whole trade union movement of their respective countries, such as Russia, with 6,400,000 trade union members; Bulgaria, 40,000, Greece, Egypt, 50,000; Persia, 20,000; Estonia, 25,000 and so on.

2. National trade union or regional revolutionary centres existing parallel with reformist centres and carrying on a struggle against them, our organisations being stronger than the reformist ones. Such are, France, with 480,000 members; Czechoslovakia, 300,000; Yugoslavia, 100,000; Java, 35,000 and so on

3. National trade union centres playing a small rôle in comparison with the reformist trade union movement of their respective countries as in Holland with 20,000 members; Belgium, 12,000; Germany, 150,000; the United States, 25,000, and so on.

4. National trade union centres identifying themselves with the principles of the R I.L U., but not affiliated thereto, as a result of the 'White Terror,' as is the case in Finland, 50,000; Rumania, 60,000; and so on.

5. Independent unions and unions which have been from time to time formed of expelled members not belonging to the national

(1) Including 119,524 young workers, not mentioned under the heading "Men and Women" (2) Including 2,124 members not mentioned under the heading "Men and Women" (3) Including 1,336,303 members not mentioned under the heading "Men and Women" (4) Besides 10 local mixed unions (5) 28 different trades distributed over Tel-Aviv, Haifa, Jerusalem, Tiberias, Afuleh and Akko (6) Membership not to be given (7) Including 124,601 young workers not mentioned under the heading "Men and Women," and 80,216 members for whom affiliation fees were paid to the General German Civil Servants Federation. (8) 54 local unions. (9) Dec. 31, 1925. (10) Including 1,185,834 members not mentioned under the heading "Men and Women"

trade union centres of their respective countries

6. Minorities inside the reformist trade unions organised under the direct leadership of the Communist faction; Germany, Japan, Italy, Sweden, Denmark, etc.

7 Opposition blocs or minority movements co-ordinating the action of all left-wing elements both inside and outside the reformist and the Anarcho-Syndicalist unions of such countries as: the United States, Great Britain, Spain, Austria, the Argentine, Mexico and elsewhere.

8 Finally, there are the left-wing elements belonging to the unemployed committees (Great Britain), shops stewards committees, etc, generally supporting the R.I.L U. policy."

The Fourth Conference of the R I L U held in 1928 was attended by 421 delegates, representing 49 national groups, and according to the leaders of the R.I.L U., the affiliated membership is approximately 19 millions, comprised as follows —

U S S R.	10,200,000	United States	388,000
China	3,000,000	Czechoslovakia	210,000
Germany	1,000,000	Australia	120,000
Great Britain	700,000	Cuba	100,000
France	525,000	Poland	95,000
Mexico	93,000	Canada	10,000
Sweden	80,000	Latvia	9,000
Colombia	60,000	Japan	8,000
Chile	50,000	Argentina	7,000
Brazil	40,000	Mongolia	7,000
Norway	33,000	Hungary	5,000
Korea	30,000	Uruguay	4,500
Dutch East Indies	25,000	Portugal	4,000
Serb, Croat, Slovene		Estonia	3,000
Kingdom	21,000	Denmark	2,000
Peru	20,000	Venezuela	1,200
Italy	12,000	Guadeloupe	800

These figures include the membership of minority groups within trade unions which are affiliated to the I.F.T.U.

It will be seen that no national trade union body representing the whole of the organised workers of any country, apart from Russia and certain small countries where trade unionism is an ineffective force, has associated itself with the R I L U, and that outside Russia its chief support comes entirely from individual trade unions and minority groups, though Losovsky is at pains to point out that the figures of membership of the I F.T.U are swollen by the adherents of the R I L U

BIBLIOGRAPHY.—The International Federation of Trade Unions publishes Reports, a Year Book, and serial publications ("The International Trade Union Review" [Quarterly], and "The International Trade Union Movement" [Monthly]) It also publishes a series of volumes on trade unionism, *e g*, C Mesten's "The Trade Union Movement in Belgium" (1925). For the Communist side of the Movement, *see* A. Losovsky, "Trade Unions in Soviet Russia" (1920), and "The World's Trade Union Movement" (1925) Other special studies are S Sanders, "Trade Unions in Germany" (1916) and W P Ryan, "The Irish Labour Movement" (1920) The most important work, however, is the Report on "Freedom of Association" published by the International Labour Office Three volumes have appeared Vol I (1927), Comparative Analysis, Vol. II (1927), Great Britain, Irish Free State, France, Belgium, Luxemburg, the Netherlands, Switzerland, Vol. III (1928), Germany, Former Dual Monarchy of Austria-Hungary, Austria, Hungary, Czechoslovak Republic, Poland, Baltic States, Denmark, Norway, Sweden, Finland Each section contains a bibliography (A. GR)

TRADE WINDS, the name given to the regular north-easterly and south-easterly winds which blow from the tropical belts of high pressure towards the equatorial belt of low pressure. Their regularity, especially over the oceans, explains their name, the term "trade" being used in the otherwise obsolete sense of "course" (*cf.* "tread"). Their distribution may be considered broadly as being between 3° to 35° N, and from the equator to 28° S, but at any particular period their influence is felt over a narrower area on account of their seasonal swing into higher latitudes during the respective summer seasons of the two hemispheres. The best area for the study of these winds is the Atlantic ocean. (See *Met. Office Publication*, No. 203, also METEOROLOGY.)

TRAFALGAR (trah-făl-gahr′; popularly tră-făl′gar), **THE BATTLE OF.** The British naval victory over the French and Spanish fleets off Cape Trafalgar, on Oct. 21, 1805, was a sequel

to the breakdown of Napoleon's scheme for invading England, and an account of the movements leading up to it, known as the Trafalgar Campaign, will be found under the heading NAPOLEONIC CAMPAIGNS.

Admiral Villeneuve, returning from the West Indies, succeeded in making the port of Ferrol; thence he should have sailed for the Channel and effected a junction with the Brest fleet, but, judging that Napoleon's schemes were already defeated, he made for Cadiz instead Nelson, after his arrival at Gibraltar from the West Indies, had fallen back on the English Channel fleet, but Collingwood was watching Cadiz with three ships. On Villeneuve's arrival, he retreated slowly towards the Straits, and the French pursued him; but they had no wish to be drawn into the Mediterranean, and after a time retreated to Cadiz, and Collingwood was able to resume his station; he was joined at the end of August by reinforcements amounting to 22 ships. The importance of defeating or effectively blockading this allied force which now numbered 33—15 of them Spaniards—was fully realised by the Admiralty, and in September they decided to send Nelson to take command of the blockading force

Nelson in Command at Cadiz.—Nelson left Portsmouth on Sept. 15 with three sail of the line, arriving off Cadiz on the 29th of the same month—his forty-seventh birthday. He had sent ahead a frigate to forbid any hoisting of colours or firing of guns, in order not to draw the attention of the Allies to the arrival of British reinforcements But the unofficial welcome he received was such as to put heart into any commander of a fleet. During the first fortnight of October he was reinforced by a further six ships, so that his strength was at one time 34, but at the time the battle was actually fought he had only 27 ships at his disposal, six had been sent to Gibraltar to revictual, and Admiral Calder, who was going home to face court-martial for his unsatisfactory action off Finisterre, was magnanimously allowed to return in his flagship. Nelson did not keep the bulk of his fleet close to Cadiz; only the frigates were inshore, most of the ships being some 30 to 40 miles to sea, connection being maintained by a line of signal ships.

Villeneuve Ordered to Mediterranean.—Nelson's first task was to induce Villeneuve to put to sea, and this was performed for him by Napoleon himself A new coalition of European powers had just been formed against Imperial France, and Napoleon, unable to use his troops against England owing to the breakdown of his schemes, had marched them against Austria He thus required naval support in the Mediterranean, and Villeneuve was ordered to leave Cadiz and enter that sea, furthermore, should he encounter an enemy fleet to which he was not inferior, he was not to hesitate to attack them These commands reached the French Admiral at the end of September. He knew, however, that they could never be acted on successfully, and a council of war held at the beginning of October decided that, though a sortie might be possible, to give battle to the British fleet would be suicidal At this time, too, it appears that the Allies were under-estimating the strength of the British Later in the month Villeneuve heard that Napoleon was sending Admiral Rosily to supersede him This he regarded as a reflection on his honour, and he decided to put to sea before his successor arrived He did not intend to give battle to Nelson if he could get into the Mediterranean without doing so, but he fully realised that he would probably be forced into action; and he thought that, in such a case, Nelson's probable plan would be to obtain local superiority over part of his fleet. To guard against this he formed a reserve squadron of 12 ships under the Spanish Admiral Gravina, which was to keep to windward of the rest of the fleet, and thus be able to come to the assistance of any part of it that was in difficulties.

Nelson's Battle Orders.—Nelson had also drawn up orders for the guidance of his officers, and had explained to them how he intended to fight the battle His instructions are embodied in the "Nelson Memorandum," which was drawn up at a time when he expected to have a larger force than 27. None the less the principles it contained are applicable with equal force to a smaller fleet. They were that the attack was to be made in two bodies; the larger, under Collingwood, was to obtain local superiority over the enemy's rear, while Nelson, with the smaller body, was to preserve him from the interference of the van and centre, should they attempt to go about to the assistance of the rear, as they normally would. On the day of battle Collingwood's squadron consisted of 15 ships and Nelson's of 12.

Villeneuve Puts to Sea.—It was on Saturday, Oct. 19, that the first of the Allies got to sea. Nelson knew of their movements immediately, and made sail for the south-east so as to cut them off from passing through the Straits. Only part of the allied fleet got to sea on the Saturday, and on Sunday the 20th the weather was so bad that they returned to the neighbourhood of Cadiz. Nelson, throughout, kept his main fleet out of sight, but followed them, move for move, receiving all the information on which he based his decisions from his frigates. Monday the 21st was a fine day, the wind was light and blowing from the north-west, and at dawn the two fleets were in sight of one another The Allies were sailing south, making for the Straits again, and the British were some 12 miles to the west of them Nelson at once ordered his fleet to form two lines of sailing, in accordance with his plan outlined above His own squadron was the more northerly of the two, and each admiral was leading his own squadron, Nelson in the *Victory*, and Collingwood in the *Royal Sovereign* In this formation, they approached the allied fleet, and as they came more clearly into view, Villeneuve, for the first time, saw that he had underestimated their strength He at once sacrificed the originality of his dispositions by ordering Gravina, with the reserve squadron, to come into the line, and, shortly afterwards, partly with a view to keeping Cadiz open as a refuge on his lee, and partly to counter what he thought was designed as an attack on his rear as he was sailing south, he ordered his whole fleet to wear and sail roughly north

Collingwood's Attack.—Villeneuve's order to his fleet to wear was made about 8 o'clock, and it was not properly finished when Collingwood, who was to initiate the attack, ordered his squadron to change its formation from an irregular line ahead to an irregular line of bearing This was about 8 50, some two hours after Nelson had first ordered the advance Collingwood's object was to bring his force into a line as nearly parallel as possible with the part of the enemy line that he was to engage, and the concavity in their line was such that this manoeuvre would virtually produce that result Nelson had given his second-in-command a free hand in deciding how to carry his line into battle, so that the credit for this movement, admirably suited as it was to the circumstances and designed to enable the British ships to use their broadsides as they got into action, must be given to Collingwood For the rest, he carried out brilliantly the part assigned to him—namely to break through the enemy and engage the rear 12 ships. His own vessel, the *Royal Sovereign*, being a very fast sailer, was in close action just after 12 o'clock, and to her fell the duty of selecting the gap which would enable him to cut off 12 ships. Actually he cut off 15 and became engaged with 16

Nelson's Attack.—It now remains to consider the movements of Nelson's line The commander-in-chief it will be remembered had kept for himself the duty of preserving Collingwood from any interference from the allied centre or van. For this purpose he continued his advance in the order he had first assumed, that is to say, irregular line ahead With the object he had before him, he naturally wished to disguise the point at which his attack was finally to be directed, and line ahead was the most flexible and easily-managed formation he could adopt It had the drawback of exposing the head of the line, as it approached, to the concentrated fire of the enemy, but Nelson was prepared to regard this as a justifiable risk in view of the advantage of flexibility which the formation conferred, and which was peculiarly valuable in the particular circumstances The event proved him right. He began by aiming at the van rather than the centre of the allies, whose leading ships, nervous of having their T crossed, crowded on sail to prevent this manoeuvre being executed, thus taking themselves further from that part of their line which was now being attacked by Colling-

wood, and which Nelson did not intend should be assisted by them. Indeed, the whole of the allied van and centre, mystified by Nelson's movements and uncertain of his aims, could do nothing but wait for him to declare his intentions, while they left the rear to look after itself. Nelson was himself leading his line, and as the *Victory* approached the allied van, he turned to starboard, followed in succession by the ships in his squadron and sailed down the allied line, looking for a suitable place at which to break through. This turn enabled him to open fire, but he preferred to hold it. Finally he found a gap astern of the *Bucentaure*, twelfth ship in the line and Villeneuve's flagship, and, passing through, he opened fire, raking the ships on either side with terrible effect. The majority of his line deployed to starboard and broke through the Allies at various places between the points pierced by Nelson and Collingwood, but two more ships ahead of the *Bucentaure* were engaged, the leading ten ships finally being left without attention Six of these, under Dumanoir, at length made some attempt to go about to the help of those behind them, but their arrival was too late to be of any use, and they made off; for, in the meantime, Nelson's 12 had been matched with 7, with the inevitable result. By this time, too, victory had declared itself for Collingwood, who had been left without interference, as Nelson had designed, to complete the destruction of the rear

Completeness of the Victory.—In all, 20 prizes were taken—about 60% of the allied fleet A larger percentage was taken or destroyed at the Nile, but the comparison is not a sound one, for at the latter battle the enemy were caught in a confined space At Trafalgar they had plenty of room to manoeuvre and a friendly port on their lee; yet they could not escape, such was the paralysing effect of Nelson's tactics—an inspired mixture of the traditional and original. Nelson had solved a problem that had puzzled British admirals for a century—namely, how to prevent the French making off while most of their fleet was still more or less intact. For this reason Trafalgar is regarded as the greatest of naval battles, and Nelson as the greatest of Admirals.

TRAFFIC AND TRAFFIC REGULATIONS. Throughout the civilized world the countryman is being irresistibly drawn towards the great cities, which spread outwards, ring by ring, over the open fields, while the ancient core of the city on which millions of workers now converge retains the shape imprinted on it in mediaeval times when a small compact area amply sufficed

IN GREAT BRITAIN

London.—Although the difficulties thus created are by no means restricted to Greater London, where the population had risen from 7¼ millions in 1911 to 7¾ millions in 1925, yet it is probably within this area that the typical problems present themselves in the most aggravated form In 1923 the registrar-general published, for the first time, a report on the work-places of residents in London and the five home counties. The preface reminds us that in a less highly organized and industrialized society localities may be self-sufficient, every residential group being supplied with its needs by members of the same groups in their working capacity Such conditions were due to the dispersion of necessary service and production, which in the absence of transport facilities had to be located in proximity to the population served The subsequent development of transport and communications fostered a concentration which has changed the whole face of industry.

To gauge the magnitude of the traffic problem the following data may be of service. In 1912 a census was taken of vehicles of all classes passing 39 of the more congested points in London between the hours of 8 A.M. and 8 P.M. on a selected day The total reached was 825,445. In 1927 a count taken at the same 39 points gave a total of 1,139,434, an increase of 38%. The outstanding feature on the London streets is the motor-omnibus, of which in 1913 the number licensed was 3,664 In July 1927 the number of motor-omnibuses scheduled for regular operation in the Metropolitan Police District was 4,709. In 1913 the passengers carried by omnibuses numbered 736,000,000; in 1924, 1,485,000,000; while in 1926 a total of 1,700,000,000 was computed to have been reached. The important part played by the London County Council's tramways can be estimated from the statement that their tramcars carry more than 1,000,000 passengers during the six busiest hours of the day. On the Victoria Embankment 400 tramcars pass every hour.

Expressed in millions the numbers of passengers carried by the various forms of transport in London have been estimated as follows —

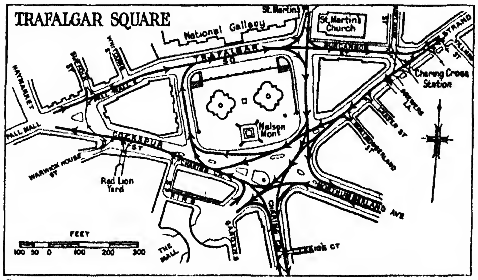
Year	Suburban trunk railways (estimated)	Underground	Tramways	Omnibuses	Total
1913	450	298	812	736	2,296
1919	505	480	1,064	861	2,910
1923	488	367	1,001	1,214	3,070
1924	474	369	983	1,485	3,311
1925	.	289	984	1,687	2,960
1926		281	965	1,700	2,946
1927	478	315	1,011	1,842	3,646

In 1927 a grand total of 3,646,000,000 was reached The increase in the volume of traffic is out of all proportion to the growth of population A principal factor in the increase of congestion on the streets is the growth and spread of the travel habit. It has been estimated that whereas in 1900 every Londoner, man, woman and child, travelled 158 times a year, that figure had risen in 1925 to 460 The burden thus thrown upon the transport agencies is even greater than these figures would indicate, owing to the fact that the "peak" periods of the day are now more compressed

Remedies.—The remedies for traffic congestion on the streets are easier to enumerate than to apply First and foremost, all wanton obstruction should be removed; fountains, clock-towers, refuges, obelisks, horse-troughs and such like structures erected in the leisurely days of an earlier century must justify their existence in the light of changed circumstances Street traders and stalls must be relegated to side streets, slow and heavy vehicles must be prohibited from using, during the busy hours of the day, certain routes in which rapid movement is indispensable; the position of the great markets must be reconsidered in order that the streams of ponderous traffic to which they give rise may not choke all-important adjacent arteries By extending railway sidings into markets, now served by road, much of the congestion on the latter might be relieved The provision of adequate parking places or stances will prevent the wasteful occupation of valuable space in busy thoroughfares by stationary vehicles Within the London Traffic Area it is probable that upwards of eighty parking places will eventually be in use under regulations made by the Minister of Transport.

Parallel Routes.—A useful purpose may be served by the judicious sign-posting of parallel routes, so that inexperienced drivers may be induced to leave the overcrowded roads and make use of less familiar thoroughfares A glance at the map of our great cities will show how many such alternatives are already available and how many more might be rendered feasible by the demolition of a few buildings which interrupt the continuity of a line of streets In many instances greater advantage would accrue from the completion of an alternative route by the acquisition of such obstructive buildings than from the customary widening at enormous cost of the principal thoroughfare by the demolition of one entire frontage. Two roads are better than one, seeing that an accident may at any time have the effect of closing a single thoroughfare, however wide. Unavoidable traffic stoppages due to road repairs can be shortened in many cases by the use of quick-setting cements and the introduction of pneumatic

tools for breaking up old foundations. In the busiest thoroughfares repairs should proceed uninterruptedly day and night. Co-ordination between adjoining highway authorities would prevent the annoyance of parallel routes being simultaneously closed for repair The extreme need of some co-ordinating body for London led to the creation in 1924 of the London and Home Counties Traffic Advisory Committee, which reports to the Minister of Transport upon all matters affecting transit in that populous area.



PLAN OF TRAFALGAR SQUARE, LONDON, SHOWING SYSTEM OF "ROUNDABOUT" TRAFFIC INTRODUCED TO RELIEVE CONGESTION

High-level Roads.—To relieve the congestion at the ground-level of great cities the construction of high-level roads may before long be forced upon civic authorities

Single-way Traffic.—Narrow streets which are so situated as to form useful lines of communication can often be advantageously utilized as single-way routes, a practice which has been widely adopted in Paris, where no less than 105 streets are reserved for one-way traffic In London this restriction has been applied to 45 streets Obviously the facilities for establishing alternative routes and single-way routes are greatest in cities which have been methodically laid out on a fairly rectangular plan In cities of haphazard growth more formidable difficulties arise. The delay inflicted upon traffic at busy cross roads can be eliminated by the enforcement of gyratory movement in the rare cases where space permits, or by the construction of a bridge or tunnel enabling one stream of traffic to pass over the other—a device that is only rendered feasible by a convenient configuration of the ground The ample dimensions of the "places" of Paris have enabled gyratory movement to be instituted at 19 traffic centres, whereas in London the experiment was tried in Jan 1926, for the first time, in Aldwych and Parliament Square where its success has led to its extension to 10 other traffic centres (*See* figure illustrating the arrangement prescribed for Trafalgar Square) At 14 important road intersections where space for gyratory movement is lacking the regulation is imposed that vehicles shall not turn to the right By this means the steady flow of traffic is promoted

White lines formed by metal plates sunk into the pavement or by similar devices play an invaluable part in directing traffic into its proper channels The acceleration of vehicular traffic due to the adoption of these various methods of control renders it necessary to indicate special crossing places for pedestrians In great cities the construction of subways or bridges for foot-passengers is likely to be increasingly favoured where funds permit

Traffic Signs.—An experimental installation of light signals was brought into use in London at the junction of St. James's Street and Piccadilly in 1926 These signals, eight in number, are electrically operated from a central control at the junction of the two streets They are of the three-aspect colour-light type, fitted with red, amber, and green lenses, with the necessary transformers, and are mounted on tubular steel posts on cast iron bases. Five of the signals are fitted with a small lens which serves as an indication to the constable on point duty that the signal is showing red The central control cabin is equipped with an illuminated diagram which repeats all signal aspects and with a miniature frame of eight levers, space being provided for the addition of a king lever, if necessary Each of the levers has three positions—normal, mid-stroke and reverse—providing red, amber and green indications, respectively.

Circumferential Roads.—Whatever efforts may be made to take full advantage of the roads already in use, the vast increase in vehicular traffic will in most of our growing cities call for the provision of additional thoroughfares While the radial roads may be tolerably adequate it will usually be found that suitable circumferential roads are wanting, save in the case of towns whose fortifications have given place to a ring road Relief to the congested centre of a city can often be most readily afforded by the building of circular roads which enable traffic to pass round the outskirts. By suitable regulations it should then be possible to limit the passage through the crowded centre to vehicles whose business legitimately requires their presence there. Little hardship is inflicted upon drivers who are relegated to the circular road, seeing that, although their journey may be longer, the time occupied is less, owing to the absence of congestion. As a good example of this type of route may be cited the circular road, 26 m. long, round the north of London

Co-ordination.—At the root of the traffic problem in great centres of population lies the difficulty that the present local government boundaries usually have no relation whatever to the wider traffic region upon which the welfare, the work and the very existence of the city depend. Concerted action for the common good is defeated by the multiplicity and divergent interests of the small administrative units which encircle the city In the aggregate the resources of the greater community forming the traffic region are amply sufficient to provide the remedies which are admitted to be necessary, but the application of these resources to the desired purpose is difficult in the absence of some public body empowered to determine the best means of promoting improvement schemes and to apportion the cost over the traffic region which ultimately benefits Until this power of apportionment can be exercised there are insurmountable obstacles to the execution of vital improvements in poverty-stricken administrative areas, where local conditions often generate traffic delays reacting injuriously upon the whole traffic region An authority exercising control over such a traffic region would naturally be charged with the duty of co-ordinating the different traffic agencies and means of transit, so as to eliminate wasteful competition and the congestion to which it gives rise Certain routes would be reserved for trams or trolley vehicles, others for motor-buses, others for underground railways The number of vehicles plying on various routes would be restricted to the needs of the travelling public instead of being dependent upon the varying fortunes of the struggle between rival undertakings It is indeed questionable how much longer the interests of the citizen can tolerate the use of the public highway as the arena for unrestricted traffic-competition The London and Home Counties Traffic Advisory Committee in their report for 1926–27 reiterate their view "that the co-ordination of passenger transport services with a common fund and common management with the elimination of unnecessary, wasteful and uneconomic competition is essential before any substantial improvements in travelling facilities can be effected "

The need for additional resources is acutely felt by congested suburban railways constructed in the days of steam traction Electrification of such lines is often the only means of increasing their carrying capacity and great activity prevails in the application of this remedy. As an instance may be quoted the electrification of the London suburban lines of the Southern Railway, involving the conversion of 650 m of track, at a cost of nearly £8,000,000. The traffic flow of a railway being governed in large measure by its terminal capacity, the aim must be to enable the largest number of trains to enter and leave the terminal It has been claimed that thanks to electrification the capacity of terminals can be increased by 150% so that five trains would run where two ran formerly (*see* RAILWAYS. *Electrification*).

Future Developments.—Casting a prophetic glance forward one can discern certain directions in which the development of civic, social and industrial life may be fundamentally affected

by the pressure of the traffic problem There is already a tendency towards the creation of self-contained satellite towns of moderate size where the citizen can live within an easy walk of his work and yet within sight of the green fields Such development will be fostered by the North Orbital Road which is being planned to sweep in a curve 75 miles long through the counties of Essex, Hertfordshire and Buckinghamshire, at a distance of about 20 miles from Charing Cross. The administrative centres of capital cities can be relieved by moving to the open outskirts of towns certain offices and departments which do not require an absolutely central position As open spaces in central districts become rarer and rarer we may see legislation promoted to safeguard such squares and gardens as have escaped the builder

It is conceivable that the high rental value of office accommodation in the heart of great cities and the increasing closeness of business contact between countries of every latitude may lead to the continuous use of offices throughout the day and night, with the result that the volume of passenger traffic to and from the suburbs would be better distributed It is perhaps significant that several London restaurants should remain open throughout the 24 hours A time may indeed be in sight when the problem of transport will be the dominating influence in moulding the life of the citizen in every highly developed industrial community

(H My)

THE UNITED STATES

The increase in numbers of motor cars has created very serious traffic problems that demand drastic treatment for their solution. They attain their maximum of seriousness in cities, where owing to the narrow thoroughfares, variable speeds and necessity for frequent and long stops, the resulting congestion has already reached a point where traffic movement is greatly hindered This condition is found at present most emphasized in American cities on account of the vastly larger number of automobiles in proportion to population than is found in other countries Taking the two largest American cities as examples of congestion the following table of motor car registration shows how rapid has been the growth, and how much more rapid than the corresponding increase in population

New York				
Type of vehicle	1915	1920	1925	1927
Passenger	59,850	152,036	365,894	464,180
Commercial	12,148	83,746	114,022	148,363
Total	71,998	235,782	479,916	612,543
Population (in millions)	4 3	5·0	5 00	6
Cars per 1,000	17	47	81	102
Chicago				
Passenger	36,419	86,709	290,956	388,622
Commercial	7,384	22,900	48,262	54,194
Total	43,803	109,609	339,218	442,816
Population (in millions)	1·9	2·4	3·0	3·1
Cars per 1,000	23	50	113	127

Traffic Towers.—In 1918 the congestion on Fifth Avenue, the busiest thoroughfare in New York, had become so great that some means, other than traffic policemen stationed at intervals, were seen to be necessary if a reasonable speed of movement was to be maintained The local situation of Fifth avenue was peculiarly difficult as the nearest parallel street is 920 ft. distant on one side and 420 ft. on the other, thereby forbidding any large diversion of vehicles In that year there was erected a series of signal towers placed in the centre of the street with red, green and white lights operated by hand at each tower, the several operators turning the lights to correspond with those at 42nd street. The towers were taken down in 1929, as occupying too much space

The controlling of vehicular traffic by a system of mechanical signals was extended in New York and has since been adopted with various modifications by every city in the United States and on a growing scale in other countries. As installations were erected and large areas of cities were put under control, traffic engineers found that there were at least three methods under which automatic signals could be operated, (1) the isolated clock, (2) the synchronous and (3) the progressive systems

In the synchronous system all signal colours are changed simultaneously and are the same in a given direction, that is, green or clear lights are shown permitting all north and south traffic to move throughout the controlled area while the red or stop signal is set against the cross, or east and west movement. Then after a fixed interval, the signals and the corresponding traffic movements are reversed The synchronous system is simple in installation and is used in the great majority of cities

The progressive operation undertakes to keep all traffic moving continuously in all directions To accomplish this the street to be controlled is divided into blocks of approximately equal lengths which may be the ordinary city blocks or arbitrary traffic blocks comprising several city blocks according to the intervals between cross streets Instead of having all signals in one street change to the same colour at the same instant as in synchronous operation, in the progressive they alternate That is, when a green light is seen at the beginning of one traffic block a red is shown at the next The block lengths and signal time intervals are so fixed that a driver proceeding at any predetermined speed which is usually set at from 15 to 20 m per hour, will find the next signal turn green giving a clear way as he reaches it

The progressive system can be successfully operated only when the longitudinal and cross timing intervals are equal and it works best on wide thoroughfares with long traffic blocks Narrow streets, particularly those with only one lane of moving vehicles, do not respond well, since the entering of parked cars into the moving lane or other similar irregularities are apt to throw the traffic out of running schedule Under this system all signals are connected to the same set of bus wires and are operated simultaneously. Control apparatus is the same for the progressive and synchronous systems

To obviate some of the disadvantages of the progressive system the flexible progressive or co-ordinated system has been devised, in which the clear signals can be given at irregular intervals on both the through and cross streets and so permit a variation in length of traffic blocks according to relative densities of traffic. Mechanically this system is the most expensive to install and the most complicated in operation A separate electric cable must be run from each intersection to the central station and the signals at each intersection be turned by its individual timing switch. No general rule can be laid down to govern all cities There are many factors that must be taken into consideration among which the following may be mentioned total volume of traffic, relative density of travel in the two directions, widths of streets, street intervals, character of traffic, presence of tramways and control of extraneous retarding causes.

In March 1929 a centralized system installed at one point was put in operation in the city of New York It controlled all of the traffic lights in the center of the city by means of seven machines, one for each of the principal north and south avenues With the addition of about six more it was planned that all of the lights in the island of Manhattan would be controlled One of these machines could do all the work; however flexibility is obtained by the use of one for every avenue Each machine consists of a synchronous motor driving gears and cams making the necessary contacts to operate the relays that in turn control the switches in the circuits to the lamps The cycle of operation adopted is 3 minutes, 115 seconds for north and south movement of traffic, 55 seconds for east and west traffic with two 5 second dark intervals To change the cycle it is only required to replace the motor For any cycle, however, the time interval of red or green light and of darkness can be adjusted at will

Interference with Traffic Flow.—The most important of the last class are left hand turns (in America all traffic is right hand), presence of horse-drawn vehicles and parking Of these the first two are serious interferences with a continuous or progressive flow. A left hand turn involves the crossing of the opposite traffic lane, while the slow speed of horses and heavy trucks will

defeat, unless there be plenty of passing space, a general platoon or group movement at an established speed that approximates one as great as 15 m. per hour. In some cities left hand turns in congested districts are forbidden, but this can be done conveniently only when there are parallel streets sufficiently near so as not to involve too great a loss of time for the diverted vehicles.

Parking.—Parking, however, presents a great problem because it is opposed and supported equally strongly by opponents and proponents. To forbid parking is opposed by some merchants who fear that their customers would be driven away if they were prevented from standing their cars in the street while actually shopping Unless streets be widened at great expense, or some heroic remedy adopted, it is evident that free parking must be radically limited. Already in some cities a time limit is set in many streets, while in very busy streets it is expressly forbidden during hours of maximum congestion to stop a car except to deposit or pick up passengers.

One-way Rules.—The regulation of traffic and the need for full facilities to keep it moving has led to the adoption of one-way traffic. This has worked well and will be more widely introduced as the problem becomes more acute. The installation of traffic signals was expected to reduce the number of policemen engaged in traffic regulation The pressure has however increased more rapidly than the relief so that the demand for men is steadily growing. In New York 581 policemen were so detailed in 1907, 775 in 1917 and 2,511 in 1927 (W. B. PA)

TRAHERNE, THOMAS (1637?–1674), English writer, was, according to Anthony à Wood, a "shoemaker's son of Hereford." He entered Brasenose college, Oxford, in 1652, and after receiving his degree in 1656 took holy orders. In the following year he was appointed rector of Credenhill, near Hereford, and in 1661 received his M.A. degree. He found a good patron in Sir Orlando Bridgeman, lord keeper of the seals from 1667 to 1672 Traherne became his domestic chaplain and also "minister" of Teddington He died at Bridgeman's house at Teddington on or about Sept. 27, 1674. He led, we are told, a simple and devout life and was well read in primitive antiquity and the fathers. His prose works are *Roman Forgeries* (1673), *Christian Ethics* (1675), and *A Serious and Patheticall Contemplation of the Mercies of God* (1699). His poems have a curious history. They were left in ms and presumably passed with the rest of his library into the hands of his brother Philip They then became apparently the possession of the Skipps of Ledbury, Herefordshire.

In 1896 or 1897 they were discovered by W T. Brooke in a street bookstall. Dr Grosart bought them, and proposed to include them in his edition of the works of Henry Vaughan, to whom he was disposed to assign them He left this task uncompleted, and Bertram Dobell (*q.v*), who eventually secured the mss., was able to establish the authorship of Thomas Traherne. The discovery included, beside the poems, four complete "Centuries of Meditation," short paragraphs embodying reflections on religion and morals. Some of these, evidently autobiographical in character, describe a childhood from which the "glory and the dream" was slow to depart The poems on childhood may well have been inspired by Vaughan's lines entitled *The Retreat.* His poetry is essentially metaphysical and his workmanship is uneven, but the collection contains passages of great beauty.

See Bertram Dobell's editions of the *Poetical Works* (1906), and the *Centuries of Meditation* (1908 and 1927); H I. Bell's edition of the *Poems of Felicity* (Oxford, 1910); and G E. Willett, *Traherne: an essay* (Cambridge, 1919).

TRAILL, HENRY DUFF (1842–1900), British author and journalist, was born at Blackheath, London, on Aug 14, 1842, and died in London on Feb 21, 1900. Traill was one of the best known journalists of his day; he was connected with the *Pall Mall Gazette,* the *Saturday Review,* and other papers, and was the first editor of *Literature.* He wrote some important biographical and critical studies, and in 1893–97 directed the production of a vast work on *Social England.* But he is now remembered for his witty parodies and *jeu d'esprit.* His best known work is *The New Lucian* (1884; new and enl. ed., 1900) Traill also wrote one or two plays Nellie Farren made a noteworthy success in his *Glaucus, a Tale of a Fish* at the Olympic theatre in 1865. In collaboration with Robert Hichens he wrote *The Medicine Man,* which was produced in 1898 at the Lyceum.

TRAIN BANDS. In the early part of the 17th century the commissions of musters directed the county officials to muster all persons liable for service and organize them into bands for training. The bands so organized became known as trained bands or train bands, a phrase which by the end of Charles I.'s reign was superseded by the term militia

TRAINING CAMPS. A movement for the military training of youth in the United States through the means of summer camps conducted under the supervision of regular army officers was inaugurated by Maj-Gen. Leonard Wood in the summer of 1913. Two camps, at Gettysburg, Pa., and at Monterey, Calif., were attended by 244 men, most of them college students. The following year (1914) camps were established at Fort Ethan Allen, Burlington, Vt.; Asheville, N.C; Ludington, Mich.; and Monterey, California. The total number in the different camps was 667. These aroused a gradually growing interest, reinforced by considerations growing out of the outbreak of the World War, and the Department of War determined that four such camps should be established during the summer of 1915, at Chickamauga Park, Ga.; Plattsburg, NY. (three camps); Ludington, Mich; and at the Presidio, San Francisco, California. The total number of men who passed through the camps during this year was 3,406. The camps were no longer limited to students from colleges and high schools, but were open to men from all walks of life who had the necessary physical qualifications and showed sound qualities of leadership. As Plattsburg was the largest training centre, the camps, wherever held, began to be called "Plattsburg Camps" In 1916 a series of four camps, each for a month, was held at Plattsburg, NY; a camp of one month's duration for boys at Fort Terry, NY; a series of six camps of two weeks' intensive training at Wadsworth, N.Y., for the police of New York city; and a series of three camps, each for a month, at Oglethorpe, Georgia. Over 16,000 men were passed through the camps. In 1917, applicants for the camps numbered 130,000, and had the United States not gone into the War in the spring well over 100,000 men would have been trained in these volunteer training camps. During the winters of 1915–6 and 1916–7 courses were opened in Boston, New York, Providence, Detroit, Pittsburgh, Philadelphia, and other cities for the instruction and examination of applicants for reserve commissions, and through them were developed a large number of officers who played a vital part in the training of the great War levies.

When the United States entered the World War these hastily but intensively trained, enthusiastic men were invaluable. They formed the nucleus of civilian officers with which to begin the great work of developing 200,000 officers, and added a valuable and indispensable force to the scanty number of regular officers and national guard officers available for the training of men. In the spring of 1917 the Federal Government took over the whole task and established a series of camps for the training of officers for the War. The Secretary of War directed the establishment of 16 Citizens' Training Camps at the following points: Plattsburg Barracks, N.Y. (two camps); Madison Barracks, NY.; Fort Niagara, NY.; Fort Myer, Va.; Fort Oglethorpe, Ga; Fort McPherson, Ga.; Fort Benjamin Harrison, Ind. (two camps); Fort Sheridan, Ill. (two camps); Fort Logan H. Roots, Ark.; Fort Snelling, Minn.; Fort Riley, Kans.; Leon Springs, Tex.; Presidio of San Francisco, California. The training camps for officers were ordered to be ready for the reception of reserve officers about May 8, for candidates for commission May 14, and the course of instruction was to begin on May 15 1917. The minimum age for attendance was 20 years and nine months; the maximum age, 44 years. In addition to the foregoing, General Order 119, War Department 1917, established a training camp at Fort Winfield Scott, Calif, for the training of members of the coast artillery section of the Officers' Reserve Corps residing within the territorial limits of the western department, and a similar camp at Fort Monroe, Va., for the balance of the coast artillery reserve corps officers. These training camps began opera-

tion on Sept. 22, 1917. A medical officers' training camp was also established in 1917 at Camp Greenleaf, Fort Oglethorpe, Georgia. Other camps for officers were established at the headquarters of the various divisions, the courses being essentially the same as those at the former officers' camps. The period allotted for the development of an officer at the government training camps was three months. The work was intensive and hard. It was an attempt, in the rush and confusion of war, to produce officers in the minimum period of time. The purpose was to turn out the largest possible number of platoon leaders and a limited number of company commanders and officers of field grade. The same general plan was carried out at the training camps for officers in the quartermaster corps, medical corps and other staff corps. The courses turned out many tens of thousands of officers with elementary training supplemented later by work with the divisional organisations to which they were assigned.

Congress, recognizing the value of the training camps established prior to and during the World War, provided in its 1920 revision of the National Defence Act for their retention. In 1921 ten Citizens' Military Training camps were held and 10,000 men were given training. Since 1921 camps held annually have been increasing in numbers and in attendance; in 1928 approximately 50 camps were conducted in the United States and Porto Rico at which about 35,000 men were enrolled The type of training given in the post-war camps differs materially, however, from that given in previous camps The present camps are attended by younger men and the courses conducted emphasize equally citizenship training, military training and physical development. While the minimum age for attendance is 17 years and the maximum 31 years, the majority attending are under 21 years of age The Government bears all the expenses of attendance and instruction. The complete course extends over a period of four years, occupying one month each year Graduation from the complete course is a material step towards a commission in the Officers' Reserve Corps.

TRAINING CORPS, OFFICERS'. The creation of the Officers' Training Corps (Junior and Senior divisions) dates from 1908. Its aim was twofold: (1) to provide students at schools and universities with a standardized measure of elementary military training to enable them eventually to become special reserve or territorial officers, (2) to create a potential reserve of junior officers to meet a national emergency.

The Junior Division is composed of boys of 13 years of age and upwards in public secondary schools and is officered by the masters in those schools. The former incur no military obligation when they leave school, but the latter as they are commissioned officers of the Territorial Army are under the same obligations and enjoy the same privileges as other officers of that Army. Though equipment is supplied from army funds and training is supervised by the War Office, each contingent is definitely under the control of the school authorities by whom the training is highly valued as a means of character building. The cadets are prepared for the written and practical examination for "Certificate A," which qualifies for a commission in the territorial army or special reserve. In Nov. 1928 out of 3,450 candidates, 2,803 obtained the certificate.

In 1909, the Junior Division comprised 123 contingents containing 311 officers and 13,814 cadets. By 1928 there were 171 contingents with 618 officers and 34,805 cadets. (Two new ones just recognized are not included)

Grants are paid by the War Office in respect of efficient cadets and for holders of "Certificate A" taking commissions in the Territorial Army, but parents bear 50% to 90% of the total expenses. There are 173 contingents of the Junior Division and 176 contingents on the waiting list, belonging largely to the schools which have Cadet Corps The latter are under the control of the County Territorial Associations and, except for a very small grant per head, have to find the whole cost of the training and equipment of both the cadets and the officers.

The Senior Division contains 20 university contingents consisting of 177 officers and 4,469 cadets. The cadets are prepared for "Certificate A" and for "Certificate B," the latter certificate carrying certain privileges in connection with candidates for commissions in the Regular and Territorial armies. In May 1928 111 candidates entered for "Certificate B" and 105 were successful. The contingents include cavalry, artillery, medical, surveying, sound ranging, engineers, signal, veterinary, infantry, air units, etc., whereas the Junior contingents are, with the exception of 3 engineering units, all infantry.

To qualify for grant a cadet in the Senior Division must do the requisite number of drills and the musketry course, and attend camp for 10 days. Cadets are eligible by nomination for commissions in the Regular Army, Territorial Force, Reserve of Officers and for regular and short service commissions in the Royal Air Force They thus furnish a valuable source of supply of officers for the Territorial Army—which needs 1,600 new officers each year—for the Special Reserve, and for the Regular Army, whose needs are not fully met by the Royal Military College and the Royal Military Academy During the World War no less than 35,000 officers were supplied by the Officers' Training Corps. (F. R H.-J.)

TRAJAN (Marcus Ulpius Traianus) (A D. 53–117), Roman emperor, was born at Italica, in Spain, on Sept 18, 53. The family to which he belonged was probably Italian by blood. His father began as a common legionary soldier. and fought his way up to the consulship and the governorship of Asia The younger Trajan was a soldier born and bred

For ten years he was a military tribune, serving all over the empire; then he held important posts in Syria and Spain. By 89 he had a considerable military reputation In that year he was ordered from Further Spain to the Rhine to deal with the revolt of Saturninus. He covered the distance very quickly, but the rebellion had been crushed before his arrival He was consul in 91. Nerva on his accession made him consular legate of Upper Germany, and on the advice of L Licinius Sura adopted him as his son and successor on Oct 27, 97. The senate confirmed the choice and acknowledged him as the successor Trajan at the time was in Germany Shortly afterwards, at Cologne, he received news of the emperor's death (Jan 25, 98). Trajan's authority was at once acknowledged all over the empire He gave the senate an assurance like that given by Nerva, that he would neither kill nor degrade any senator, and ordered the foundation of a temple and cult in honour of his adoptive father, but he did not come to Rome till he had inspected the Rhine-Danube frontier. The praetorians, who had been a menace to Nerva, were quickly overawed, and he proceeded to make his long-awaited entry into Rome Here he at once made himself popular with both senate and people Soon afterwards he left for his first Dacian campaign It would appear that Trajan himself wrote an account of this war, but only one sentence has survived We are left with the evidence of Trajan's column and the monuments at Adamklissi.

This much may be said Roman prestige and security were threatened by the terms of peace exacted by Decebalus from Domitian Trajan took the initiative in 101; his advance, more or less unopposed at first, ended in an indecisive battle at Tapae, at the entrance to the Iron Gate pass Trajan retired to winter on the Danube. The winter seems to have been disturbed by a raid by Dacians and Roxolani into Moesia The next spring Trajan invaded Dacia again His advance ended in an attack on a stronghold (identified as Muncel Cetate), and a complete victory near Koztesd. Decebalus surrendered, a garrison was left in Sarmizegetusa, and Trajan withdrew In 105 Decebalus revolted, and again (probably) invaded Moesia Trajan started at once from Ancona, and seems to have spent the first season in Moesia, making his way to his bridge at Pontes and wintering there. The next year (106), after prolonged and desperate fighting, Sarmizegetusa was taken, and Decebalus committed suicide. Dacia was annexed, the capital became a colony, *Ulpia Traiana,* and the new province was gradually Romanised in the usual way.

There followed seven years of peace, broken at last by war with Parthia The *casus belli* was the appointment by the new king of Parthia, Chosroes, of a nephew to the throne of Armenia without the customary application to Rome, but there must have been something behind that, for Chosroes' instant apology failed to placate Trajan There were three campaigns. The first (114)

resulted in the annexation of Armenia almost without opposition.

The next year, still without much fighting, Trajan occupied Mesopotamia up to the Tigris. There he halted, and went to Antioch for the winter. In 116 he first marched through Edessa and Nisibis, forced the passage of the Tigris without difficulty, and annexed Adiabene, which became the province of Assyria. Then he turned down the Tigris to Ctesiphon Chosroes fled, and Trajan went on down stream to the shores of the Persian gulf, where he looked over the waters to India, and said sadly, "If only I were younger." The captured territory became the province of Parthia

Then, on the way back, the trouble started Before the end of the year a serious rising in the north had to be crushed, and the Parthians were threatening a counter-attack. Trajan decided to abandon lower Mesopotamia, installed the young prince Parthamaspates as king in Ctesiphon, and withdrew, not without trouble on the way Meanwhile the Jews all over the East had risen and massacred everyone they could find, Greeks and Romans alike Trajan, alarmed by this and other signs of trouble all over the empire, set out for Rome He died on the way, at Selinus in Cilicia, on Aug 8, 117 His reign closes ominously; while he had been in the East trouble had started in Africa, Egypt, Libya, Palestine, Sarmatia, Britain He was deified, of course, and his triumph was celebrated after his death Trajan's reign takes one more long step towards complete despotism, which we shall see when we consider the provinces For Italy Trajan did much His new forum was the glory of Rome, there are columns and triumphal arches to commemorate his victories, he reclaimed the Campagna, built new harbours at Ostia, Centumcellae and Ancona, built roads and aqueducts, and tried to arrest the decline of Italy in agriculture and man-power, by extending the *alimenta* system of Nerva, forbidding emigration, encouraging settlements on the imperial lands, making senators invest in real estate in Italy, and so on.

His provincial administration is a little less easy to summarise In intention it was excellent, but his long absence in the East led to difficulties Numerous prosecutions for extortion show the extent of the evil and the emperor's efforts to stop it. This reign sees also a new phenomenon, the breakdown of local government on the financial side Various municipalities have to receive curators, and the province of Bithynia and the "free cities" of Achaea had their financial administration taken over by imperial *correctores* Pliny was sent to Bithynia, and his letters to Trajan and the replies are preserved In the enormous mass of detail referred to the emperor we can see foreshadowed the complete centralisation that was to come under Diocletian Mention must also be made of the view (Rostovtzeff, see *inf*) that Trajan's wars were completely disastrous to the empire, overstraining its man-power and economic strength irrevocably

Bibliography.—The records of the reign are inadequate. The best are Dio Cassius, lxviii, Pliny, *Panegyric* and *Letters.* Of modern works, there are monographs by H Francke (Güstrow, 1837), De la Berge (Paris, 1877), Dierauer in M Budinger, *Untersuchungen zur romischen Kaisergeschichte* (Leipzig, 1868), *see* also L Cantarelli, *Le Fonti per la Storia dell' Imperatore Trajano* (1895), M I Rostovtzeff, *Social and Economic History of the Roman Empire* (1926), B W. Henderson, *Five Roman Emperors* (1927); for the chronology, Mommsen in *Hermes*, III, p. 30, and for Trajan's Pillar, C Cichorius, *Die Reliefs der Trajansaule* (4 vols 1896–1900); G. A. T Davies in *Jour. Rom. Stud.* VII. (1917) and X. (1920).

TRALEE, a seaport and county town of co. Kerry, Ireland, on the Ballymullen or Leigh river, and on the Great Southern railway Pop (1926) 10,536 Tralee, anciently Traleigh, the "strand of the Leigh," owes its origin to the foundation in 1213 of a Dominican monastery It was incorporated by James I A ship canal, permitting the passage of ships of 200 tons' burden, connects it with Tralee bay Large vessels discharge at Fenit, 8 m. westward, where there is a pier connected with Tralee by rail Coal, iron and timber are imported, and there is a considerable export of grain. There is a large trade in butter Railways serve the neighbouring seaside watering-places of Ballybunnion and Castlegregory. Ardfert cathedral, 4 m N W of Tralee and now united to the see of Limerick, was founded by St Brendan and had once a university. A neighbouring round tower fell in 1870.

TRALLES (mod. *Güzel Hissar*), an ancient town of Caria, Asia Minor, situated on the Eudon, a tributary of the Maeander. It was reputed an Argive and Thracian colony, and was long under Persian rule, of which we hear in the history of Dercyllidas' raid from Ephesus in 397 B.C Fortified and increased by the Seleucids and Pergamenians, who renamed it successively Seleucia and Antiochia, it passed to Rome in 133 Rebuilt by Andronicus II. about 1280, it was superseded a few years later, after the Seljuk conquest, by a new town, founded by the amir Aidin in a lower situation. (*See* Aidin.)

TRAMWAY. A track or line of rails laid down in the public roads or streets (hence the United States equivalent "street railway") along which wheeled vehicles are run for the conveyance of passengers and, occasionally, of goods; also a light roughly-laid railway used in coal mining and for carrying out public works.

Construction.—The earliest form of construction consisted of primitive lines or trams of wood or flat stones Later, in 1676, the longitudinal timbers forming the rails were laid on transverse logs and provided with a stout capping of beech or sycamore to facilitate easy renewal of worn sections without undue disturbance of the understructure In 1767 iron plates were substituted for the wood capping; and early in the 19th century iron rails were used

The first tramway or street railway intended for public passenger traffic was the New York-Harlem line opened in 1832 The rails had a deep wide groove which proved so dangerous to the ordinary light narrow-tyred vehicles of the period that they had soon to be removed Twenty years later Loubat, a French engineer, devised and used a wrought iron rail with a narrower groove and with a clearance suitable for wheel flanges In 1855–6 Charles L Light, an English engineer, designed a rail with a groove limited to $\frac{7}{8}$ in in depth and carried up to the surface with a slight slope for a tramway in Boston, U S A No form of grooved rail, however, seemed to suit the conditions of local traffic in the United States, and an entirely different kind of rail was introduced and used in the construction of a tramway in Philadelphia. This consisted of a flat rail 5 in wide, with a step at one side raised $\frac{7}{8}$ in above the surface It was made of wrought iron and weighed 50 lb per yard

Loubat in 1855 laid down a tramway in Paris—the first of its kind in Europe It was a replica, in most respects, of his New York form of construction. The rail was 3 in wide on the surface and had a groove $1\frac{1}{4}$ in wide and $\frac{7}{8}$ in deep, with a tread $1\frac{1}{8}$ in wide It was of a semi-hexagonal section at the lower side, to rest upon a timber sleeper which was chamfered to receive it, and upon which it was spiked diagonally through the sides A fishplate of iron, 6 in long and $\frac{3}{8}$ in thick, was laid under each joint The rail weighed 19 kg per metre or 38 lb per yard The tramways first constructed by G F Train in England in 1860–3 had a step rail of the Philadelphia pattern This rail was manufactured of wrought iron and weighed 50 lb per yard It was 6 in. wide and had a step $\frac{3}{4}$ in above the sole The rails were spiked to longitudinal timbers laid on transverse sleepers English people, unlike the American, would not however tolerate the danger and obstruction caused by the step rail, and the tramways in London had to be removed after a brief period of working, while those initiated by Train at Birkenhead and in North Staffordshire were preserved by the timely substitution of a flat grooved rail.

The adaptation of the steam locomotive for street tramway purposes necessitated tracks of greater strength and rigidity than were sufficient for horse traction The older methods of supporting the rails were inadequate for stability, and many attempts were made to overcome the difficulty Finally recourse was had to the girder rail which soon proved its superiority to the built-up rail, and it eventually became predominant in tramway construction. A form of girder rail was patented in 1860 by Charles Burn; reinvented and patented in 1877 by Achille Legrand of Paris; and with modifications again patented in 1878 by J. Gowans, who succeeded in establishing its greater merits after the lapse of 20 years from the time of its original inception.

The method of construction of modern street tramways follows the same general principle in all countries; variations depending upon local conditions which govern the depth of the con-

crete foundations, weight and composition of the rail, and the class of paving. In cities the foundation consists of six or more inches of concrete The rails weigh about 110 lb. per lineal yard, and are of 45 ft or 60 ft. in length, according to requirements. Heavy fishplates are used for the joints of the rails or the rail ends are electrically welded together. Steel tie-bars are interposed at short intervals and, where electric traction is the motive power, the rails are bonded together by copper rods to provide a continuous path for the return current (and to prevent leakage and consequent possible electrolysis of contiguous pipes). The surface of the rail is laid flush with the paving which may be of wood blocks or granite or basalt setts, grouted with cement

FORMS OF TRAMWAY TRACTION

Animal.—The original street tramways were worked solely by animal traction, the cars being drawn by one to four animals, according to the contour of the routes and traffic necessities An average speed of six to seven miles per hour was customary, and the cost of horse maintenance and renewals averaged 40% to 45% of the total working expenses

Steam.—The need for higher speeds, quicker acceleration and larger and more comfortable cars than were practicable with animal traction, led to the evolution of a type of steam locomotive suitable for street tramway purposes Some extraordinary designs were produced, not only for the engines themselves but for their position in the car One inventor placed his engine at the front; another in the centre, and a third provided an engine at each end of the car Between 1871 and 1883 many experiments on other forms of locomotives were carried out, including fireless locomotives in which well-insulated cylinders (filled with water which was heated from a stationary boiler at the end of each journey) together with the machinery were placed under the floor of the car Ammoniacal gas and compressed air also found devotees but after many trials an enclosed steam engine coupled to the car became standardized, and rendered on the whole quite efficient service until displaced by electric traction. It was employed on most of the tramways in the manufacturing areas of England Locomotive power and repairs and renewals of engines approximated 42% of the total working costs.

Gas.—The development of the gas engine for industrial purposes seemed to offer possibilities for its introduction for street traction Accordingly trials were made, principally in Germany, of small gas engines placed on the outside platform of the car, with the gas receivers accommodated under the floor, the gas being taken from the town mains and then put through a compressing engine before being admitted into the cylinders

Cable.—The principle of cable haulage was first applied to street tramways in 1873 in San Francisco by Andrew S Holliday. It was introduced in England in 1884 on Highgate Hill, London, and installations followed subsequently at Brixton Hill and at Edinburgh, Birmingham, and Matlock. All these have since been discontinued, but there is still a small cable undertaking in operation at Douglas, Isle of Man In cable systems haulage is effected by an endless wire rope continuously moving in one direction, supported on pulleys within a slotted conduit laid below the surface of the street or roadway, or between the rails of a surface or elevated railway The rope is driven by means of a steam engine or motor situated at a convenient place near the line, the motion of the cable being intermittently communicated to the cars for starting and stopping by means of a gripper attached to the car. The tube is formed of concrete with cast iron yokes spaced at intervals of 4 ft to support the slot beams. The slot is usually ¾ in wide and the conduit about 19 in. deep x 9 in. wide

Electric.—The history of the electric tramway is covered under ELECTRIC TRACTION There also will be found a description of the engineering accomplishments that resulted in its superseding all other forms of tramways.

Much controversy used to occur as to whether the overhead or conduit system should be installed. Engineers and financiers advocated the former on grounds of economy of cost of construction as well as of operation. But the general public was loth to sacrifice the amenities of the streets by permitting the erection of poles and overhead wires, and demanded a less obtrusive form of construction In the end the economy and merits of the overhead system prevailed, the exceptions being confined to capital cities such as London, Washington, New York, Paris, Berlin, Brussels and a few other places where financial considerations were subordinated to the aesthetic views In this system the trolley wires are usually hung about 21 ft above the rails The poles are placed not more than 40 yds apart

Surface Contact.—The high cost of conduit construction and the objectionable character of the overhead wires respectively were incentives to the invention of an alternative method of construction Attention was given by engineering specialists to the surface contact systems and a number of designs were patented Among those put into practical use in England were the Lorain system at Wolverhampton, the Dolter system at Torquay, Hastings, and Mexborough, and the G B system at Lincoln On all these systems current is supplied from iron studs laid in the roadway between the rails of the track to a skate carried on the car. The studs were placed every 10 ft to 15 ft, and contained a movable switch or contact which was operated by a magnet carried under the car.

Storage Batteries.—In theory storage batteries afford a simple and convenient form of electric traction, but extended trials have failed to justify their permanent adoption Cars operated by batteries prove costly to work and maintain

TRAMWAY CARS

The car operated on the pioneer lines in New York in 1832 was fashioned after the "voiture omnibus" of Paris, a vehicle designed by an English coachbuilder, George Shillibeer The body had three compartments and was supported on leather springs The four iron wheels, all of the same diameter and flanged, were placed centrally A dickey or elevated seat accommodated the driver and two passengers, and the foot-brake operated on one pair of wheels only The standard horse-car of 1880–90 had seats for 18 inside passengers and 18 outside, the upper deck being approached by a straight staircase

Modern car bodies are mounted either on a single four-wheeled truck with a fixed or rigid base 6 ft to 8 ft long, according to the sharpness of the curves to be negotiated, or on bogies or swivelling trucks The truck may be described as a carriage or frame supported on the axleboxes, and supporting by another set of springs the car body Of bogie trucks two types are used. one the "maximum traction" truck, having a pair of wheels of standard size—about 30 in—with another pair of smaller or "pony" wheels, and the other having four wheels of equal diameter. The single and maximum traction trucks are fitted with two motors, while the equal-wheeled bogies may have four motors. The trolley standard placed on the roof or upper deck of the car carries an arm which through a revolving wheel collects current from the overhead wires; instead of a wheel a frame shaped like a bow is sometimes used for the same purpose Controllers on the platform enable the motorman to stop, start and regulate the speed of the car by means of a handle on the upper surface of the controller frame which has notched divisions The brake equipment comprises a powerful hand brake with a foot ratchet, operating shoes on each side of the wheels, and a magnetic brake forming part of the controller equipment

While the various forms of trucks are common both to British and American practice, car body construction differs in many respects The single-deck car is in general use outside Great Britain where, although many single-deck cars are worked, the greater number are of the double-deck type

In addition to the types here mentioned other designs are to be found. Single-deck open cars of the "toast-rack" type with transverse seats are employed on many holiday lines. and the Californian type of car body, with the control part closed in and one or two double-sided transverse seats at each end, is sometimes used on routes where low bridges preclude the use of double-deck cars The earning value of this type is, however, small when weather conditions are unfavourable.

GREAT BRITAIN

Legislation.—Statutory sanction is necessary for the construction and working of a tramway on public streets or highways. The earlier tramways in England were constructed by private enterprise under powers conferred by special acts of parliament In 1870 parliament passed a general act "to facilitate the construction and to regulate the working of tramways" in Great Britain.

This 1870 Act of Parliament which is still in force, confers upon local authorities powers to construct and alternatively the optional right to purchase, but not to work, a tramway undertaking established by private enterprise upon the expiration of 21 years, and at every subsequent period of 7 years, at the "then value" of the tramway, land, buildings, materials and plant suitable to and used for the purposes of the undertaking, exclusive of any allowance for past or future profits or any compensation for compulsory sale or other consideration whatever In the meantime the undertakers are under the specific obligation to repair and maintain at their own expense the roadway between the rails and 18 in on either side thereof, and are subject to numerous other onerous conditions relating to the method of construction and working non-interference with Post Office, telephone and telegraph wires, gas and water pipes, electric cables, the services of carriages to be run for ordinary and work-people's traffic; and the maximum fares to be charged, including reduced fares to workmen, children, etc. The practical effect of the legislation was to constitute the local and road authorities sole arbiters of the tramway situation in the British isles, and promoters or lessees were frequently under compulsion to accept not only the statutory obligations of the act, but also burdens in regard to expensive street widenings and improvements, and otherwise, which were imposed upon them by local authorities. Promoters of new undertakings were deterred and in course of time lessees were difficult to find, in these circumstances some local authorities sought parliamentary powers to work the tramways in their districts After about 1896 parliament permitted any local authorities that so desired to work tramways as well as own them

The general tendency for British tramways to partake of a local, even parochial, character was thus accentuated Within even small but populous areas having several local authorities, horse, steam, and cable tramways were worked as segregated undertakings under separate management Moreover, there was no uniformity of gauge in the country, gauges of 4 ft 8½ in, 4 ft. and 3 ft. 6 in were adopted without regard to the needs of the travelling public for interconnecting services between towns The striking example of the adjacent cities of Leeds and Bradford, with gauges of 4 ft 8½ in. and 4 ft respectively, still exists

The advent of electric traction in the nineties opened up new opportunities in Britain. With its dense industrial population in a small area, no country was at that time better suited or riper for electric traction on street tramways on a large scale But this important industrial development suggested and, to some extent, initiated by private enterprise, was to a large extent frustrated by the territorial spirit of local government However, the need for linking up urban tramway systems, the development of intermediate townships, and the consequent better distribution of population and industries in a manner similar to that of large and successful street railway systems in the United States, was strongly urged on the Government by Stephen Sellon, a prominent parliamentary engineer, and others, with the result that the Light Railways Act of 1896, avoiding many of the imperfections of the Tramways Act of 1870, was passed The power given to local authorities to veto the promotion of a light railway or tramway disappeared, and the act did not give any option to the local authorities to purchase the undertaking Section 7 of the act, however, provided that the commissioners who were appointed to administer the act were to satisfy themselves that all reasonable steps had been taken for consulting the local and road authorities affected, and the owners and occupiers of the land proposed to be taken. The commissioners seemed to interpret the Light Railways Act in the terms of the old Tramways Act (which is still in force) rather than in the spirit of the departure from it implied by the new act, and included in most of the orders they made an option to the local authorities to purchase the light railway undertaking within their area at the end of a period of 30 years and at subsequent intervals of 10 years, the terms of purchase generally to be the fair market value of the undertaking as a going concern The more equitable provisions of the 1896 act removed some of the conditions in the Act of 1870 which had deterred capitalists, and the British Electric Traction Company, Ltd, and other companies, were formed with the object of providing and operating urban and interurban systems of tramways and light railways.

COMMERCIAL RESULTS

Tramways as public utility undertakings have undergone more changes than any other service of public utility, *e g*, water, gas, electricity supply, or steam railways For more than 30 years improvements in rail and track design followed one upon another, each accompanied by some loss of capital and dislocation of working routine. Rolling stock, too, was remodelled, and many alternative methods of traction were tried and improved or superseded The greatest change of all—the adoption of electric traction—involved the writing off or replacement of many millions of capital in the abandonment of existing horse and steam plant equipments, as well as in the provision of central generating plant, reconstruction of track, and erection of overhead electric lines

The following table (see *Garcke's Manual,* 1906, vol x) illustrates the relative values of electric, steam, and horse operation in Great Britain —

	Horse period 1879	Steam period 1898	Early electric period 1904-5
Length of route:			
Mileage open	321	1,064	2,117
Total number of passengers carried	150,881,515	858,485,542	2,068,913,226
Capital expenditure per mile of single track open			
Lines and works	£7,840	£7,770	£11,799
All items .	£9,877	£10,469	£15,599
Percentage of net receipts to total capital outlay	3·97	6 38	6 36
Percentage of working costs to gross receipts	84	77	66
Passengers carried per mile of route open .	469,641	806,703	977,386
do. per car mile	7 77	9 48	9·10
Average fare per passenger .	1 84d.	1 23d.	1·10d.

The benefits arising from the adoption of electric traction have inured more to the advantage of the travelling public than to the promoters and owners of the undertakings To some extent the comparatively small return of 6·36% on the capital outlay was owing to the heavy cost of construction, but to a larger extent it was in consequence of the policy of reducing the fares to a non-profit standard of municipal service. In the matter of fares British and American practice has always differed materially British fares are usually based on stages or traffic points The fares are charged at a given rate per mile—pre-war 1 to 1½ miles for a penny; post-war 1 to 1½ miles for 1½d—with a reduction for longer distances; thus producing differential fares according to distances travelled.

The earlier estimates of the cost of construction and working of electric tramways in Great Britain were based largely on the experience of the American and European undertakings then in operation. Some of the pioneer lines were built and worked within the estimates But as time went on the original estimates were largely exceeded. The overall cost of £9,500 per mile rose to £12,500 per mile, due to superior track construction, more elaborate overhead equipment, use of larger cars, street widenings, and higher cost of road paving imposed upon tramway undertakings The operating costs instead of being 5·30d per car mile, began to average over 6½d. per car mile, by reason of increased rates of wages and of greater wear and tear of track and equipment than was contemplated.

Subjoined are financial and statistical data relating to electric tramways and light railways in Great Britain in 1913–14 and 1926–27, taken from official sources.—

	Municipalities		Companies	
	1913–4	1927–8	1913	1927
Number of undertakings	170	167	94	66
Miles of lines open				
Total route length	1,708	1,850	731	664
Equiv single track	3,047	3,240	1,092	1,052
Capital expenditure	£54,298,188	£84,318,151	£22,371,533	£19,601,626
Gross receipts	£11,396,710	£23,860,707	£3,763,766	£3,890,737
Working expenses	£7,436,884	£18,663,222	£2,342,679	£3,279,925
Net profit	£3,959,826	78 2%	£1,421,087	84 3%

Note A number of undertakings belonging to companies were acquired by local authorities between the periods covered by these statistics

TRAMWAYS AND OTHER FORMS OF TRANSPORT

Since the advent of electric tramways—and especially during the past two decades—other forms of road transport, namely, trackless trolley buses, petrol (gasolene) motor omnibuses, and light railways, also the electrification of suburban railways, have been developed to provide increased travelling facilities for the ever-growing requirements of the public In the absence of any comprehensive scheme for the co-ordination of these different forms of services there has been much overlapping and wasteful competition between them, and reference is made below to proposed legislation with the object of co-ordination of the various services Every form of transport possesses special merits for certain conditions and characteristics of traffic

In the case of *tramways*, these were originally established to provide a better track than that offered by the then inadequate or bad state of the roads Legislation authorizing the construction of tramways gave their owners a monopoly in the form of the exclusive right to operate vehicles with flanged wheels over the lines For these rights many onerous obligations were imposed, indicating that electric tramways are expensive to establish and to operate, because they have been saddled with costs and obligations by obsolete legislation passed before the advent of the electric tramway, but in spite of this the operating costs per seat mile are less than those for any other road passenger transport

Light railways are very similar to tramways The procedure in obtaining powers to establish and operate them is different, and the terms on which they can be acquired by the local authorities of the districts served may in some cases be more favourable to the promoters than is the case with tramways They are, like railways, chargeable with only one-fourth of the district rates; but for all practical purposes where they have been constructed along roads as a means of passenger transport, they fall into the same category as tramways In passing the Light Railways Act 1896, parliament clearly indicated tramway lines constructed under this act being built with a cheap form of construction with rails laid on sleepers like railways, and used for urban and interurban work, connecting up hamlets and villages, and to encourage general agricultural, fishing and freer intercourse between neighbouring small towns

Trackless trolley buses were designed to serve specific routes with road transport facilities, and are suitable for dealing with traffic features similar to those which modern tramways are designed to provide, though in less densely populated districts They have the advantage over tramways of costing less to establish and run, and are more flexible in operation inasmuch as they are free to deviate from a fixed path. They cannot, however, be reversed at the termini of routes with the same ease as tramcars. While such services have not been developed much compared with other forms of road transport, they have been established by several municipalities and companies in this country and on the Continent to deal with moderately dense traffic Their sphere of usefulness is in cases where there is a moderate flow of traffic along a specific route having a good road surface Like tramways and light railways they are very suitable for short-distance traffic For the year 1926–27 nineteen local authorities and one company operated trackless trolley undertakings in Great Britain, while twenty-one local authorities did not exercise their statutory powers The following are some particulars of the operating results abstracted from the return issued by the Ministry of Transport —

Miles of route operated	84 13
Capital expenditure	£714,277
Total income	£286,391
Total working expenses	£249,955
Net revenue	£36,436
Car miles run	5,092,956
Passengers carried	50,382,193

Suburban railways also serve local traffic requirements in a very efficient manner, although the class of traffic for which they are pre-eminently designed is somewhat different from that particular kind of local traffic which forms so large a proportion of that served by tramways, light railways and trackless trolley buses The three latter forms of road transport are designed primarily for frequent stops at short intervals—a continual picking up and setting down of passengers along their routes—whereas the passenger traffic on suburban railways consists chiefly of large numbers of passengers conveyed from the centre of one locality to another, with comparatively short journeys to and from the railway stations

Omnibuses—The comparatively rapid development of omnibus services is perhaps the outstanding feature of modern land transport This development is due primarily to (*a*) the provision of good roads at the cost of other industries and the community at large; (*b*) the skill of the automobile engineer in producing so efficient a machine, (*c*) the improvements made in the manufacture of pneumatic tyres, (*d*) the comparatively low cost of establishing and operating an omnibus service, and (*e*) the fact that unlike other forms of transport referred to, parliamentary powers are unnecessary to establish a service except in the case of omnibuses owned by municipalities or statutory companies Motor omnibuses (single- and double-deck types) as at present evolved are now being used to cater for road passenger traffic of practically all classes The single-deck types are used chiefly for urban and interurban services where the density of traffic is not great, and for touring work, and many regular high-speed services for long distances (50 to about 100 miles) have been established between large towns They are also used in districts where the height of bridges precludes the use of the double-deck type Generally speaking the double-deck types are used for town services where the traffic density calls for a vehicle with larger seating capacity than can be given by a single-deck vehicle This is conspicuously so in London where no tramways are laid in the large central area which comprises the chief commercial and shopping districts, the chief amusements, and some important residential districts within the metropolis On this account the London road transport services are quite special The economic competitive aspect of omnibuses compared with other forms of road transport is to some extent influenced by the limitations as to dimensions and weights of vehicles as imposed by the Heavy Motor Car (Amendment) Order, 1927

Comparisons of Systems.—Having briefly indicated the special features of each form of traction referred to, it is not difficult to visualize the character of the traffic which they are especially suited to provide, and generally speaking there is no very great difference of opinion among transport experts on this important question But experience has shown that in cases where omnibuses are permitted to run and ply for hire indiscriminately over tramways, the tramway revenue can be so depleted as to reduce the undertakings to insolvency, although the motor omnibuses themselves would not be the most suitable form of transport for dealing with the traffic, and it is on this point that confusion of thought among non-transport experts exists A motor

omnibus, being a self-contained vehicle, is a comparatively inexpensive vehicle to provide and operate, and is admirably suitable for dealing with many kinds of traffic characteristics It is extremely mobile and can be operated in different districts at different parts of the day, in this manner depleting the tramway revenues just when it was earning a profit.

Apart from the merits of the two forms of traction for dense traffic conditions, the question of the capacity of the roads in large towns is a very important factor to be studied. Another important question—national in its bearing—is the fact that practically the whole of the motor spirit used to propel motor omnibuses is imported It is difficult to realize what the position of road transport in this country would be if there were no electric services and omnibus fuel supplies were for any reason cut off for a prolonged period The French Government is so concerned at the undesirability of having to depend on imported fuel for transport purposes that they have given much encouragement to the discovery and use of petrol substitutes On the other hand, the omnibus has the advantage over tramcars in that it can draw up to the side of the road for the convenience of picking up and setting down its passengers Much confusion of thought on the merits of tramways has been created owing to several tramway systems having been discontinued and superseded by omnibuses or trackless trolley buses These changes were made mainly because the tramways were established to deal with traffic which in these cases never was and probably never would have been sufficiently dense to justify their establishment and continuance Nevertheless these matters do not detract from the value of tramways for dealing with dense city and suburban traffic, where the requirements call for permanent way with double track and large-capacity tramcars operated at frequent intervals at high speeds Many of the managers of large road passenger transport undertakings, some of whom are responsible for both tramways and omnibuses, have recently expressed the view that on their true merits tramways for dealing with dense city traffic have nothing to fear from omnibuses Some figures recently published in connection with the Manchester Corporation tramways and omnibus services give the working costs per seat mile as being 0·21d. for the tramways and 0·46d for the omnibuses In London the cost of operating a double-deck omnibus averages 0·263d per seat mile, and 0·190d for tramways It is obvious that if tramways were relieved of their onerous obligations referred to above, the cost of operation per seat mile would be still more favourable to them

Summary.—Much evidence has recently been given by officials responsible for large combined tramway and omnibus undertakings, to indicate that tramways form an indispensable part of road transport required to cope with the ever-increasing traffic in large cities where, in most cases, by far the greatest proportion of the whole passenger traffic is still carried by tramways. The London and Home Counties advisory committee, which was set up under the London Traffic Act, 1924, to bring about co-ordination of transport systems, confirmed this by expressing similar views They "consider that tramways are an essential part of the passenger transport system in the metropolis" Several large municipal tramways are being extended into the suburbs with special track construction along new and modern thoroughfares

Summarizing the above it may be said generally that.—

(1) Tramways are pre-eminently suitable for main city routes where the traffic is dense

(2) Trackless trolley buses are suitable for traffic of moderate density, cross-town work, and feeders to tramways, where the roads are suitable for their use

(3) Motor omnibuses have a wide range of usefulness for dealing with traffic varying from light to heavy. They are more mobile than other forms of public transport vehicles, but create more congestion than tramways and reduce the capacity of the roads, especially at city termini, when used for dealing with heavy traffic They are dependent on imported fuel There are cases where their use to augment tramway services during the heavy peak loads is well worth consideration

(4) Light railways, as developed for road traffic purposes in Great Britain, are similar to tramways Powers authorizing their construction have not been used to a large extent for the express purpose intended by legislation, although the comparatively cheap form of construction (sleeper track) is being used to extend into the suburbs some large city tramway undertakings

(5) Suburban railways are used in large cities for the transportation between localities as contrasted with pick-up traffic along the routes. The services are frequently superimposed on main line railway services.

Even with the best of co-ordination of the various forms of transport, there is bound to be a certain amount of direct or indirect competition between them, and to organize the best scheme for any particular conditions on their merits as transport agencies, calls for high degree of experience and expert transport knowledge The desirability of the co-ordination of the various forms of transport to enable all to function according to their respective merits was appreciated by the Government, and a royal commission was appointed in 1928 to consider the matter. The evidence given before the joint committee of both houses of parliament in connection with the omnibus powers being sought by the railway companies indicates the urgent necessity of legislation to deal with this important question There is a growing feeling that legislation in this connection is vital to the co-ordination of this country's transport services, and to protect and encourage them in such a way as to ensure healthy expansion and improvements in these services on which England depends for its industrial development and welfare (E. Gar.)

UNITED STATES

As far back as 1746 stage coaches were running in New York carrying passengers on Broadway to the Battery, and other lines of this type were in existence even earlier But the street railway business as such cannot be said to have actually begun until the adaptation of the "railway" principle to transportation in city streets. Apparently the earliest record of a "street railway" in America is that of an omnibus car known as the "John Mason," which in the third decade of the 19th century operated in Fourth street, New York This car was drawn by horses and ran on strap rails laid on stone ties During the two succeeding decades there seems to have been very little new development, though the demands of the fast growing communities gave rise to a vast number of omnibus and stage coach lines Twenty years after the advent of the John Mason the Sixth Avenue railroad of New York was built, and between 1850 and 1855 six new rail lines appeared in different parts of the country

Thereafter the new idea developed rapidly, though not without considerable opposition on the part of the more reactionary element, who saw in these noisy and rapidly moving vehicles only detriment to property values and danger to life and limb The superior comfort of the rail carriages as compared to the old-fashioned omnibus jolting over rough cobblestone pavements was soon demonstrated Between 1855 and 1860, 30 street railway lines were built Between 1860 and 1870, 80 new lines appeared By the year 1890 there were 769 street railways in the principal cities of the country

Early Development.—Most of the new lines met with apparent success from the start Operating data and financial reports of these early days are meagre and unreliable, but it is certain that the rapid industrial development of the period assured a growing demand for local transportation. The ease with which franchises were obtained in most cities also gave encouragement to promoters Each line was usually operated as a separate corporation and under a separate franchise. Runs were comparatively short At first each company charged a separate fare, but before many years in most cities agreements permitted interchange from one line to another, usually upon payment of an "exchange" fare slightly above the regular fare Fares were almost invariably fixed at 5 cents for a single ride of any length Fares rose temporarily in most cities, following the Civil War, to 6, 7 and even 8 cents. The 5 cent fare persisted throughout the latter part of the 19th century and up to the World War.

The use of horses for motive power continued until about 1890. A number of cities, notably San Francisco, where very difficult grades were encountered, had cable systems but the heavy installation cost involved stood in the way of any general abandonment of the horse car systems in favour of cables. This factor also worked against the adoption of electricity as a motive power. Early experiments by Edison, Field, and several others

had shown the practicability of a railway with cars operated by electricity, and F. J. Sprague is generally credited with having built and operated the first actual electric street railway in Richmond, Va, in 1888 with about 12 m of track and 40 cars A further serious obstacle to the growth of electric railways was the excessive cost of producing electric power As soon as new developments in power production and transmission largely overcame this difficulty, a new era began in urban transportation

Combination of Lines.—The late '80s and early '90s brought about the gradual combination of the independent lines, through a series of mergers, so that there emerged one single street railway system in nearly every large city. No cable or horse car systems were proposed after 1890, and by 1902 the electric car was in almost universal use in all principal cities The amalgamation of independent lines into a unified system for each community undoubtedly effected substantial economies in operation and made possible a more satisfactory grade of service. Unfortunately, in keeping with financial and political practises of the time, these amalgamations were often accompanied by flagrant abuses. Many managements shaped their policies with little regard for either the public welfare or the permanent economic good of the community or the transit system Such tactics on the part of the so-called "traction magnates" naturally gave rise to a deep-seated feeling of distrust on the part of the riding public Wages and working conditions of the street car employees during these years were probably as poor as those in any industry. The public's distrust of the owners thus came to be shared by the workers, and street car strikes were frequent and violent in all parts of the country.

Regulation.—It was during the early part of the present century that the condition of the street railways sank to the lowest point in their history After long agitation and political controversy, came the public utility commissions, designed to regulate the conduct of public utility enterprises in the interest of the public and with regard to the rights of investors in the properties. For several decades most of the States had had what were known as railway commissions, which came into existence with the advent of the steam railroads These railway commissions, however, were confined practically to the gathering of information and had little or no authority in matters of rates and service New commission laws were passed in 1905 in Washington, Wisconsin and Indiana, which gave the commissions of those States complete jurisdiction over rates and service of all common carriers, with authority to enforce their rulings

To-day every State in the Union has its utility commission State public utility commission laws have in general followed the form of the Interstate Commerce Commission of the United States. The theory of public utility regulation is briefly and generally that a "business affected with a public interest" is one which should be subject to a certain measure of public control. This applies with special force to undertakings which are in the nature of legal or natural monopolies and which, by virtue of certain privileges extended to them by the commonwealth, assume the obligation of rendering service to the public By virtue of the assumption of such obligations the utility is regarded as having the right to be protected from competition and the right to earn a fair return on the value of its property. Much controversy has arisen as to the legal definition of "fair return" and "fair value." Commissions generally have defined fair return to a public utility as that return which would be realized from any other business where the risks and capital investment are the same In actual practice 7% per annum has been generally indicated Fair value has been harder to define. Arguments have been advanced in favour of original cost of plant and improvements, present capitalization, prudent investment, cost of reproduction and present value as a going concern. The U S. Supreme Court has refused to accept any one of these bases for determining fair value and has indicated that commissions may take into consideration any or all of these factors and give to them "such weight as may be just and right in each case." (*See* PUBLIC UTILITY.)

Competition and Rising Costs.—The serious condition in which the street railways found themselves prior to 1915 was greatly aggravated by the unprecedented conditions brought about during the World War Labour and material costs rose steeply while at the same time the street railways began to encounter serious competition in the form of the taxi, motor-bus and private automobile. Some idea of the acuteness of the situation may be had from the fact that in 1919, 7 8 of the mileage and 9 per cent of the securities invested in the street railway industry were involved in receivership, exceeding by a considerable degree any previous year.

At this juncture President Wilson appointed the Federal Electric Railway Commission to study the situation of the electric railways and suggest measures for their relief The commission attributed the cause of the railways' condition to the high cost of labour and materials, early financial mismanagement, and the inadequacy of the existing fare system It recommended, in general terms, a redoubling of the efforts to effect economies in operation and to improve service It recommended also that some relief be given the companies in the way of elimination of special assessments and taxes, pointing out at the same time that strict regulation of independent motor-bus operators should be undertaken to lift the burden of undue competition Little progress was made in the immediate ensuing years. Later however, many of the recommendations made by the commission were put into effect with the result that public, employees and owners have all benefited materially

Private Automobile.—Prior to the advent of the World War the use of private automobiles in the United States had reached very considerable proportions, but the increase in the manufacture and sale of automobiles following the close of the war was phenomenal.

No factor in the entire situation has been more detrimental to the success of the street railways of the past nor more threatening in the future than this ever-increasing tendency of the public to ride in privately operated vehicles Many studies have been made which have purported to trace the future trend of automobile usage to an ultimate point All such prognostications that have been made in the past have proven fallacious in the light of actual experience

Motor-bus.—Gasolene propelled double-deck motor-buses had been in use on certain streets of New York and Chicago for many years, but throughout the remainder of the country they were practically unknown Starting, however, with the rather small beginning which they had during the World War when many of the street railway companies were unable to supply service adequate to the demands of the vast army of factory workers, the use of motor-buses increased with great rapidity in all sections of the country Street railway managements for several years made the mistake of attempting to regulate and legislate the motor-bus out of existence. It could not be done The motor-bus had several points of superiority over the street car which in the public mind sufficiently offset its obvious drawbacks After fighting a losing battle for several years, street railway managements undertook to co-ordinate rather than outlaw the motor-bus The larger street railway companies at the present are realizing that their business is one of public transportation, not limited to one particular form of vehicle, each vehicle eventually fitting into a co-ordinated whole, so as to obtain the most efficient and economic results for the community

As a rule, double-deck buses have been found most practical in thickly settled sections where traffic is heavy, single-deckers are used for suburban and intercity routes Seating capacity is usually from 45 to 70 in the double-deck buses and from 20 to 35 in the single-deck Many companies prohibit the carrying of standing passengers. The rate of fare on city motor-bus routes is almost universally 10 cents The extent to which street railway revenues and development have suffered through the inroads of motor-bus competition is indicated by the fact that the number of motor-buses in use in the United States has increased from 52,925 in 1924 to over 92,325 in 1928; while the number of passengers carried by motor-buses has reached a total of 1,826,-000,000 in 1928 During recent years the figure for street rail-

way passengers has remained practically stationary and the number of cars in use has decreased Further light is thrown on the more recent tendency of the street railway companies to absorb motor-bus operations as a part of the unified transit systems by the fact that whereas in 1922 street railway companies operated only 355 motor-buses, in 1928 the figure had increased to 8,492

Traffic Congestion.—The remarkable increase in the number of automobiles using the highways has created a situation of traffic congestion in the centres of large cities. a real problem for which no adequate practical remedy has yet been devised It constitutes obviously a serious obstacle to regularity of street railway schedules, adds materially to the cost of operation per car mile, and multiplies accident hazards Hundreds of thousands of dollars have been spent by communities, chambers of commerce and street railway managements in making traffic counts and surveys and laying out elaborate plans for remedial measures

Parking of vehicles on city streets is one phase of the situation which has received considerable attention Regulations have been devised to limit the length of time which an automobile may be left standing on the public highway Parking has been prohibited in some sections in nearly every city on one side of the street or on certain portions of some city blocks Limited parking is in some cases permitted at certain hours of the day and forbidden during the hours of greatest congestion These plans have brought a certain amount of relief, but the major problem remains For the most part American city streets were designed with no knowledge or anticipation of the demands which modern conditions would put upon them Present experience indicates beyond question that even the absolute prohibition of the parking of vehicles on highways in the streets would fall short of completely remedying the situation (*See* TRAFFIC and TRAFFIC REGULATION)

Taxicab.—The same reasoning which eventually forced upon street railways the realization that the street car and motor-bus service must be co-ordinated in one system applies with equal force to taxicab transportation The growth and use of the private automobile was accompanied by a similar growth in public patronage of motor-driven cabs This particularly affected the revenues of the street railway companies, because it was the short rider who had always been the most profitable part of the street railway company's business in America where flat rates rather than zone fares were the universal rule, and which was gradually but surely diverted to the taxicabs One or two pioneer street car companies have always handled the taxicab business as an adjunct to their street railway and motor-bus systems In Philadelphia virtually all of the taxicabs are under the control of the street railway management.

Future Development.—From the foregoing one might be inclined to draw a most pessimistic conclusion as to the future of street railway companies in America Yet the situation is not without many hopeful signs Street railway managements generally have accepted a more comprehensive view of their functions and are realizing the need of extending their facilities in the direction of co-ordinated service They are recognizing the need for an ever-improving grade of service to meet the demands of public taste. At the same time they are everywhere inaugurating more enlightened policies with respect to labour; industrial co-operation is the watchword rather than the violent strike of earlier years. The forces of organized labour in the industry have declared, through an agreement with one of the largest management groups, in favour of co-operation as a substitute for militant opposition A much more intelligent policy of public relations has almost universally replaced the former uncondescending attitude which so antagonized the riders At the same time. spurred on by the evident preference of the public for motor-bus and taxicab riding, even at advanced rates, street railway companies and manufacturers are bending every effort toward more comfortable and more inviting vehicles.

The accompanying statement showing gross and net revenues at five-year intervals is evidence of the decided improvement which has taken place in street railway affairs since 1909

Notable advances also have been made in reducing to the minimum costs of operation Particularly the introduction of the so-

Street Railways in United States

	Gross Passenger Revenue	Net Income
1907	$382,132,000	$40,340,000
1912	502,652,000	68,140,000
1917	603,130,000	56,451,000
1922	854,663,000	57,188,000
1927	860,000,000	66,000,000

called "one-man car" has accomplished much in this direction The earliest types of one-man car were extremely small and limited in their application to sparsely settled districts, but developments of safety devices and more thorough training of operators have made possible the use of larger cars operated by one man even in the densest traffic In some of the largest city systems the newer types of one-man car are shown to be safer than the two-man car by statistics of accidents over a considerable period of time

The increased use of city highways in the near future leads one to the inevitable conclusion that, in order to supply anything approaching an acceptable transportation service, the various types of transportation in city centres must be segregated Widening and double-decking of city streets is too costly to be extensively undertaken High speed subways and elevated lines in the larger cities have been a valuable contribution but the cost of their operation and the carrying charges on the enormous investment involved are far beyond what the passenger revenue can be expected to yield Several cities have already adopted the plan of putting some of their surface street railway lines underground when they approach the city centre It is safe to predict that before many years all surface lines will enter congested city centres underground and that all of the short-riding business in the centres of the cities will be taken care of by the free wheel motor-buses and taxicabs

High Speed Lines.—New York, Chicago, Philadelphia and Boston have high speed (either subway or elevated) lines in addition to the surface street car lines Philadelphia and Boston have both made use of the "surface car subway" principle In both of these cities the operation of high speed surface lines and buses is co-ordinated under one management Philadelphia's system is partly city-owned and all operated by private management Boston's transit system, also partly municipally and partly privately owned, is under the control of a board appointed by the State New York city's high speed system, also partly city-owned, is operated by two separate private corporations while her surface lines are divided into several systems, each operating independently All are subject to the control of the city's transit commission Chicago's system of high speed and surface lines, privately owned and operated, is subject to a large measure of city control The city is also planning early construction of municipally owned subways

Already a very substantial portion of the electric railway mileage in the principal American cities is municipally owned or under a large measure of municipal control In addition, nearly all of the larger cities are giving serious consideration to the construction of high speed subway or elevated lines at the city's expense Future extensions of street railway mileage in larger cities will in all probability take the form of high speed trunk lines in subway tubes operating between the congested centres and the more populous suburban districts Elevated structures are not popular owing to their unsightliness, and in congested sections they constitute a serious interference with vehicular traffic The high speed, subway and trunk lines will be supplemented by present surface rail lines in the outlying sections. Additions to present surface mileage will be practically negligible, all lines into newly developed sections being served by motor-buses. Surface railway lines where they enter congested centres will, as already indicated, be placed in underground tubes.

City Ownership and Co-ordination.—While as previously pointed out the situation of the street railway industry is now showing decided improvement, nevertheless the credit of the companies has been so impaired in the last decade and the riding

habit so definitely shifted from public conveyances to private automobiles, that it is extremely doubtful that any street railway company will in the future be able to finance the construction of underground high speed lines There is no indication anywhere that sufficient patronage can be attracted to such lines with a rate of fare which would yield sufficient income to pay operating costs and carrying charges on the investment involved It therefore appears more or less certain that future construction of high speed lines and construction of tubes in which surface cars will be operated will be at the city's expense Municipalities are able to float bond issues at substantially lower interest rates than private utility corporations The construction of such high speed lines materially enhances the value of abutting real estate, which furnishes ample justification for added real estate tax assessments

It may well be that municipal ownership will not stop with the building by the cities of new high speed lines as required, cities may make arrangements by which ownership of the entire transportation system within their borders will pass to the municipality In such eventuality, it appears obvious that such a city-owned system should include not only high speed and surface railway lines but supplementary motor-bus lines and taxicab systems as well, in order to preserve to the municipality as owner the same advantages from co-ordination as have already been shown to accrue to the private companies There is a distinct sentiment throughout the United States against municipally operated transit lines As a matter of fact, in the few isolated communities where municipal operation has been tried in America, the results have not been encouraging In all probability the ultimate development of large city transportation systems will be toward municipal ownership with operation by responsible and experienced private management agencies, to whom will be offered the incentive of contingent remuneration based upon results secured in attraction of patronage and efficiency of operation (*See* TRANSPORT, ELECTRIC TRACTION) (T E M)

TRANCE, a term used very loosely in popular speech to denote any kind of sleeplike state that seems to present obvious differences from normal sleep, in medical and scientific literature the meaning is but little better defined In its original usage the word no doubt implied that the soul of the entranced person was temporarily withdrawn or passed away from the body, in accordance with the belief almost universally held by uncultured peoples in the possibility of such withdrawal But the word is now commonly applied to a variety of sleeplike states without the implication of this theory, ordinary sleep-walking, extreme cases of melancholic lethargy and of anergic stupor, the deeper stages of hypnosis (*see* HYPNOTISM), the state into which many of the mediums of modern spiritualistic séances seem to fall almost at will, all these are commonly spoken of as trance, or trance-like, states. There are no well-marked and characteristic physical symptoms of the trance state, though in many cases the pulse and respiration are slowed, and the reflexes diminished or abolished The common feature which more than any other determines the application of the name seems to be a relative or complete temporary indifference to impressions made on the sense-organs, while yet the entranced person gives evidence in one way or another, either by the expression of his features, his attitudes and movements, his speech, or by subsequent relation of his experiences, that his condition is not one of simple quiescence or arrest of mental life, such as characterizes the state of normal deep sleep and the coma produced by defective cerebral circulation by toxic substances in the blood or by mechanical violence done to the brain.

If we refuse the name trance to ordinary sleep-walking, to normal dreaming, to catalepsy, to the hypnotic state and to stupor, there remain two different states that seem to have equal claims to the name; these may be called the ecstatic trance and the trance of mediumship respectively

The ecstatic trance is usually characterized by an outward appearance of rapt, generally joyful, contemplation The subject seems to lose touch for the time being with the world of things and persons about him, owing to the extreme concentration of his attention upon some image or train of imagery, which in most cases seems to assume an hallucinatory character (*see* HALLUCINATION) In most cases, though not in all, the subject remembers in returning to his normal state the nature of his ecstatic vision or other experience, of which a curiously frequent character is the radiance or sense of brilliant luminosity

In the mediumistic trance the subject generally seems to fall into a profound sleep and to retain, on returning to his normal condition, no memory of any experience during the period of the trance But in spite of the seeming unconsciousness of the subject, his movements, generally of speech or writing, express, either spontaneously or in response to verbal interrogation, intelligence and sometimes even great intellectual and emotional activity In many cases the parts of the body not directly concerned in these expressions remain in a completely lethargic condition, the eyes being closed, the muscles of neck, trunk and limbs relaxed, and the breathing stertorous

Trances of these two types seem to have occurred sporadically (occasionally almost epidemically) amongst almost all peoples in all ages And everywhere popular thought has interpreted them in the same ways In the ecstatic trance the soul is held to have transcended the bounds of space or time, and to have enjoyed a vision of some earthly event distant in space or time, or of some supernatural sphere or being The mediumistic trance, on the other hand, popular thought interprets as due to the withdrawal of the soul from the body and the taking of its place, the taking possession of the body, by some other soul or spirit, for not infrequently the speech or writing produced by the organs of the entranced subject seems to be, or actually claims to be, the expression of a personality quite other than that of the sleeper It is noteworthy that in almost all past ages the possessing spirit has been regarded in the great majority of cases as an evil and non-human spirit, whereas in modern times the possessing spirit has usually been regarded as, and often claims to be, the soul or spirit of some deceased human being Modern science, in accordance with its materialistic and positive tendencies, has rejected these popular interpretations It inclines to see in the ecstatic trance a case of hallucination induced by prolonged and intense occupation with some emotionally exciting idea, the whole mind becoming so concentrated upon some image in which the idea is bodied forth as to bring all other mental functions into abeyance

Science regards the mediumistic trance as a state similar to deep hypnosis, and seeks to explain it by the application of the notion of cerebral or mental dissociation in one or other of its many current forms, this assimilation finds strong support in the many points of resemblance between the deeper stages of hypnosis and the mediumistic trance, and in the fact that the artificially and deliberately induced state may be connected with the spontaneously occurring trance state by a series of states which form an insensible gradation between them A striking feature of the mediumistic trance is the frequent occurrence of "automatic" speech and writing, and this feature especially may be regarded as warranting the application of the theory of mental dissociation for its explanation, for such automatic speech and writing are occasionally produced by a considerable number of apparently healthy persons while in a waking condition which presents little or no other symptom of abnormality When, as in the majority of cases, such speech or writing merely gives fragmentary expression to ideas or facts that have been assimilated by the subject at some earlier date, though perhaps seemingly completely forgotten by him, the theory of mental dissociation affords a plausible and moderately satisfactory explanation of them.

But in recent years a new interest has been given to the study of the mediumistic trance by careful investigations (made, mostly by members of the Society for Psychical Research, with a competence that commands respect) which tend to re-establish the old theory of external possession, just when it seemed to have become merely an anthropological curiosity For this aspect of mediumistic trance the article on *Psychical Research* should be consulted

TRANENT, police burgh of East Lothian, Scotland Pop. (1921), 4,763. It lies 9½ m E. of Edinburgh by road and 1 m. S E of Prestonpans station on the L N E. railway. The town possesses the oldest coal-mining charter (1202–18) in Great Britain, and the mines in the neighbourhood provide the staple industry A fragment of a parish church, said to have been built in the 11th century, still stands The palace of the Setons was demolished towards the close of the 18th century and a modern mansion was erected on its site

In the neighbouring village of Ormiston, in 1885, a granite obelisk was erected in memory of Robert Moffat (1795–1883), a native, the South African missionary and father-in-law of Livingstone At Ormiston Hall, a seat of the marquess of Linlithgow, there is a yew tree, beneath which the reformer George Wishart (1513–1546) used to preach. Hard by is the village of Pencaitland, divided into an eastern and a western portion by the Tyne. The parish church in eastern Pencaitland probably dates from the 13th century. The aisle may belong to the original building, but the rest is of the 16th century, excepting the small belfry of the 17th century The old house of Pencaitland stands in the grounds of Winton Castle, which was erected by the 3rd earl of Winton in 1620 but forfeited by the 5th earl, who was involved in the Jacobite rising of 1715 Five miles south-east of Tranent is the village of Salton (or Saltown), where Gilbert Burnet, afterwards bishop of Salisbury, had his first charge (1665). At his death he bequeathed the parish 20,000 marks for the clothing and educating of poor children He was tutor to Andrew Fletcher, who was born at Salton in 1655 and buried there in 1716. At Fletcher's instigation James Meikle, a neighbouring millwright, went to Holland to learn the construction of the iron-work of barley mills, and the mill which he erected at Salton after his return not only gave Salton barley a strong hold on the market but was also for forty years the only mill of its kind in the British Isles Meikle's son Andrew (1719–1811), inventor of the threshing machine, carried on his trade of millwright at Houston Mill near Dunbar. Andrew Fletcher, also of Salton (1692–1766), nephew of the elder Andrew, became lord justice clerk in 1735 under the style of Lord Milton By his mother's energy the art of weaving and dressing Holland linen was introduced into the village. She travelled in Holland with two skilled mechanics who contrived to learn the secrets of the craft The British Linen Company laid down their first bleachfield at Salton under Lord Milton's patronage. Salton also lays claim to having been the birthplace of the poet William Dunbar.

TRANI, a seaport and episcopal see of Apulia, Italy, on the Adriatic, in the province of Bari, and 26 m by rail W N W of that town, 23 ft above sea-level Pop. (1921), 34,568 The cathedral (dedicated to St Nicholas the Pilgrim, a Greek who died in 1094 and was canonized by Urban II) on an open site near the sea, was consecrated, before its completion, in 1143; it is a basilica with three apses, a large crypt and a lofty tower, the latter erected in 1230–39 by the architect whose name appears on the ambo in the cathedral of Bitonto, Nicolaus Sacerdos It has an arch under it, being supported partly on the side wall of the church, and partly on a massive pillar. The arches of the Romanesque façade are beautifully ornamented; the bronze doors, executed by Barisanus of Trani in 1175, rank among the best of their period in southern Italy. The capitals of the pillars in the crypt are fine examples of the Romanesque. The interior of the cathedral has been barbarously modernized, but the crypt is fine Near the harbour is the Gothic palace of the doges of Venice, which is now used as a seminary S Giacomo and S Francesco also have Romanesque façades and the latter and S. Andrea have domes. The fine castle was begun by Frederick II (1233) and enlarged in the 15th and 16th centuries The Palazzo Caccetta (1458) is a fine Gothic building. Trani produces wine (Moscato di Trani). Trani is the *Turenum* of the itineraries. It first became a flourishing place under the Normans and during the crusades, but attained the acme of its prosperity as a seat of trade with the East under the Angevin princes. Its code of maritime law (the *ordinamenta maris*) is the first of mediaeval codes (1063)

TRANQUEBAR, a town of British India, in the Tanjore district of Madras, on the sea-coast, 18 m. N of Negapatam. Pop. (1921), 11,520 A railway line from Mayavaram was planned in 1924 A Danish factory was opened here as early as 1620. It was taken by the British in 1801, but restored in 1814, and finally purchased, with the other Danish settlements in India, in 1845. In Danish times Tranquebar was a busy port, but it lost its importance when the railway was opened to Negapatam It was the first settlement of Protestant missionaries in India, founded by Ziegenbalg and Plutschau (Lutherans) in 1706; and there is still a Lutheran mission high school and mission press, equipped for printing the native languages

TRANSATLANTIQUE, COMPAGNIE GÉNÉRALE, a maritime steamship line popularly known as "The French Line," was formed as the Compagnie Générale Maritime in 1855 It controlled a fleet of 75 sailing ships, of which many were engaged in the cod-fishing industry off the Newfoundland Banks, and 10 steamers In 1860 the company was awarded the postal contract for a service between Havre and New York The next year the company adopted its present name

The first steamships for its New York service had a gross tonnage of 3,000 tons and a speed of about 8 knots "La Touraine," a turn-screw vessel of 18 knots, built in 1890, held the blue riband of the Atlantic for some time In 1906 the company ran another very fast vessel for her day—"La Province" (21 5 knots on trials), and six years later operated the "France" (24 knots) which still remains one of the fleetest passenger ships More recent additions were the "Paris" (1921) and "Île de France" (1927)

The company maintains, in addition to its New York service, regular passenger and freight services to the West Indies and Spanish Main and to Mexico In the Mediterranean it has an extensive network of lines to North Africa The north and south Pacific are served from Europe by large freighters. In 1928 the fleet of the company consisted of 101 vessels with a total gross register of 570,000 tons The gross tonnage of the Île de France is 44,000 tons (G C. RH)

TRANSBAIKALIA: *see* BURIAT MONGOL A S S R and FAR EASTERN AREA.

TRANS-CANADA HIGHWAY, a highway crossing Canada from ocean to ocean Starting at Halifax, N S, it passes through the Maritime Provinces and along the St. Lawrence river, through Ottawa, to Lake Superior, a distance of about 1,500 miles. It is a graded road from Halifax to Quebec. From Quebec to Ottawa the roadway is paved or hard surfaced; the balance improved, graded or dirt Its central division is not yet completed and the traveller must therefore pass through U S territory from Sault St Marie, to Emerson, south of Winnipeg, Manitoba. The distance from Winnipeg to Vancouver is about 2,000 miles This western section has some semi-hard surfacing but is mostly dirt roadway It passes through Brandon, Man., Regina, Sask., Medicine Hat and Calgary, Alb

TRANSCASPIAN REGION: *see* TURKMEN S S R and KAZAKSTAN A.S S R

TRANSCAUCASIA, a general name given, before the Russian revolution of 1917, to the governments and provinces of Russian Caucasia, excluding the steppe provinces of Kuban and Terek and the steppe government of Stavropol It thus included the governments of Baku, Elisavetpol, Erivan, Kutais and Tiflis; the provinces of Batum, Daghestan and Kars, and the military districts of the Black Sea (Chernomorsk) and Zakataly. It is now applied to the territory of the Transcaucasian Soviet Republic, which embraces the former states of Azerbaijan, Armenia and Georgia. Kars is now included in Turkey.

See republics of ABKHASIA, ADZHARIA, AZERBAIJAN, ARMENIA, GEORGIA, DAGHESTAN and NAKHICHEVAN. Of these republics all except Daghestan joined in 1922 in a Transcaucasian Federation.

History.—On Sept. 20, 1917, a council of Transcaucasian peoples met at Tiflis and declared Transcaucasia to be a Federal republic within the Russian dominions. In May it opened peace negotiations with the Germans and Turks, the latter having invaded the country and captured Batoum and Kars. The Federal Council dissolved, however, on May 26, 1918, Georgia declaring its complete independence and National Councils of Armenians and Tatars taking over the administration of Armenia (Erivan) and Azerbaijan. Separate treaties were signed by Georgia with Germany on May 28 and by the three republics with the Turks and Germans on June 4, which resulted in the "friendly" occupation of Armenia by the Turks and of Georgia by the Germans In the following month the Bolshevik administration at Baku established in March was overthrown and on Aug 4 a British force under Maj-Gen L C Dunsterville occupied the town On Sept 14 they evacuated Baku, which was then occupied by the Turks and became the seat of the Azerbaijan Government. The Turks, however, were compelled to evacuate the whole of Transcaucasia by the terms of the Armistice with the Allies of Oct 30, and in the middle of November, Baku was reoccupied by a British force which administered the district on the collapse of the existing Azerbaijan Government

During 1919 the three Governments gradually established themselves under the protection of the British forces, though Armenia opened hostilities in January against Georgia and in August against Azerbaijan In both cases the disputes (territorial in origin) were settled by British mediation The British forces evacuated the whole of Transcaucasia except Batoum on Aug 28, 1919 In Jan 1920, the Supreme Council sitting in Paris accorded *de facto* recognition to the three Governments On April 27–28 there was a revolution at Baku and the Azerbaijan Government was replaced by a Soviet republic which invited the Russian Soviet forces to occupy the country Georgia and Armenia, however, retained their independence for a time, and the former signed treaties with the Soviet Governments of Azerbaijan (May 7) and Russia (June 6), a step which Armenia refused to take On July 7 the British forces evacuated Batoum and handed over the district to the Georgian Government whose independence was recognized by Soviet Russia in a second treaty signed in August An Armenian Soviet Government was established in December whose independence was recognized by Soviet Russia

On Jan. 27, 1921, the Supreme Council sitting in Paris accorded *de jure* recognition to the Menshevik Government of Georgia, but on Feb 12 there was a rising against this Government in the country and a week later the Russian Soviet troops crossed the frontier Turkish forces then occupied Batoum at the invitation of the Mensheviks, but withdrew on the signature of peace and the proclamation of a Georgian Soviet republic (March 19). In the following May a treaty of Alliance was signed between the Georgian and Russian Soviet Governments Meanwhile the three refugee Governments from Georgia, Azerbaijan and Armenia had fled to Paris and there proclaimed a Caucasian Federation, asserting that the respective Soviet Governments did not represent the wills of the three peoples The three Soviet Governments regulated their relations with Turkey in a treaty signed at Kars on Oct. 13, the provisions of which followed the lines of the treaty concluded in Moscow between Russia and Turkey, March 16. On March 12, 1922, the three Soviet Governments signed an agreement establishing the Transcaucasian S.S.R which, though in close alliance with the Russian Soviet republic, retained independence until the creation of the Union of Socialist Soviet Republics, July 6, 1923, of which it then became a constituent member (*See* Russia.)

TRANSCENDENTALISM is an expression introduced by Kant for "the idea of a science for which the critique of pure reason is to outline the whole plan architectonically. *i.e*, according to principles, with full guarantee of the completeness and security of all the pieces composing this structure" In this sense, it is the system of all principles of pure reason. More precisely, the task of transcendentalism consists in the solution of the question: how are synthetical propositions *a priori* possible, *i.e.*, how can pure intuitions and pure concepts, which are entirely *a priori* and not derived from nor founded on experience, refer to objects of experience and claim for these objects universal and necessary validity? (*Kritik der reinen Vernunft,* 2nd ed p 73) Transcendentalism, according to Kant, is possible only as a system, *ie*, it has to seek its concepts according to a principle because they must issue pure and unadulterated from the understanding as an absolute unity, and must, therefore, themselves cohere with one another according to an idea (*ibid* p 92) As this idea, which establishes and guarantees the coherence between all single cognitions, Kant designates the idea of "possible experience" and an "object of experience" Synthetical judgments *a priori,* whether they belong to the sphere of pure intuition or to the sphere of pure understanding, have the common characteristic that they form those basic functions by which alone it is possible to refer our images to an object and thus to secure for them objective validity In the section "on the supreme principle of all synthetical judgments" Kant shows that this reference to an object is not characteristic of sense impressions as such, but that it is founded on a "synthesis by concepts," *e g.,* the concepts of magnitude, persistence, causality, etc Without such concepts, experience would not be cognition but a mere rhapsody of perceptions which would not enter together into any context of a coherently connected consciousness Cognition *a priori,* accordingly, has truth (*ie*, conformity with the object) only because it contains nothing but what is necessary for the synthetic unity of experience in general. The intuitions and concepts *a priori,* set forth systematically within transcendentalism are, as conditions of the possibility of experience, at the same time conditions of the possibility of the objects of experience and hence applicable to these objects without any restriction (*ibid* p 196 *seq*)

The *term* "transcendental" was not created by Kant The expression goes back to the scholastic philosophy (Knittermeyer *Der Terminus transcendental,* 1920) Here it is synonymous with "transcendent." Transcendental or "transcendent" concepts are such as transcend the realm of finite, conditioned being, and lead on to the Infinite and Unconditioned Only by such a transcendence is metaphysical and religious cognition possible It is necessary to go beyond the variability of finite things and the limits of empirical self-consciousness, if a true knowledge of God is to be reached This use of the word is found already in *Augustine.* In scholasticism, those concepts are called *transcendentia* which are not confined to a specific type of being, but are valid for *all* types Thus the concepts Thing (*res*), One (*unum*), Something (*aliquid*), can be applied to any being Scholasticism gradually developed a fixed order of the *transcendentia* In the *Summa Theologiae* of Albertus Magnus One, True and Good (*unum, verum, bonum*) are introduced as the first essential determinations of being. With Thomas Aquinas, Being is first determined as Thing (*res*) which expresses the "quiddity" or "essence" (*quidditas sive essentia*) of Being; to this are added the concepts One and Something, True and Good (*De Veritate*) *Ens, res, unum, aliquid, verum, bonum,* thus became the "transcendental" concepts of tradition Kant, himself, in the *Critique of Pure Reason,* makes occasional reference to this tradition (2nd ed, p 113)

The new meaning given by Kant to the terms "transcendental" and "transcendentalism," is closely connected with his "revolution in the mode of thinking" In the preface to the second edition of the *Critique of Pure Reason* (p 16) Kant compared this revolution with the change in cosmology effected by Copernicus. "The condition is here the same as with the first idea of Copernicus who, having found that the explanation of the celestial motions did not progress well when he supposed the whole host of stars to turn round the spectator, tried whether it might not succeed better if he made the spectator turn, and left the stars at rest." Thus, in metaphysics, we must not start from a dogmatic assumption about the constitution of *objects* and then determine the mode and character of *cognition,* but, on the contrary, the insight into cognition, into its regularity and structure, must *precede,* and supply the basis for putting and answering the question as to what kind of objects corresponds to that mode of cognition. "If intuition had to follow the constitution of objects, I do not see how one could know *a priori* anything about it, but

if the object (as object of the senses) follows the constitution of our faculty of intuition, I can quite well imagine that possibility." This start from the *mode of cognition*, with the intention of determining the corresponding mode of objects, forms, according to Kant, the basic character of transcendentalism. He calls (*Kritik der reinen Vernunft*, 2nd ed, p 25) all cognition transcendental which is concerned not with objects but with our mode of knowing objects, insofar as the latter is to be possible *a priori*

Transcendentalism, accordingly, does not start with some assumption regarding the essence and constitution of "absolute space," in order to explain the peculiarity of geometrical cognition, but it begins with an analysis of geometry; it shows that all geometry comprises propositions of universal and necessary validity, and it enquires into the "possibility" of these synthetical judgments *a priori*—it investigates "what the conception of space must be, if such a cognition of it is to be possible" (*Transcendental Aesthetic*, §3) The answer to this question is that only if we think of space as an intuition *a priori* can the possibility of the apodictic cognitions of geometry become intelligible Kant emphasises that neither space itself nor any geometrical determination thereof can be called "transcendental"—the term "transcendental" applies rather only to the recognition of the fact that these notions have no empirical origin, and of the possibility by which they can nevertheless refer *a priori* to objects of experience (*ibid* p 80 *seq*) This possibility follows, according to Kant, from the fact that the objects in question are not "things-in-themselves"—not "transcendent" in the sense of dogmatic metaphysics—but phenomena The order and regularity of these phenomena, which we call "nature," does not belong to them independently of the form of our intuition and understanding; but the understanding itself produces this order by connecting the phenomena according to its own laws

Transcendental idealism, therefore, does not reach beyond the sphere of cognition by experience, beyond the realm of the empirical objects, it rather tries to exhibit the foundation of empirical cognition itself In this respect, its use of the word "transcendental" differs, as Kant emphasises, from its older scholastic significance, although even in the *Critique of Pure Reason* it is frequently used in a sense which corresponds to the older view attacked by Kant (A Gideon, *Der Begriff transcendental*, 1903) With particular clearness and pregnancy, the difference appears in Kant's *Prolegomena to any Future Metaphysics*. The word transcendental—it is there declared—does not mean anything which goes beyond experience, but that which, although preceding it (*a priori*), is, nevertheless, only designed to make knowledge by experience possible When these concepts supersede experience, their usage is called *transcendent* The pure forms of intuition, space and time, as well as the categories, as basic concepts of pure understanding, are, therefore, of transcendental *significance*, but not of transcendental *application*; their *validity* is strictly universal and transcends merely empirical incidents, but they extend only to the totality of experience *itself*; they determine its "form," but do not apply to non-empirical, absolute objects In the same manner, Kant determines the concept of "transcendental truth" "In the whole of possible experience lie all our cognitions, and in the general reference to this whole consists the transcendental truth which precedes and makes possible all empirical truth" (*ibid* p 185) (E Cr)

TRANSCRIPTION, in music, is the arrangement of a composition written for one instrument (or group of instruments) for performance by one of another kind, as of an organ work for the piano, of an orchestral work for the organ, and so on

TRANSEPT, in architecture, a transverse section or portion of a hall or building, of considerable relative size, its main dimension being at right angles to the long dimension of the building or hall proper, thus developing a plan of either cruciform or T shape, especially in ecclesiastical architecture, the arms of the church, at right angles to the nave Transepts are found in several of the large early Christian basilicas of Rome, taking the shape of a large, unbroken, transverse hall, whose length is equal to the combined width of nave and aisles, and separated from the nave by a great arch known as the triumphal arch. In the opposite wall an arch of similar size leads into the apse In later basilicas the transept became reduced in importance and the nave ran through unbroken to the apse.

The typical basilica plan, however, has no transept at all, and the transept became a common feature only in Byzantine work from the 8th century, as in S. Mark's at Venice (*c* 1063). It is perhaps due to Byzantine influence that the transept came to be universal in the Romanesque work of France and, less commonly, in Italy In Norman work, both in France and England, transepts were highly developed, frequently designed exactly like the naves, with their own side aisles, triforia and clerestoreys, as in Winchester cathedral (1079–93). These Norman transepts are long; in S Georges at Boscherville (11th century), the north, east and south arms are all equal in length It was probably the opportunity which the transepts furnished for additional altars or for chapels opening out of their eastern sides, as in many Cistercian abbeys, such as Buildwas abbey (1135), that accounts for the universality of the transept. In French examples, outside of Normandy, the projection is frequently less marked, and the transept without side aisles. This became the rule in French Gothic work, in which the transepts often do not project beyond the outer walls of the church, or project slightly

In England, however, long transepts remained the rule until the Perpendicular period, the west transepts at Lincoln (*c* 1200) being 225 ft. long, the transepts of York (1230–60) 220 ft. and those of Lichfield (1220–40) 145 feet In the further effort to increase the number of altars, smaller transepts placed east of the main transept had already appeared in the abbey church at Cluny (1089), and became common in the great abbey churches in England, appearing first at Canterbury (*c* 1170). Other characteristic examples are the eastern transepts of Lincoln (1192), Rochester (*c* 1210). The most beautiful of all are the double transepts of Salisbury (begun 1220) Although the greater number of transepts are square ended, certain occasional examples are apse ended, as in the early basilica at Bethlehem (4th century), S Maria in Capitol and the Holy Apostles (both 12th century, both in Cologne), and the early French Gothic cathedral at Soissons (1175), and that of Noyon (1150) (T F. H)

TRANSFER, the handing over, removal or conveyance of anything from one person or place to another; also the form or method by which it is effected (*see* the articles on LAND REGISTRATION, etc) For the transference of designs, drawings, etc, by means of transfer-paper to the surface of pottery and porcelain, *see* CERAMICS, for their transfer to stones for printing, *see* LITHOGRAPHY

TRANSFER OF STOCKS AND SHARES

Great Britain.—Stocks and shares define the extent of an investor's holding either in a loan to a company, municipality or a government, or in the capital of a company The transfer of stocks and shares is concerned with the formalities that have to be gone through when stocks or shares are bought or sold Usually, this is a question of purchase or sale, but this is not always the case

Three people are directly concerned in every transfer. These are the buyer, the seller and the company or other body which has issued the stock. The buyer has to be assured that the title he acquires is recognized by all concerned, the seller has to be able to prove that he has duly delivered the stock or shares, and the company has to be satisfied that the transfer is a legitimate one, executed in good faith and beyond dispute Other people are concerned indirectly. Thus the buyer and seller always act through agents, such as their solicitor, banker or stock-broker, and the company often employs an agent, such as its bankers, to keep its register of stockholders. Furthermore, when securities are bought and sold on the stock exchange, they may pass through the hands of several intermediaries before they reach the ultimate buyer Finally, the Inland Revenue authorities are concerned, for certain kinds of transfer are liable to duty.

The machinery of transfer is designed to meet the needs of all those mentioned above and to leave no room for dispute. It takes three main forms to suit the three main classes of stocks and shares

(1) **Inscribed Stock.**—Here the names of all stockholders are inscribed in the books kept by the company's or Government's registrar, which is usually a big bank, such as the Bank of England (for British Government stocks) or the Westminster Bank (for certain colonial and corporation stocks). When stocks are bought and sold, the buyer's name is substituted for that of the seller in the registrar's books, which are the sole evidence of possession It is true the buyer gets a "stock receipt," but this is so much "waste-paper" The registrar, of course, has to be satisfied that the transfer is in order Hence he will only act on the instructions of persons known to him. Usually the seller gives his brokers a power of attorney, and as these brokers are known to or can be identified to the registrar, all they have to do is to produce their power of attorney to the registrar as their authority and then the transfer is effected without difficulty. In addition, the seller is notified by post that a power of attorney in his name has been lodged, and is given time to protest if everything is not in order

(2) **Registered Stock.**—Here the stock-holder or share-holder has a certificate showing the nature and extent of his holding, and his name, address and the size of his holding are also entered in the company's share register. The procedure of transfer is different. On a sale being made, the seller's brokers send him a "transfer form," stating the amount and nature of the stock and the price at which it has been sold, and also containing a legal form of agreement as to the sale and purchase This the seller signs in the presence of a witness and returns to his brokers, together with the share certificate. It is then passed on to the buyer's brokers and so to the buyer, who similarly signs it in the presence of a witness It is finally sent with the share certificate to the company's registrar, who, accepting the completed transfer form as his authority, records the transfer and amends the certificate in accordance with the provisions for recording transfers laid down by the company's articles of association

(3) **Bearer Stock.**—Here the possession of the stock or shares by the holder is the only evidence of title required, and so delivery of the stock or shares in question is all that is needed

Certain general points arise. The first is that dealings on the London Stock Exchange are usually "for the account," *i e*, for settlement on every alternate Thursday On this day, stocks and shares must be delivered by the seller to his broker, and the buyer in his turn must pay cash to his broker. Should the seller delay in delivering his certificate and the completed transfer form, his broker may "buy in" the stock against him, and charge the seller with any loss on the repurchase Next, the buyer must not be impatient for his transfer form or share certificate Even after settling day, the form has to come back from the seller be completed by any intermediaries and finally come to him, while many companies provide that transfers have to be passed at the next board meeting before they take effect. Next the transfer form must be filled in and witnessed correctly and without delay, and while, for most stocks and shares, a common form can be used, for some a special form is necessary

Finally, there is the question of transactions "cum" and "ex dividend" A dividend is payable to all stock-holders on a given date, and the purchaser who acquires the stock after that date does not receive the dividend. Hence on that date, the price ceases to be "cum" and becomes "ex div" The same applies to bonus share issues and other privileges or rights belonging to shareholders on a given date, and then the price "goes ex rights" Now the purchaser who buys "ex div" will clearly deduct the dividend from the price he was prepared to pay if he bought "cum div"; thus, if "cum div" price is 88, and the dividend, allowing for income tax, is worth 2¼, the "ex div" price will be 85¾. Now it often happens that a holder will sell "cum div" and that the dividend will be paid before the transfer is registered Then the dividend will be remitted to the seller, but the seller is bound to send it on through his brokers to the buyer.

Stamp duties are borne by the buyer. Bearer stocks and shares are transferred free of duty, but on issue are subject to a duty three times the duty chargeable upon their transfer at par. Inscribed stocks are usually transferable free of duty, as the issuers can and usually do compound the duty by paying a tax of 2s % per annum on the nominal value of the stock The duty on the transfer of registered stocks and shares is normally according to a scale based on a rate of duty of 1% of the price paid, the "price paid" being that paid by the final buyer and inserted on the transfer form in the space "consideration money" When stocks and shares are transferred for a "nominal consideration," *e g.*, from a trustee to his successor or from the holder to his bank who requires them as security for an overdraft or, in certain cases, under the terms of a will, the duty is a fixed one of ten shillings Gifts or exchanges or bequests, where the legatee agrees to accept stock in place of cash, are subject to duty at the normal rate (N E C)

United States.—In the United States the transfer of stock (and it must be remembered that here stock does not signify exactly the same thing that the term does in England, but more nearly has the meaning of the English term "shares") is accomplished quite simply by the transfer of the certificate of stock (*See* STOCKS, SHARES) Such transfer is governed by the Stock Transfer Acts of the several States, most of which have adopted the Uniform Stock Transfer Act. Stock certificates may pass from hand to hand by simple assignment, but in case of sale the purchaser is not a legal stockholder until the stock has been transferred on the books of the issuing company When such a transfer is made the old certificate is cancelled and a new one issued The seller of stock, whose name appears on the face of the certificate, or his authorized representative, must endorse an assignment, which is usually printed on the back of the certificate itself. Such endorsement may be in blank or to a particular person. In all such transfers made on the New York Stock Exchange, it is required that a member of the exchange guarantee the signature of the assignor A bank, trust company or individual may be designated by the issuing corporation as its transfer agent, or its secretary or a special clerk may be given the duty and responsibility of seeing that all transfers are properly made. The several States generally levy a tax upon the transfer of stock The New York State stock transfer tax, which is representative, is 2 cents for each $100 or fraction thereof of stock which has a par value; and a flat tax of 2 cents per share for stock of no par value unless the actual selling value of such stock is in excess of $100 per share, in which case the tax is 2 cents on each $100 or fraction thereof of such selling value (J. H. B)

TRANSFORMATION GROUPS: *see* GROUPS.

TRANSFORMER, an apparatus for changing electrical energy from a given pressure into a higher or lower pressure It is stationary, with no moving or rotating parts, and is operative only with alternating currents It plays such an important part in the transmission and distribution of electricity that the present extensive electrical systems would have been impossible without it Incidentally, since transformers are operative only with alternating currents, all extensive electrical systems have had to adopt the alternating current system so as to use transformers

History and Place in Industry.—Very early in the art it was realized by electrical engineers that, while the generation and utilization of electrical energy are safer and more economical at lower pressures and larger currents, its transmission and distribution are more economical at higher pressure and smaller currents Therefore, in order that a central power house might economically serve even a small territory, it was necessary to have apparatus capable of "stepping-up" the voltage at the point of generation and "stepping-it-down" at or near the points of utilization

Before such an apparatus was invented, physical laboratories used induction coils, similar to automobile spark-coils, for stepping-up battery voltages to high values for experimental purposes, but these were too inefficient for power applications These coils used an open magnetic circuit and required an interrupter, a "make-and-break" attachment, functioning similarly to the distributor in automobile ignition. The necessity for this attachment arose from the fact that currents and voltages could be induced only by fluctuations in flux, and a fluctuating flux could be produced only by a fluctuating current. Therefore, since a battery tended to give a steady uniform current, an interrupter was necessary to produce abrupt changes in current.

It was early realized that if alternating currents are utilized, no interrupter is necessary; and, if the magnetic circuit is made completely closed, the performance characteristics of such a coil are remarkably improved

The first successful transformer was demonstrated by William Stanley in the United States It was put in service in Great Barrington, Mass, in the spring of 1886. Besides for transmission and distribution, transformers are used in a very great variety of services for converting alternating current energy from the pressure at which it is available to the pressure most suitable for the object in view: ringing door-bells, requiring very low safe voltages, welding ship plates, requiring very large currents, operating X-ray tubes, or producing "lightning" bolts requiring enormous voltages Their use in radio for coupling as well as for filament lighting and other power supply is well-known

General Principles of Operation.—*Voltage Transformation* Fig 1 is a simplified diagram of a transformer, showing a closed magnetic circuit M, a lower voltage winding L, and a higher voltage winding H If an alternating voltage is applied to the terminals of one of the windings, say L, leaving the terminals of the other winding, H, open, a small current flows into the excited winding L sufficient to produce a counter voltage equal to the impressed voltage The apparatus in always so designed that the counter voltage is almost entirely one of self-induction, the voltage consumed in the resistance of the conductor usually being less than one-tenth of 1% of this self-inductive drop The voltage of self-induction is produced by an alternating magnetic flux in the core, which in turn is produced by the alternating current flowing in L The relationship between the total or maximum flux and the induced voltage, E_L is

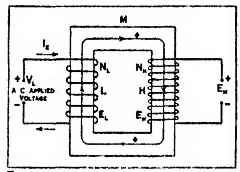

FIG 1—DIAGRAM OF TRANSFORMER WITH SECONDARY OPEN-CIRCUITED (SHOWING INSTANTANEOUS CONDITIONS)

$$E_L = 4.44 f N_L \phi\ 10^{-8}$$

where E_L is the effective (root-mean-square) voltage across L produced by self-induction, f is the frequency of the impressed voltage (periods or cycles per second), N_L is the number of turns in series in winding L, and ϕ is the peak value of the alternating flux ϕ

Obviously, the alternating flux ϕ, linking winding H as well as L, will induce a voltage in H proportional to its turns

$$E_H = 4.44 f N_H \phi\ 10^{-8}.$$

Comparing E_L and E_H, it is seen that

$$\frac{E_L}{E_H} = \frac{N_L}{N_H};$$

that is, the induced voltages of the two windings are directly proportional to their respective turns Thus is obtained the voltage transformation from a given value to another value

Current Transformation—The transformer is now excited but as yet unloaded, that is, no current or power is drawn from it If now a load, with impedance Z, is connected across the terminals of the second winding, H, fig 2, the voltage appearing at its terminals will send a current I_H into the load, equal to

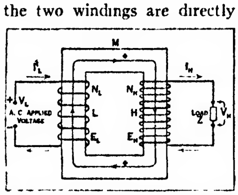

FIG 2—DIAGRAM OF TRANSFORMER WITH SECONDARY LOADED (SHOWING INSTANTANEOUS CONDITIONS)

$$I_H = \frac{E_H}{Z}.$$

This current tends to demagnetize the flux ϕ and thus to reduce the counter E M F of induction But since the voltage impressed on L is maintained at full value, an additional current, I_L, flows into L sufficient to maintain the flux ϕ. This additional current I_L, as also the current I_H, being produced by the load, are called the load currents of the windings, to distinguish them from the no-load current which flows only in the excited winding and which is called *exciting current*

To neutralize the demagnetizing effect of I_H, it is necessary and sufficient that the magnetomotive force or ampere-turns associated with I_L be equal and opposite to that associated with I_H.

$$I_L \times N_L = -I_H \times N_H$$

or

$$\frac{I_L}{I_H} = -\frac{N_H}{N_L}.$$

That is, the load currents in the two windings are inversely proportional to their respective turns, and thus is obtained current transformation It may be noted that current and voltage transformation are in inverse ratio, so that when one is "stepped up" the other is "stepped down" in the same ratio

Energy Relationship—That winding of the transformer on which voltage is impressed and into which energy flows is called the primary, and the other winding, from which energy is drawn out, is called the secondary Either the higher or the lower voltage winding may be used as the primary, and the other as the secondary, so that the operation of a transformer is reversible

The energy flowing into a circuit being proportional to the product of current and voltage, for the load circuit it will be $I_H E_H$, and for the primary circuit $I_L E_L$ By the law of conservation of energy, these two must be equal to each other in an ideal transformer Comparing the values of $I_H E_H$ and $I_L E_L$ from the foregoing, they are seen to be equal and opposite to each other, that is, as much additional energy flows into the primary as is drawn out from the secondary In an actual transformer, some energy is lost within the transformer, so that the energy output is always slightly less than the energy input

Rating of a Transformer.—The type of service for which a transformer is suitable is expressed by its rating, covering usually the following items (1) Kv-a (*i e*, kilovolt-amperes), representing the power capacity, (2) voltages of the various windings, (3) frequency, (4) temperature rise The rating plate usually gives information also with reference to the method of cooling, type of construction, and the proper connections to make

Performance Characteristics.—The degree of excellence of a transformer is indicated by its performance characteristics which usually appear in guarantee specifications as follows (1) exciting current, (2) core loss, (3) copper loss, (4) leakage reactance or impedance, (5) voltage regulation, (6) efficiency, (7) temperature rise, (8) insulation strength Item (5) is a function of item (4), and item (6) is a function of items (2) and (3), so that the controlling independent characteristics are items (1), (2), (3), (4), (7) and (8) The resultant characteristics that interest operators are (1), (5), (6), (7) and (8).

(1) *Exciting Current*—It has been indicated already that the voltages of the various windings of a transformer are induced by an alternating magnetic flux in its core, and that sufficient exciting current flows into the primary winding to produce the necessary flux from instant to instant For a given frequency, terminal voltage and the number of turns, the necessary flux is completely determined by the formula given above The necessary exciting current is then determined with the aid of the characteristic curve of the material used in the magnetic circuit Thus, given the total flux ϕ, and cross-section A of the magnetic core, the flux density B in the core follows as

$$B = \frac{\phi}{A}$$

By referring to the characteristic curve of the core material, the value of the necessary exciting ampere-turns corresponding to the flux density B is obtained This divided by the turns of the excited winding gives the necessary exciting current in amperes. Finally, if this exciting current is multiplied by 100 and divided by the rated load current of the winding, the per cent exciting current is obtained Obviously, the exciting current does not flow into a useful load, and is in a sense wasted. It is therefore desirable that

it be limited to as small a value as possible. In commercial power transformers it is limited to between 1% and 10% of the rated useful load current of the transformer. In miniature transformers, it may greatly exceed the latter limit.

Low exciting current is obtained by using high permeability material for the magnetic circuit, low flux density, short length of magnetic circuit, and greater number of turns per volt in the windings Various alloys of iron (usually silicon-steel) are used on account of their high permeability

(2) *No-Load Loss or Core Loss.*—The alternations of the magnetic flux in the transformer core waste energy (in the form of heat) due to (*a*) hysteresis and (*b*) eddy currents. Both the hysteresis loss and the eddy current loss are found to be very much less in silicon-steel than in many other kinds of iron alloys, and therefore this material is used exclusively for all power and distribution transformers It also shows superior permeability (lower exciting current) compared with common forms of iron at moderate flux densities A further advantage of silicon steel is found in its non-aging quality, while common forms of iron increase in core loss with use The eddy current loss is reduced by laminating the core and insulating the laminations from each other either by oxide scale or preferably by thin enamel. The thicknesses of laminations used commercially are· for 50 to 60 cycle frequencies about 0·014 in , for lower frequencies as much as 0 025 in , and for audio and radio frequencies 0·007 in , or smaller Silicon steel being very hard and somewhat brittle, its rolling into thinner sheets than the above is difficult and expensive In commercial power transformers, the core loss varies from a quarter of 1% to several per cent

(3) *Load Loss or Copper Loss.*—The load currents in the windings, flowing against the resistances of the conductors, produce an energy loss in them equal to I^2R The resistance R is to be understood as the alternating-current resistance, which usually is higher than the direct-current resistance of the winding, due to skin-effect or non-uniform distribution of current among the various filaments of the conductor The copper loss is tested or measured best by short-circuiting one winding of the transformer and putting excitation on the other winding sufficient to circulate the rated current in the windings This test is sometimes spoken of as the impedance test, as it makes possible the measurement of the "impedance volts" of the transformer, as well as its "impedance watts," which is another term used for the alternating-current copper loss of the transformer

(4) *Leakage Reactance or Impedance* —Although the magnetomotive forces in the primary and the secondary windings due to the load currents are equal and opposite to each other, and therefore neutralize each other in any magnetic circuit common to both —for example the steel core—yet they produce leakage fluxes in the spaces between the two coils, giving rise to a *leakage reactance.* This reactance, combined vectorially with the effective resistance of the windings, constitutes the leakage *impedance* of the transformer. Ordinarily, the reactance is many times the resistance of the windings, and hence substantially equal to the impedance. The leakage impedance of a constant potential transformer serves a protective purpose in limiting the short-circuit current of the transformer. However, it produces an undesirable effect in reducing the secondary voltage. (See *Voltage Regulations.*)

The reactance voltage, expressed as a percentage of the rated circuit voltage, varies from 3 to 15%, the lower values occurring in distribution transformers, the higher in the larger power transformers. In order to hold the reactance of a transformer within the range indicated above, the primary and secondary windings have to be closely interlaced If the windings were separated from each other, the reactance would be prohibitively high and the voltage regulation correspondingly poor.

(5) *Voltage Regulation*—Reference to this has already been made. With a constant voltage maintained on the primary of the transformer, the no-load voltage of the secondary is higher than its full-load voltage If the excitation is so adjusted as to make the secondary terminal voltage the full rated value of full-load, and then, without changing the primary impressed voltage, the load is removed, the secondary voltage will rise above the full-load value. This rise is called the regulation drop and is usually expressed as a percentage of the rated full-load voltage.

The regulation is ordinarily calculated as follows: Given %IR, the per cent alternating current resistance, or, better yet, the per cent impedance watts, of the transformer; %IX, the per cent reactance of the transformer; *p*, the power factor of the load, and, *q*, the reactive factor of the load, then,

$$\%\,\text{regulation} = p \times \%IR + q \times \%IX + \left(\frac{p \times \%IX - q \times \%IR}{200}\right)^2.$$

This formula is an approximation but yields more accurate results than some absolute formulae in actual manipulation Fig. 3

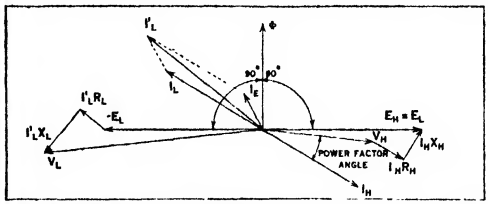

FIG. 3.—COMPLETE VECTOR DIAGRAM OF ONE-TO-ONE RATIO TRANSFORMER

is a vector diagram, showing the various component voltages

(6) *Efficiency*—The total losses of a transformer in power and distribution service vary from about ½ of 1% to about 4%, depending on size, frequency, voltage, etc , making the efficiency vary from 96% to 99 5% It is this fact of high efficiency, coupled with the further fact of the absence of any mechanical motion that has made the transformer a most valuable apparatus and has led to the adoption of alternating currents by most systems

(7) *Temperature Rise*—The maximum load that may safely be put on a transformer is limited by its temperature rise The insulations commonly used in transformers, being largely organic substances, are subject to rapid deterioration under overheat. Temperature limits vary in different countries, ranging from 50° to 65° C rise above the ambient (surrounding) temperature.

(8) *Insulation Strength*—Transformers not only produce higher and lower voltages, but they also insulate one circuit from the other and from ground The safety of both the transformer and the circuits which it links is therefore dependent on the strength of its insulation For rules of various societies on this subject and for methods of making such tests reference may be made to the appropriate literature listed in the bibliography.

Transformer Connections.—For polyphase circuits, a great number of transformer connections have been developed, the standard connections for three-phase circuits being the Y and the delta connections Various connections have also been developed for accomplishing transformation from a polyphase system of a given number of phases to one of a different number of phases, with or without voltage transformation

Structural Classification of Transformers.—When the windings of a transformer surround the magnetic circuit the transformer is *core type;* and when the magnetic circuit surrounds the windings the construction is *shell type.* The windings may be either cylindrical and arranged one inside the other, in which case they are *concentric;* or they may be flat coils and sandwiched in with each other (to obtain reasonably low leakage reactance), in which case they are *interleaved.* The windings may be interleaved with either core or shell type of magnetic circuit The coils may be wound on circular forms, in which case the transformer is said to be of *circular-coil construction;* or they may be wound on rectangular forms, as in the so-called *pancake* or *shell-type* coils

Transformers may be oil-immersed or dry. The former is very desirable for the higher voltage and larger power units for improved insulation and cooling, while the latter is more desirable for miniature transformers for greater convenience. Sometimes considerations of fire risk lead to the use of dry transformers in even large sizes, which then are cooled by an air blast Based on the method used for cooling, transformers may be, (1) *water-*

cooled, in which case cool water is circulated in sealed tubes immersed in the insulating oil filling the transformer case; (2) *air-blast,* in which air is blown by fans through the air ducts of the windings; (3) *air-cooled* or *natural draft,* depending on natural radiation and convection from the exposed surface of transformer or its case; (4) *forced oil,* in which the hot oil is pumped out into radiators, cooled and returned into the transformer; (5) *air-jet cooled,* in which jets of air are blown on the tank and its radiating pipes to break up the stagnant film of air adhering to them and thus to accelerate the cooling by convection of air currents.

Auto-Transformers.—In cases where primary and secondary voltages of a transformer are not very widely different from each other and insulation of the two circuits is not essential, economy can be effected by making some portions of the windings common to both circuits. Auto-transformers used for starting motors at reduced voltage are called *compensators.* (*See* ELECTRICAL POWER TRANSMISSION; ELECTRICITY SUPPLY)

TRANSIT CIRCLE or **MERIDIAN CIRCLE,** a telescope for measuring the time when a star passes across the meridian and at the same time measuring its altitude These two measurements determine respectively the right ascension and declination, and hence the place of the star on the celestial sphere. Because of its fundamental importance in positional astronomy, and as the source of standard time furnished to the community, the transit circle is traditionally regarded as the leading instrument, at least in the great national observatories; but in modern times important observatories have grown up whose work lies wholly in other directions The transit circle looks rather like a big gun on a gun-carriage, and to the stranger the surprising thing about this kind of telescope is that it cannot be turned to all parts of the sky, it only moves up and down in the north and south line, looking out through a slit in the walls and roof. Nor can it be used for prolonged study; the observation is a snap-shot as the object passes rapidly across the field of view

Suppose that we are going to remeasure the exact position of some star We choose from the catalogues a star which is due to pass across the north-south line in a minute or so, and by means of a setting circle we elevate the telescope to the proper angle to catch it. The aperture of the object-glass is probably 8 or 9 in, and it will easily show stars to the ninth magnitude Whilst waiting, let us examine the field of view. Turning on a faint artificial illumination, we see stretched across the field a number of "wires" which are actually made of spider-web; there is one horizontal wire which we can move up or down by turning a micrometer screw, and a considerable number of vertical wires (perhaps ten). Our star now enters the field—at the extreme right since the telescope inverts—and is seen travelling rapidly towards the left. We shift the telescope slightly so as to bring the star almost on to the horizontal wire, and then clamp the instrument at that altitude. Now the star is approaching the series of vertical wires; as it passes each, we press a key which records the instant on a chronograph on which the standard sidereal clock is recording the seconds.

Near the centre of the field there is an intermission which gives us a few moments for making the altitude observation. Turning the micrometer screw, we make the horizontal wire bisect the star, repeating this two or three times to reduce accidental errors. There is no time to read the micrometer head, but it is furnished with some printing or recording device which will keep a record of our settings We now finish tapping off the passage over the vertical wires, and the star disappears from view We have next to go round to the side of the instrument and read four long microscopes which are viewing a graduated circle attached to the telescope Their combined reading will ultimately tell us at what elevation the telescope was clamped; we must add on to that the reading of the micrometer head so as to include the extra displacement given to the wire to bring it on to the star.

The whole observation takes two minutes or less, but there is a great deal of work in store for the computer. He must sort out the taps on the chronograph belonging to this star, and also the records of the micrometer head. The error and rate of the standard clock must be worked up from the "clock stars" observed during the night. The large correction for refraction must be computed and applied to the altitude Various observations for adjustment will have been taken, and from these the collimation, azimuth, level, and zenith-point corrections must be deduced and applied. There will be further corrections, not specially connected with the instrument, to be included before the final place of the star is obtained in the form of mean right ascension and declination This typical procedure may be varied somewhat. The most important modification is the use of the travelling-wire micrometer (*see* MICROMETER), which is now generally employed in first-rate work Attempts have been made to substitute some photographic or photoelectric method for visual observation.

In olden times the altitude observation and the time observation were made with different instruments, called respectively the *mural circle* and the *transit instrument.* The mural circle is obsolete; but the transit instrument survives as a small portable instrument used for determining longitudes and for the most accurate determinations of time. The transit instrument is virtually a transit circle shorn of its graduated circles and microscopes

The transit circle is used for determining the positions day by day of the sun, moon and planets. For stellar work its scope is limited to the brighter stars, roughly those brighter than mag. 9 0 (there are more than 100,000 of these). There is no advantage in observing fainter stars with it, since the work can be done more speedily and accurately by photography; but photographic measures are relative, and the positions can only be made absolute if the photograph contains some "reference stars" whose absolute positions are already known from meridian work Thus transit circle observation is extended only so far as to provide accurate positions of a reasonable number of reference stars on all photographs.

TRANS-JORDAN, a territory under British mandate, bounded west by Palestine, north by Syria, east by Najd and 'Iraq, and south by Hejaz, whose north district ('Aqaba-Ma'an) has, since its occupation by British forces in 1925, been *de facto* included in the mandated area. The Jordan, Dead sea and Wadi 'Araba form the west frontier, from which the land rises abruptly to the mountains (4,000–5,000 ft) of Gilead, Moab and Edom, which are the most fertile parts of the country and produce excellent grapes (for raisins), wheat and other crops. Along the east edge of this highland belt runs the Hejaz railway, beyond which is the desert stretching to the frontier, which is undefined where it marches with 'Iraq and Hejaz and was fixed so far as Najd is concerned by the Treaty of Hadda (1925). Under the Ottoman régime this tract formed part of the Wilayat of Syria, becoming after the World War part of the short-lived Arab kingdom of Syria On Faisal's expulsion by the French in 1920 the three Trans-Jordan districts of 'Ajlun, Balqa and Karak formed a loose semi-independent federation under the general control of British representatives appointed from Palestine In April, 1921, Sharif 'Abdullah, second son of King Husain, suddenly arrived at 'Amman with an Arab force for the invasion of Syria and was recognized by Great Britain as Amir of an independent state comprising the Trans-Jordan districts. At first the Palestine authorities exercised a rigid control over 'Abdullah's administration with the result that intrigues and other more serious trouble occurred In October the experiment was tried of allowing the Trans-Jordan Government a greater latitude, but, after a period of comparative success and tranquillity, 'Abdullah's reckless extravagance and irresponsibility resulted in its failure. A British proclamation of 1923 recognizing the independent status of Trans-Jordan subject to certain conditions never became operative and at the beginning of 1924, after an abortive rebellion of the 'Adwan tribe in Sept., 1923, and further financial complications, the

British Government decided to suspend the experiment and to establish direct control over the more important branches of the administration through British officials directly responsible to the Palestine Government. A considerable increase in the number of British officials and the transfer of the Palestine gendarmerie *en bloc* to Trans-Jordan resulted in fact in the carrying on of the administration on Crown-colony lines and the local government, existing as a façade, exercised little or no independent authority.

The position being thus stabilized, negotiations between the British Government and 'Abdullah resulted in Nov., 1927, in the signing of a treaty, by which the independence of the Trans-Jordan Government was formally recognized with such stringent provisions for British supervision and control in all departments of the administration that all semblance of real independence was effectively disguised In fact, the treaty formally legalized the *status quo*, and the only innovation introduced by it was the provision made for an elective legislative assembly designed to control 'Abdullah but powerless to act in opposition to the mandatory Power. Local feeling has run high against the treaty and 'Abdullah has been accused of betraying the interests of the country for a personal advantage Nevertheless the status of the country and its relations with the Mandatory are for the time being regulated by this instrument which ensures a measure of harmony between the policies, particularly in the economic field, of Palestine and Trans-Jordan. The clauses of the Palestine mandate relating to the establishment of a national home for the Jews do not operate beyond the Jordan, but the plans, now far advanced, for the exploitation of the potash and other contents of the Dead sea, of which half belongs to Trans-Jordan, indicate a settled policy of co-operation between the two countries under effective British control Under this arrangement economic prosperity is assured as a substitute for political independence, and the still exiguous revenues of the country, which are eked out by a British grant-in-aid, should in due course be capable of bearing the whole cost of its administration besides providing much needed funds for development in various directions Occasional trouble between the Badawin tribes of Najd and Trans-Jordan is perhaps inevitable in the process of change that is going on in a desert that knew no frontiers and recognized raiding as a reasonable pastime. Latterly courts of arbitration have been convened for the settlement of such incidents without however achieving much success and much yet remains to be done before the relations of Trans-Jordan with Hejaz-Najd can be regarded as satisfactory

The population of Trans-Jordan is about 300,000 of whom half are Badawin, there are 30,000 Circassians inhabiting a number of colonies planted by the Turkish Government after the Russo-Turkish war of the '70s and about 40,000 Christians of various sects The chief towns are 'Amman (20,000), Salt (20,000), Karak (8,000), Irbid and Ma'an (3,000 each). At the beginning of the Christian era 'Amman (Philadelphia), Jarash (Gerasa), Umm Kais (Gadara) and other places were important centres of Greco-Roman civilization Later Trans-Jordan was part of the territory of the local kingdom of Ghassan and was conquered by the Muslim armies in 637 During the Crusades Karak was an important administrative centre of Oultre-Jourdain. TRANSKEI, one of the divisions of the Cape Province of South Africa, east of the Kei river, being part of the country variously known as Kaffraria, or "the Native Territories" The majority of the inhabitants are Fingoes.

TRANSMISSION LOSS, as applied to radio, indicates the loss of power suffered by a transmitted wave in passing along a transmission path or through a circuit device

TRANSMITTER: *see* MICROPHONE, TELEPHONE.

TRANSMITTING SET, a device for producing radio-frequency power and modifying it in accordance with a signal.

TRANSMUTATION OF THE ELEMENTS. The transmutation of one metallic element into another was one of the chief objects of the earliest chemists, or alchemists, while to-day, under the influence of modern views on the constitution of matter, transmutation has again been attempted in various ways. Between the ancient and the modern tradition, however, there is a complete break, both as regard purpose and method The alchemist was mainly interested to produce, from base metals, gold and silver in large quantities, on account of their intrinsic worth, the man of science of to-day has striven to effect the transformation because of the important light which such a process, however small the quantities involved and whatever the elements concerned, would throw on atomic theory For ALCHEMY *see* that heading The present article is concerned with *Transmutation in Modern Times*

The discovery of radioactivity brought the question of the transmutation of the elements under the serious attention of men of science, and the development of the modern theory of the atom, leading up to Rutherford's experiments on the disruption of the nucleus, seemed to indicate a possibility of producing artificial transmutation The various attempts which have been made along different lines have not led to any convincing success

Radioactive Transmutations and Transmutation Produced by Alpha Particles.—The theory of radioactive transformation, put forward in 1902 by Rutherford and Soddy, associated the emission of α- and β-rays with actual changes in the chemical and physical nature of the atoms emitting the rays, and asserted that in radioactive processes we actually have one element gradually transmuted into another, the number of atoms changing in unit time being a definite fraction λ of the number of atoms present. The value of λ is characteristic of the kind of atom in question It is now definitely established that for each α-particle emitted by a given radioactive element one atom of that element is transformed into an atom of an element whose atomic weight is less by 4, while its atomic number is less by 2, the unit of mass being one-sixteenth the mass of an oxygen atom while, in the case of β-transformations, the atom does not change its mass appreciably, but its atomic number increases by 1 (*See* RADIOACTIVITY, ISOTOPES, NUCLEUS) The change in properties attending this spontaneous transmutation is in many cases very striking Thus radium is an element very much resembling barium, it is a metallic solid at ordinary temperatures, which readily forms halogen compounds Radium emits α-particles and changes to a gas, the so-called radium emanation, or radon, which is, chemically speaking, extremely inert. This gas in its turn emits α-particles and changes to a solid

Although, generally speaking, the radioactive elements are obtainable only in very small quantities, often unweighable, their electrical properties are so remarkable and so characteristic that their identification is certain, while in some cases, notably with radium and its product radium emanation, the quantities are sufficient to enable the physical and chemical properties to be obtained by ordinary means For instance, the spectra of the two elements are radically different. the metallic nature of radium can be seen by inspection of the purified metal. the density of the gaseous emanation has been found by delicate weighings, and the vapour pressure of the liquefied gas measured There is, then, no doubt that in radioactivity we are witnessing a transformation of the elements, but this transformation is outside our control We cannot by heat or cold hurry it or delay it, the rate at which it takes place is uninfluenced by pressure, by chemical combination, or any other agent at our disposal in the laboratory

In the case of radioactive substances we cannot, then, be said to be *effecting* a transmutation of the elements, but merely to be observing one staged by nature However, the great energy of the radiations from radioactive substances, and the marked chemical effects which they can produce at once suggest them as weapons with which to attempt the transmutation of elements normally stable. The α-rays in particular represent so marked a localization of energy that they would appear most likely to be effective in this respect

The first experimental attempts to provoke a transformation by means of the radiation from a radioactive substance were made by A. T. Cameron and Sir William Ramsay in 1907 and 1908 They first found that radium emanation in pure water produced not only helium, but also neon and a trace of argon They also announced that in a solution of copper salts a conversion of a minute part of the copper into lithium took place

as a result of the action of the α-particles. Rutherford and Royds, however, found that emanation in water produced only helium, which is to be expected, for it is now abundantly established that the α-particles are doubly charged atoms of helium. The neon and argon observed by Cameron and Ramsay are attributable to a small leak of air, very minute traces of these gases being detectable by the spectroscope. Other workers were unable to confirm the production of lithium, and it was soon generally accepted that the presence of this metal was due to the admission of traces of impurity, and not to transformation

The difficulty of these experiments is that the amounts of elements supposedly produced by transmutation are excessively minute and the spectroscopic methods used for detection exceedingly sensitive, so that the slightest defect in the manipulation is sufficient to produce a spurious appearance of transformed matter. In 1913 N Collie and H Patterson described experiments which they considered to show that the passage of an electric discharge through hydrogen in X-ray bulbs produced helium and neon, the source of which was supposed to be a transmutation of some one or more of the elements present in the walls of the tube, or of the hydrogen or mercury vapour However, J. J. Thomson and other workers showed that the gases were already in the walls of the tube, and that the action of the discharge was merely to liberate, not to manufacture, them

After this the question of transmutation was left alone for some years, until interest was revived by the experiments of Rutherford on the disruption of atomic nuclei by bombardment with α-particles These experiments are described under NUCLEUS. Rutherford and his collaborators showed by the method of scintillations, which enables single atoms to be observed, that, in the case of certain elements, swift α-particles can knock a proton from the nucleus, the process resulting in the formation of a nucleus of a fresh kind, that is, in a transmutation of the element in question The expulsion of a proton, however, only takes place very rarely, since, for it to occur, the α-particle must strike the nucleus with a full collision, and not at a glancing angle, and the nucleus is very minute compared with the atom itself. Rutherford's calculations, confirmed by the ray-track photographs of Blackett, show that of the incident α-particles only something of the order of 2 per 100,000 produce a disintegration of the nucleus in the case of nitrogen, which means that the whole of the α-rays from 1 gramme of radium in equilibrium with its products (and 1 gramme of radium, costing £20,000 or so, is far more than a physical laboratory can hope to possess) would only transmute about two ten-millionths of a gramme of nitrogen in a year—an unweighable quantity. There is, therefore, no question of producing by this method sufficient transmuted matter for ordinary chemical or physical tests to be applied, and, in fact, although the expulsion of the proton is established beyond doubt in the case of the elements boron, nitrogen, fluorine, neon, sodium, magnesium, aluminium, silicon, phosphorus, sulphur, chlorine, argon and potassium, it is not known what elements are formed when atoms of these elements are so transmuted The uncertainty is as to what becomes of the α-particle If it expels the proton and itself passes on a given atom will be transformed to one whose atomic number is lower by 1, and whose atomic weight is lower by 1. if, on the other hand, the α-particle sticks in the nucleus the resulting atom will have its atomic number greater by 1 than its parent, and atomic weight greater by 3 Blackett's photographs of ray tracks indicate that in the case of nitrogen the latter is the case, so that each nitrogen atom transmuted becomes an oxygen atom, which, having atomic weight 17 instead of 16, is an isotope of ordinary oxygen. On the other hand, the ray-track photographs of Harkins and Ryan, and of Akiyama, taken in air (which comes to the same thing as nitrogen, since no evidence for the disruption of the oxygen nucleus has ever been obtained) show cases of disintegration with tracks of expelled proton, struck nucleus, and α-particle after collision This would indicate that the α-particle does not always stick in the nucleus. This point awaits further elucidation.

Recent Attempts at Artificial Transmutation.—The many lines of work which are described in the articles NUCLEUS and ISOTOPES have confirmed the hypothesis that the nucleus is built up of electrons and protons, the net positive charge of the nucleus giving the atomic number and determining the number of electrons in the extranuclear structure of the neutral atom, and so the chemical properties of the atom, while the number of protons gives the atomic mass. These ideas, and the experiments on nuclear disintegration by α-particles to which reference has just been made, have encouraged many workers to endeavour once more to effect a transmutation of the elements in weighable quantities, or, failing that, in quantities demonstrable by chemical and physical tests. If it were possible either to add an electron to, or to subtract a proton from, the nucleus of an element of atomic number Z, then an element of atomic number Z-1 would be formed. Attempts have been made to effect both these changes As the naturally unstable, or radioactive elements, are the heaviest ones in the periodic table most workers endeavouring to provoke a transmutation have made their choice among the heaviest of the non-radioactive elements, namely the following, the atomic numbers being given in brackets: gold (79), mercury (80), thallium (81), lead (82), bismuth (83). On account of the apparent ease of purification, mercury has been a popular choice.

Nagaoka, studying in detail certain satellite lines in the spectra of mercury and of bismuth, came to the conclusion that these lines were best explained by the hypothesis that the nuclei of these metals contain a single proton slightly detached from the main nucleus, and capable of executing coupled vibrations with it, that is, a proton which, while forming part of the nucleus, is more loosely bound than any other proton or electron of the nucleus He concluded that it might be possible to strike the proton out of the nucleus, and thus effect a transmutation He used purified mercury for his experiments, the method being to pass intense discharges, from an induction coil capable of giving a spark 4 ft in length, between a tungsten wire and a mercury surface To keep the terminal voltage high with the short spark gap used, the mercury was covered with paraffin oil or other suitable oil; the discharge was passed for some hours Nagaoka found gold in the pasty mass of oil and mercury formed, using the ruby glass test for the detection No estimate of the amount of gold so formed was made

Miethe was led to his experiments on transmutation as the result of the observation that when a mercury-vapour lamp, of Jaenicke type, was run with too strong a current a black deposit was formed, in which he found gold There was no particular theoretical reason for anticipating that the experimental conditions adopted would force an electron into the nucleus, but Miethe came to the conclusion that there must be some special state of ionization of the mercury atom produced which was favourable to the transmutation, and, with his assistant, Stammreich, carried out many experiments, in which currents of 12 amperes or so, at a terminal voltage of 170 volts, were passed for many hours through mercury vapour lamps burning at atmospheric pressure These experimenters reported yields of gold up to one-tenth of a milligramme, and also, a fact which is hard to explain on the most fantastic theory, a formation of silver. In later experiments Miethe adopted the method of constantly interrupting the arc, a procedure which he considered to exercise a favourable influence on the formation of gold. Although the amounts of gold found were very small, crystals recognizable under the microscope were obtained, and various tests, such as the streak of fine gold, gave a satisfactory result.

Smits and Karssen endeavoured to effect a transmutation of lead by Miethe's method, and built for the purpose a special lead arc, on the pattern of a mercury vapour lamp, the discharge passing between surfaces of molten lead enclosed in a vessel of quartz glass. Special devices were needed to prevent the lamp breaking when it cooled after running. After the lamp had been in operation for some hours, with a heavy current passing, the spectrum of mercury was observed. With certain conditions thallium was also detected. Smits and Karssen stated that the lead was shown spectroscopically to be free from mercury and thallium before the experiment, but admitted that sometimes the experiment does not succeed, and that the precise conditions for

a positive result are not known. In one successful experiment they reported mercury in quantities of from ·1 to ·2 milligrammes. In the latest communication of Smits (*Nature*, vol. cxx., p. 475, 1927) he describes sparking experiments in which carbon disulphide was used as a dielectric. The traces of mercury obtained in the mixture of dispersed lead and carbon obtained by this method were afterwards traced by him to mercury contaminations in the carbon disulphide.

Another attempted transmutation is that of hydrogen into helium, on which a long series of particularly careful experiments has been made by Paneth and Peters. Calculation shows that this transformation, which demands the combination of four hydrogen nuclei with two electrons to form the helium nucleus, should be attended by a very great liberation of energy, namely 7×10^{11} gramme calories per 4 grammes of helium formed Paneth and Peters have perfected a spectroscopic technique, which permits, in favourable cases, 10^{-10} c c of helium (2×10^{-14} grammes) to be detected They attempted to see if helium could be produced by passing electric discharges of various types through hydrogen, without success They then looked for a formation of helium in the presence of a catalyst, for which purpose they either passed large amounts of hydrogen through heated palladium, or used finely divided palladium to absorb the hydrogen, and after an interval burnt the hydrogen with pure oxygen, at the surface of the catalyser, and examined the residual gases. Helium was found in small quantities, and at first the experimenters believed that it had been formed from the hydrogen Atmospheric air contains minute traces of helium, but a small air leak was ruled out as a source of the gas, as no neon was detected

Pushing their enquiries further, Paneth and Peters discovered that glass in contact with the atmosphere takes up minute quantities of helium, which afterwards leave the glass surface if it be heated in the presence of hydrogen. Once the helium has been driven off in this way the glass is no longer dangerous as a source of helium contamination, but if the glass be exposed once more to the air it again becomes contaminated. Thus the apparent production of small quantities of helium, not only in Paneth and Peters' own work, but also in the experiments of Collie and Patterson and other workers, including the more recent publications of Riding and Baly (1925) is explained. There is no transmutation, but merely a transfer of atmospheric helium into the apparatus by the intermediary of the glass. Paneth and Peters now (1928) state definitely that they have repeated the experiments of all previous experimenters on the formation of helium, with the necessary precautions, and that there is no production of helium amounting to 10^{-10} c.c. in any of them. It may be noted that there is about 5×10^{-6} c.c. of helium in 1 c c. of air, so that the 10^{-10} c.c. which can be detected by Paneth is the amount contained in only one fifty-thousandth of a c c. of air.

Criticism and Conclusions.—It has been shown that claims for artificial production of helium rest upon faulty experimental technique; it may be asked how things stand with the work of Nagaoka, Miethe, Smits and others on the transmutation of mercury and lead.

Here again subsequent workers have been unable to repeat the results, working under apparently the same conditions, and various plausible suggestions have been put forward as to why the original positive results were obtained. Garrett, in particular, has repeated with great care the experiments of Miethe and Nagaoka under a variety of conditions, without being able to detect any formation of gold, although the presence of 10^{-8} grammes of gold would have made itself evident to his tests. He reaches the conclusion that the gold in Miethe's experiments was derived from material in the electrodes and in the vessels. Garrett has further tried to convert tin into indium, and titanium into scandium, by Smits' method, without success. As regards Nagaoka's experiments, the theory has been attacked by Runge, and the experimental work by R. W. Wood, while the isotope of mercury invoked by Nagaoka in support of his theory has since been shown by Aston not to exist. The work of Miethe and Stammreich was extensively criticized at the conference of physicists (Physikertag) held at Danzig in 1925 (see *Physikalische Zeitschrift*, 26, 842, 1925). In short it may be said that no single case of artificial transmutation, in quantities however small, by methods other than the α-ray method of Rutherford, has won acceptance. In the case of the reputed transformations of hydrogen into helium the source of contamination has been traced beyond a doubt; in the other cases where transmutation has been claimed there are no convincing theoretical grounds for supposing the process possible, there are many possible sources of error, and expert experimenters who have repeated the experiments have failed to obtain positive results.

TRANS-OCEANIC AND TRANS-CONTINENTAL FLIGHTS. At Kitty Hawk, North Carolina, on Dec. 17, 1903, Orville Wright (*q v.*) made the first aeroplane flight in history. It lasted only 12 seconds, but before the day was over Wilbur Wright (*q.v.*) completed a flight of 59 seconds duration. Improvements and constant practice enabled the brothers to lengthen these records. In 1905 they made 45 flights, the longest lasting 38 minutes At Le Mans, France, on Sept. 21, 1908, Wilbur exceeded all previous records with a flight lasting 1 hour and 31 minutes which covered a distance of 56 miles. In the same year a number of flights by Henry Farman and Louis Bleriot were made which exceeded 30 miles in length The first notable flight over water was the crossing of the English Channel by Bleriot on July 25, 1909. At the opening of the World War flights of two or three hundred miles were being made.

The War intensified aeronautical activity and provided much spectacular achievement, but distance flying was not the primary aim The development of air-craft during the war-period was immediately apparent in 1919 when aviators, seeking peace channels for the employment of their skill and surplus machines, achieved a number of notable flights. This year, but 16 years after the first flight at Kitty Hawk, witnessed the crossing of the Atlantic Ocean by both aeroplane and dirigible. The first successful flight across the Atlantic was achieved by aviators of the U.S Navy using Navy-Curtiss flying boats. Of the three that started, only one, the NC4, piloted by Commander A. C. Read, completed the trip. Scarcely two weeks after this success Capt. John Alcock and Lieut. Arthur Brown made the first non-stop flight of the Atlantic flying 1,960 miles of ocean between St. Johns, Newfoundland and Clifton, Galway, Ireland, in 16 hours and 12 minutes. Within a month the British dirigible R34 left East Fortune near Edinburgh, Scotland, and crossed to Roosevelt Field on Long Island in four days. Its return trip, even more successful, was made in 75 hours despite fog, squalls and head winds. The flight of Ross Smith from London to Australia inaugurated a number of distance flights by British aviators which were to prove the eventual feasibility of air-lines to distant parts of the empire. The next five years were occupied chiefly by continental flights and by the lengthening of the non-stop distance record. In 1923 the United States was first spanned from the Atlantic to the Pacific in a single flight. The year 1926 was notable for two flights across the North Pole, one by plane and the other by dirigible Lindbergh's perfectly executed flight in 1927 from New York to Paris attracted world-wide attention. The year witnessed three additional crossings of the Atlantic by plane and a

number of tragic failures. It also witnessed the first crossing from the United States to the Hawaiian Islands. Subsequent flights of importance as well as other notable early flights are shown on the accompanying maps. (*See* also AERONAUTICS, AEROPLANE, AIRSHIP, etc.)

TRANSOM, in building, a generic word for many types of horizontal, structural members. Thus in shipbuilding a transom is a form of stern in which the rear end of the boat finishes, not in a series of continuous curves, but in a single transverse plane, which in small boats is formed of a single board; also a built-in berth or bed is frequently termed a transom. In architecture, a transom is a horizontal member across a window or door opening, dividing it vertically into separate portions or lights; in modern doorways the area above such a transom bar, which is sometimes treated as a separate hinged or pivoted, glazed sash, is itself known as a transom. During the mediaeval period, when grouped and traceried windows were frequently of great height, lateral stability to the slender mullions, or vertical dividing strips, which had been furnished in the early Gothic period by iron bars, came in Perpendicular work in England, to be furnished by continuous, horizontal transoms of masonry. These were supported by arches over each light or window division, were usually moulded with a cornice and were occasionally crowned by decorative battlements. In large windows several rows of transoms were used, thus dividing the whole window into continuous horizontal bands of arch-headed lights. (*See* TRACERY.) With the common introduction into secular Gothic work of swinging casements, the use of transoms became general throughout northern and western Europe, in order to keep the size of the swinging sash small, and in Germany, England and France, the use of mullioned and transomed windows continued well into the Renaissance period. (T. F. H.)

TRANSPORT. This subject has been dealt with in separate articles as follows. RAILWAYS, LOCOMOTIVES, TRAMWAYS; ELECTRIC TRACTION, TUBE RAILWAYS, TUNNELS, MOTOR CAR, MOTOR VEHICLES (COMMERCIAL); MOTOR TRANSPORT (COMMERCIAL), TRAFFIC AND TRAFFIC REGULATION; ROAD CONSTRUCTION.

Turning to transport at sea, a series of articles will be found under the headings SHIP; SHIPBUILDING, BARGES AND CANAL CRAFT, SHIPBUILDING. WORLD'S STATISTICS; SHIPPING, HISTORY OF, SHIPPING: *Tonnage;* SHIPPING: *Merchant Ships of the World;* SHIPPING: *Registration, Classification and State Regulation;* SHIPPING LINES; SHIPPING ROUTES; LLOYDS'; LLOYDS' REGISTER OF SHIPPING; and INSURANCE: *Marine.*

As to waterways, a series of articles will be found under the headings CANAL AND CANALIZED RIVERS; RIVER ENGINEERING, LOCK and WEIR. There are separate articles devoted to the PANAMA CANAL and the SUEZ CANAL.

The group of subjects connected with ports and coast protection is treated under PORT, PORT ECONOMICS, PORT OPERATION, DOCKS, DOCKS, FLOATING; HARBOUR, BREAKWATER, COAST PROTECTION, JETTY, PIER, LIGHTHOUSE; LIGHTSHIP, BUOYS.

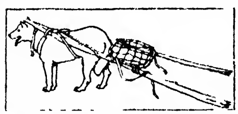
Articles on air transport will be found under AERONAUTICS, AVIATION, CIVIL, AIR ROUTES; and TRANSPORTATION BY AIR.

Below is given a brief general history of the subject.

PRIMITIVE TRANSPORT

Woman was no doubt the first beast of burden, but her training was perhaps due less to her lord and master than to her children. Apes carry their young about, the latter assisting by clinging to the mother's fur with fingers and toes. Human mothers are furless, human babies less prehensile, and many are the contrivances for carrying babies or small children while leaving the hands free. The Eskimo hood, the American papoose frame, the Kafir skin bag, the Chinese yoke, the New Guinea net or the Andaman sling are all baby-carriers, and similar devices may be used for carrying other loads. The daily labours of fetching water and firewood and of collecting roots, berries and other vegetable produce are usually women's work throughout the world; and while the man walks unencumbered save by his weapons, the woman carries all household gear when on the trail. For on the march the man is the hunter and fighter and must have his hands free. S. Hearne's Indian guide Matonabee explained this clearly: "When all the men are heavy laden they can neither hunt nor travel to any considerable distance, and in case they meet with success in hunting, who is to carry the produce of their labour? Women were made for labour, one of them can carry or haul as much as two men." Matonabee himself chose his wives for their strength—"many would have made good grenadiers," says Hearne—and frequently boasted that few women could carry or haul heavier loads. The average woman's load in summer was about 140 lb. and in winter she hauled a greater weight. The Eskimo, a peaceful people who have no special weapons of war, divide their loads fairly evenly between men and women, though the women are usually the stronger, and a tired boy will transfer his load to his sister.

Pack Animals.—The use of animals for transport—the dog, the ox, the horse, the ass, the reindeer, camel and elephant in the Old World, the dog and the llama in the New—marked a great advance, especially as most of the Old World animals were also milk-yielding. The baskets, crates, carrying bags and other appliances could now be removed from the backs of women to those of pack animals, and not infrequently the harness is still the woman's concern, though the man has charge of the pack animal. The distribution of these transport animals depends upon their occurrence in a wild state, their subsequent diffusion, and the distribution of their fodder, or their ability to adapt themselves to varying conditions. The reindeer cannot thrive beyond the limited range of the "reindeer moss" which is their chief food. Unless trained to do so, they will not willingly eat any artificial fodder, or even the moss that has been collected by hand. The llama is confined to the sierras of South America, and the long strings of them that were used for conveying merchandise down to the lower plains soon sickened in the enervating climate. The elephant, owing to his appetite and delicacy, has a restricted range in southern Asia and has not been domesticated in Africa, while in the latter continent the tsetse fly hinders the efficiency of animal transport over the central area.



A DOG USED FOR TRANSPORT BY THE INDIANS OF THE PLAINS IN NORTH AMERICA

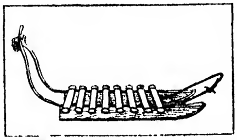
The dog was possibly one of the earliest animals to be used in transport, but owing to its small size and limited strength, it was only trained when no better animal was available. But throughout the Arctic regions of the New and in much of the Old World the dog is invaluable, its light weight enabling it to run over snow-covered ground, and its tractability making good team work possible.

The ox was the most widely distributed of all the transport animals. Various species existed in a wild state in North America, Africa, Europe and Asia, and though the American bison was never tamed, the domestic ox was common in Europe and Asia in the stone age. Whether its first use was for food or for transport is impossible of proof, its flesh was always appreciated, and while its milk would be its chief value to pastoral societies, then as now, its use in dragging the plough would help the agriculturalist in some of his heaviest work. The ox wagon was a familiar means of transport in Mesopotamia and Egypt, as is seen on ancient monuments; it is a common sight round the Mediterranean to-day, and has spread to South Africa and South America, the ox being used in the former continent for riding as well as draught. In Asia the yak is as essential for transport and valued for its milk in the Himalayas as the buffalo in southern India.

The horse still runs wild in large herds over the central Asiatic plains whence the domestic horse is assumed to have been derived. It appears to have been the earliest domesticated animal in Japan where it was ridden, not used for draught, and its westward spread altered the history of Europe, both political and social. Stray horses running wild over the plains and horses deliberately let loose in America soon produced wild herds both in the northern and southern continents, and profoundly influenced the mode of life of the American Indians. The horse is rarely used by the African native, except by those in close contact with the Arabs; drought and heat in the north and the tsetse fly to the south

retarded its distribution and use. Human carriers (men, not women) are the usual means of transport over the greater part of the continent south of the equator as far as the cattle areas, where their place is taken by the ox.

The reindeer provides not only transport, but milk, flesh and skins as well, and a herd of them constitutes wealth in Siberia. Moreover, they support themselves on the "reindeer moss" (*Cladonia rangiferina*) wherever it is not too deeply buried in snow. The Lapp deer are much stronger and more heavily built than those of the semi-wild Chukchi herds in eastern Siberia, which are not strong enough to carry a man, and are not so highly valued for draught. Lapp law forbids a heavier load than 130 lb. on the back and 190 lb. on the sledge. Enormous distances are travelled by Tungus traders with their well trained teams. In early winter, when in good condition after their summer pasturing, a good team will keep up a speed of 10 to 12 miles an hour all day long, and a good bull will travel 150 miles a day if the snow is hard and the temperature some 30 to 40 degrees below zero. No attempt was ever made by the Amerinds to train the American reindeer.



ESKIMO SLEDGE, MADE OF DRIFT-WOOD AND WHALE BONES WITH CARIBOU ANTLERS FOR STEERING

The camel, whether the wild Bactrian camel or the domesticated Arabian (whose ancestry is unknown), with its thirst-defying stomach, its capacity for thriving on desert herbage, and its flat feet spreading out over, instead of sinking into, the soft sand, has made life and wealth possible in the oases of the Sahara. It rivals the horse in the drier districts of Asia from the Holy Land to China, and it has rendered invaluable service in the exploration of the deserts of Australia. The camel fails—apart from the absence of suitable climate or fodder—in the tenderness of its pads over rough, stony, rocky or icy ground. It cannot be shod like a horse, though its feet are often protected by artificial shoes, or pieces of leather are stitched on to its tough soles. The camel provides not only transport, being surpassed in strength only by the elephant and surpassing all other animals in endurance, it supplies milk, flesh, skins, wool and hair. A good riding camel will cover 150 miles in a day, and the baggage camel may carry over 1,000 pounds.

The wild guanaco or mountain camel of South America has a wide range over the higher lands of the continent, but the llama and its relative the paco or alpaca were domesticated and trained for transport only in the Peruvian area. The llama can carry only about 100 lb., and cannot be used for draught, but as they are very docile, a large herd of several hundreds was sent out with merchandise in charge of a few herdsmen, and in the absence of larger animals their value was very high. They still hold their own in high altitudes in competition with mules or donkeys.

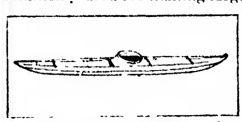
The domestication of the African elephant is doubtful, but the Indian elephant was early trained for transport and for use in war. Its great strength and intelligence can be used to advantage, especially in pathless jungle, and for transporting heavy weights for road and bridge building, but owing to its enormous appetite, which can only be satisfied where vegetation is lavishly abundant, and the delicacy of its constitution compared with ox, horse or mule, its economic value and range therefore are definitely and narrowly limited.

Draught.—Man can drag more than he can carry on his back, and where the surface of the country is suitable some contrivance is made for hauling. The American Indians, if they had no sledges, dragged skins sewn into bags along the frozen ground, and though over the whole of Arctic America packs are carried on the back (human and canine) in the summer, as soon as the ground hardens, sledges are made and far heavier loads can be transported. The Eskimo sledge consists essentially of three pieces, the sides and cross pieces of wood lashed together with raw hide, and the runners or shoes. These are typically of whalebone or walrus ivory (now replaced by iron) pegged on. For winter travel a layer of mud or lichen mixed into a paste is smeared on, coated with ice. The western sledge is 3½ to 4ft. long; the eastern type 12 to 24ft. long according to the locality, with five to nine crossbars. This can carry a load of 1,000 lb. and keep up a steady pace of two miles an hour, drawn by a man, his wife and a couple of dogs. South of the frozen land the toboggan takes the place of the sledge, and in the bison area the special method of packing led to the development of the *travois*. Here the tent poles were fastened into bundles, one on either side of a dog—later a horse—with the ends of the poles trailing on the ground; the skin cover rolled into a bundle was tied on transversely across, and any household goods piled on the top. This suggested the fixed V-shaped framework known as the *travois*. Some such primitive construction preceded the wheeled cart of the Old World, and its last surviving descendants are farm sleds for hauling timber, the sledge on runners used for carting furze in the north of England, or the slide-car used for carting turf in Antrim. The wheel is not a primitive invention as applied to transport, and although wheeled chariots, especially for war, were familiar in early historic times in Assyria and Egypt, there was no wheeled vehicle in America before the discovery of the continent by Europeans.

TRANSPORT BY WATER

This usually requires less effort than transport by land, and is often more highly developed among primitive peoples. The earliest type of boat is the raft, made of grass, logs of wood, bundles of reeds or other light materials tied together, on which man can float. Such was the "raft" of the Tasmanians, made of eucalyptus bark tied in cigar-shaped bundles 9 or 10ft. long, thinning at either end. Similar floating rafts of varying materials were used by early Egyptians on the Nile, and by the Inca on Lake Titicaca. The Jarawa on the small island of South Andaman have no canoes, but lash bamboos together to form rafts for crossing creeks or inlets; the Semang of the Malay Peninsula float down rivers by the same means, returning overland. In Africa, as in Mexico and Peru, large gourds are used for ferrying. On the Hadeija (running into Lake Chad) the Hausa ferrymen, balanced on a calabash, paddle themselves across with arms and legs, earning for themselves the name of *jemage* or "bats"; for transport guinea corn stalks (*Sorghum*) are laid across the calabashes to make a platform. Inflated skins take the place of gourds among the pastoral people of western Asia or north Africa, and inverted pots are used to support the rafts for ferrying across the Nile river. Another primitive type of boat found on the Tigris or Euphrates is the round *gufa*, made of basket-work, covered with skins coated with bitumen which was described by Herodotus (i. 194). The coracles of the ancient Briton, described by Pliny and still used in Wales and round the coasts of Ireland, the skin-covered canoes used by hunters in British Columbia, the "bull-skin boats" in the western States of America are varying developments of the same type.

The finest examples of skin boats are the Eskimo *umiak* and *kayak*. The *umiak* is often called the "woman's boat," but, except in Greenland, it is more used by men than women, and is the boat commonly used for hunting large game. It may be from 10 to 50ft. long, with wide flat bottom, broad spread, and little distinction between stem and stern. The framework, lashed together with sealskin thongs, is covered with large seal skins strongly stitched together and put on green so that they shrink tight. The cover is lashed to the gunwale, and can be tightened as it stretches in getting wet. The *kayak* is seldom used for transport, but is essentially hunting and fishing equipment. It is made in the same way as the *umiak*, but is entirely enclosed in skins save for a small hole. It may be 25ft. long, but is only just wide enough to contain the hunter, who in his waterproof coat slips into the central hole, ties the string of his coat round the rim, and is absolutely impervious in his buoyant craft; he can travel at twice the pace of a two-man canoe, and ventures out



FROM WISSLER "THE AMERICAN INDIAN" (OXFORD UNIVERSITY PRESS)

ESKIMO KAYAK, MADE OF SKIN STRETCHED OVER A TIGHT FRAMEWORK WITH A HOLE FITTING THE HUNTER'S WAIST

in a rough sea. Skin boats are more fitted for temporary than for permanent use; great care has to be taken in beaching them, while, if left in the water, the skins soon rot. Both *kayak* and *umiak* are rapidly dying out.

Where suitable trees of good size are found a simple type of boat is made of a sheet of bark. The Lillooet canoes of British Columbia were formerly always of bark, poplar, cottonwood, spruce, cedar or birch. In the spring two rings were cut round the trunk and a line connecting them, and the bark was pried off in one piece. This was fixed to a wooden framework by sewing with root-fibres, and all the crevices were caulked with moss and gum. The Australian bark canoes are of eucalyptus. A large sheet is peeled off, the ends are turned up, and either tied or sewed, and the joints caulked with resin.

The boat made out of a solid tree-trunk has many advantages. In Melanesia (Kiwai island) there is a tradition of the time when the only craft consisted of a solid log or tree trunk balanced by double outriggers supporting a platform fixed to sticks driven into the trunk. This type may everywhere have been the precursor of the hollowed log, but dug-outs are so widely distributed in time and space that their origins are forgotten. Ancient dug-out canoes, sometimes 50 to 60ft. long, are found in British peat bogs, but it is not possible to date them with any precision, and metal tools were probably used in their construction, though stone adzes are still preferred by the canoe makers of New Guinea.

The Andamanese hollowed out their canoes with shell adzes, without the aid of fire, but they chose soft-hearted wood such as Sterculia, and caulked the ends with beeswax (nowadays they nail up the end with a piece of tin). Some of the finest dug-out canoes are made by the coast tribes of British Columbia. The only tools used in pre-trading days were stone axes, hammers and chisels, and the wood was the native "cedar." To fell the tree, two circular and parallel incisions are made in the trunk, nine or ten inches apart, and the wood is pried or pecked out piece by piece; when it is felled, the length for the canoe is cut off in the same way. It is hollowed out with fire and adze, and roughly shaped. Next fires of smokeless embers are lit near by but not near enough to scorch, and the inside is filled with water brought to a boil with heated stones. This plims and softens the fibre of the wood and allows of the expanding and stretching of the sides, which are fixed in position to the desired width by thwarts pegged in place. Some of the canoes are from 30 to 50ft. long, and will carry 60 to 100 people.

The finest and most varied boats are found among the islands of Polynesia. There are relics of primitive types, rafts of poles lashed together, or bundles of bulrushes, and the Moriori of Chatham island used to venture out to sea, 60 of them at a time, on a raft of flax flower stems (*Phormium tenax*) floating on sea kelp bladders. But beautifully balanced dug-out canoes with or without outriggers and carvel-built plank boats ingeniously lashed together with cord are universal, and in these the long voyages of hundreds of miles from island to island are undertaken. The most imposing of the double canoes were those of the Society islands, the lightest those from Hawaii, and the strongest those of New Zealand. The plank-built canoes were usually made of bread-fruit tree wood (*Artocarpus incisa*) very carefully fitted together.

The whole process of boat-building, from the felling of the trees to the launching of the boat is generally safeguarded by feasts, charms, prayers and varied ceremonies to ensure good luck. Human victims as sacrifices are characteristic both of Oceania and of parts of Africa. Charms are often attached to boats, especially to assist in fishing or in war. An eye painted or incised in the bows, which in Egypt represented the eye of Osiris, is seen round the Mediterranean, off the coasts of India and China, and also North America, still occasionally retaining a magical significance.

HISTORY OF TRANSPORT

Early Inland and Ocean Transport.—Where rivers were available, as in China and Egypt, rafts and boats were used in the early stages of civilization, and it was natural that canals extending or connecting river channels should be dug. The Phoenicians, Greeks and Romans were able to navigate the ocean in vessels equipped with sails and with one to three banks of oars, and it was by means of these craft, that they established and maintained their colonies. The Roman armies and their equipment and supplies were transported to Carthage or Gaul in these boats. The early civilizations developed in river regions with special opportunities of production and transport, and about the Mediterranean, an inland sea providing a navigable highway. Rome built up and maintained a far-reaching empire by military power, by an efficient system of law and administration and by building roads. Without her system of roads, she could not have governed her empire. When the Roman power was overthrown, and road building ceased in Britain, Gaul and Mediterranean lands, economic, social and political life became local. In course of time a feudal society developed that prevailed for centuries. The forces that brought about the change from the feudal to a national organization of society were many, but the improvements in facilities of transport by sea and land were potent factors.

The mariner's compass, though the properties of the lodestone were known in China and India long before they were in Europe, did not have much influence in the East because the Orientals were not maritime people; but in Europe from the 14th century on, mariners could sail by the compass whither they would, and by the end of the 15th century the sailing vessel had carried men to America and around Africa to India. The world was known to be a sphere and the new continent of America had been discovered. The services rendered by the sailing vessel from the 15th to the 19th century in the discovery, settlement and development of new lands, are well known. It is, indeed, remarkable that these slow-going craft of only 80 to 300 tons' capacity could have so influenced the world's history. The largest of the three vessels in which Columbus made the voyage that resulted in the discovery of America, the "Santa Maria," was a decked ship of 100 tons; the "Pinta" and the "Niña" were caravels of 50 and 40 tons respectively. It took from Aug. 3 to Oct. 12, ten weeks, to make the passage via the Canary islands to Watling's island in the Bahamas. The sailing vessel provided a transport unit and facility appropriate to the commercial requirements of the 17th and 18th centuries. Trade, still in large part barter, was in small quantities, and the ships were in most instances operated by the merchants in the conduct of their business. Traders could advantageously send the small vessels of that day to shallow harbours as well as to deep ones. The common carrier, as distinct from the merchant, operating vessels over fixed routes did not become general until the 19th century.

Road and Canal Building in the 17th and 18th Centuries.—France was the leader among European countries in developing a modernized inland transport system. The work was begun in 1597 by Sully, who made a start with the task of creating a national system of roads surfaced with broken stone. The great road-builder of France, however, was Colbert, who became comptroller of France in 1661. By enforcing the feudal system of compulsory labour of all able-bodied peasants he brought about the surfacing of 15,000m. of road. The roads thus built were not scientifically constructed and maintained. In 1775, Tresaquet, by making provision for drainage of the roadway, began the construction of better roads and he substituted a continuing force of paid workers in place of the intermittent labour under the *corvée* system. Two Scotsmen however, Thomas Telford (1757–1834) and John Loudon MacAdam (1756–1836) were the first to build roads according to the scientific methods that have been followed to the present day, emphasizing the necessity of providing a well-drained roadway.

Telford's practice was to lay a base of large stone on which smaller stones were placed, the surface being made of finely broken rock. MacAdam began with crushed rock a few inches in diameter, and omitted the foundation of large stone. He showed that the angular surfaces of crushed rock, when pressed together by a heavy roller, would give to a layer a few inches in thickness strength sufficient to sustain the load that is ordinarily imposed on a highway. The MacAdam road was thus lighter and less expensive to construct than the Telford road. The MacAdam foundation is still used in road building, although there may be a binding of cement and the surface may be a layer of asphalt or of concrete. Great Britain has until recently looked to the parishes and counties to construct and maintain public roads. From 1760 onward parliament chartered a large number of turnpike companies which built toll roads after the crude manner that prevailed until near the end of the 18th century, when Telford and MacAdam began their work In 1763 a stage coach journey from London to Edinburgh required 14 days

This situation in Britain was first ameliorated by the construction of canals, the first of which, promoted by the duke of Bridgewater to connect Worsley, and thus Liverpool, with Manchester, was opened in 1761. This canal reduced the cost of coal in Manchester 50% The 3,000 m. of canals constructed in the British Isles between 1760 and 1830, the rapid improvement of the highways from 1800 on and the development of railways after 1825 made it possible for England, in advance of other European countries, to market factory-made goods in large quantities at home and abroad, and thus to establish an economic and commercial leadership, which, until recent years, she maintained without serious challenge England's maritime supremacy was established before the Napoleonic wars, and from 1815 to the present her merchant marine has provided her world-wide commerce with ample transport facilities.

England was not the first country to construct modern canals, Holland began first. France emphasized canal building for two centuries and by connecting her main rivers and improving their channels created a national system of inland waterways. Germany, like France, has made large use of her natural waterways, but their improvement came mainly during the latter part of the 19th century The waterways contributed to the economic development of many other countries, including the United States during the 19th century, but the rôle they have played has been a minor one in comparison with those of the railroad, the ocean steamship, and latterly, of the automobile, the bus and the truck.

The Railway, Its Economic Significance.—The introduction of the locomotive and the railway inaugurated an economic and social revolution. It gave man the service of a power capable of indefinite technical development to assist him in expanding his economic activities and his social contacts The railways, followed and supplemented in turn by the steamship, telegraph, telephone, electric railway, automobile, aeroplane and wireless communication, have during the past 100 years transformed the world. Changes have come with accelerating rapidity until there seems to be no limit to the degree of world unity made possible by developments in transport and communication.

Though it would seem that a century of technical progress would have brought the locomotive to the limit of its mechanical possibilities, improvements in power efficiency and fuel economy have been more rapid since the World War than during any previous decade. Among the innovations of the last sixty years are: (1) The rolled steel rail which began to be laid about 1870 made possible the construction of a track capable of withstanding the strain of the heaviest and fastest trains; (2) trains could not be safely run at high speed until they were equipped with power brakes. George Westinghouse successfully applied the air brake to passenger trains in 1868 and to freight trains in 1887. The air brake reduced by 90% the time and distance required to stop a train by hand brakes; (3) the transport of fresh meat and fruit was successfully accomplished during the 1870's with the refrigerator car Fresh meat from cattle reared on the ranches of the United States, Canada, Australia, Argentina and Brazil has, by refrigeration on land and at sea, been made marketable at all places reached by organized transport. Likewise fresh fruit, and more recently fresh vegetables, are marketed hundreds and thousands of miles from the orchards, vineyards or plantations where they are produced; (4) the operation of freight trains on regular schedule and at increased speed may seem to be a matter of small consequence, but it is placing production and merchandising upon a new basis. The merchant does not now have to carry a large quantity of goods nor does the manufacturer have to stock up with large amounts of materials and supplies Business is done with a smaller amount of inactive capital, productive activity and the employment of labour are more continuous, (5) as it is by the application of power that the work of transport is done, power efficiency determines the progress made by transport The technical achievements of recent years give promise of great advances in the future in connection with all transport facilities—railways, electric railways, ocean vessels, motor vehicles, aeroplanes and airships

The Ocean Carrier and Its Development.—On the ocean, as well as on the land, rapid changes are taking place in the mechanism and services of transport and these changes are affecting industrial and commercial conditions on a wide scale. The wooden sailing vessel gradually gave way to the steel steamship during the first three quarters of the 19th century. Fulton's "Clermont" inaugurated steamboat navigation on inland waterways in 1807; the "Royal William" made the first transatlantic voyage solely by steam power in 1833; the screw propeller was invented in 1836; and the iron hull dates from about 1840 The Inman line adopted the propeller in 1850, and the Cunard line in 1862 The "Great Eastern," the giant of its time (1869), had not only a screw propeller, but paddle wheels, and six masts for sails. Twin screws were first used on warships in 1880 and on a passenger vessel in 1888 Steel began to take the place of iron in hull construction about 1880

The relatively slow technical development of the ocean vessel was largely due to the limitations of the marine engine. The engines with low steam pressure and consequently long slow piston stroke could be used to drive paddle wheels by direct crank shaft action, whereas gearing and loss of power were involved in giving the propeller the requisite speed While direct acting engines were used to drive propellers as early as 1854, it was after 1870 that the present type, the inverted, direct acting, compound steam engine came to be exclusively used; then the ocean vessel developed rapidly in speed, size and economy of service. The conspicuous, much advertised passenger liners attracted most public attention, but their influence was small in comparison with that of the slow freight steamers, often called "tramps," which after 1870 could move cargo so cheaply as to make possible the shipment, for practically any distance, of bulk cargoes of grain, coal, ore, lumber, phosphate rock and the other essentials of industrial expansion

The ocean vessel and ocean transport are undergoing revolutionary changes, due to the invention of the internal combustion engine, the use of oil for fuel, and the operation of freight vessels less as individual units and more in line services with scheduled sailings The turbine, which had been invented in 1883–84, was introduced in warships and large high speed ocean vessels about 1900; but while the turbine was superior to the reciprocating engine for some purposes, its use did not involve a fundamental change such as accompanied the introduction of the internal combustion engine named after its inventor, Rudolf Diesel. The Diesel engine does away with the boilers and furnaces, it occupies less space than steam equipment and thus adds to available cargo capacity It consumes much less fuel, gives a vessel a much greater sailing range and is more economical to operate. For these reasons it is being so largely adopted for vessels of moderate size and speeds that ocean shipping promises to be motorized in large part in the relatively near future. The check upon the general Dieselization of shipping thus far has been the higher cost of installation and the weight of the Diesel engine and its auxiliaries, but these handicaps are being steadily

overcome by designers and builders

The Electric Railway.—Electric power has been employed in three fields of transport, for city street railways, surface, elevated and underground, for interurban railways, and, to some extent, as a substitute for steam locomotives on railroads in large city terminals, tunnels and on heavy mountain grades where current can be generated by water power

When the motor-bus appeared on the city streets a few years ago, the electric railways were supplying all organized urban transport, and supplemented by suburban extensions they had in three decades, by providing rapid transit, caused cities to spread out over ever enlarging areas and had done much to improve living conditions for the constantly increasing number of people who live in cities The importance of the interurban electric railway has been greatly reduced by the rapid development of motor-bus service. Many interurban, and also suburban electric lines have ceased to operate in the United States, and in most countries the suburban and local passenger traffic of steam railways, especially in the United States, has been greatly reduced mainly by the extensive use of private automobiles and also by the competition of motor-buses Indeed local and short distance passenger transport seems to be steadily transferred from the steam and electric railways to the highways

At the beginning of this century it was thought that steam railways would be electrified, there being no question as to the general superiority of electricity as a motive power, but electrification has thus far been confined mainly to tunnels, to eliminate the smoke and gases, to a few large city terminals, also for the same reason, and to some mountain grade sections where electric locomotives are more efficient than steam and where current can usually be obtained from water-power The general electrification of steam railways in the near future is not probable for the reason that the cost of the change would so increase the investment in the railways as to make impossible a profitable rate of return on the increased capital Moreover, the steam locomotive has of late improved rapidly in power, efficiency and economy and has made electrification seem less important than formerly The application of the Diesel engine has great possibilities

Highway Transport—the Automobile Age.—The movement for good public roads began in western Europe 100 years before it started in the United States, a newer country with a sparser population and less accumulated capital Moreover, the early and wide-spread development of railways in the United States provided facilities for other than short-distance and local transport that were fairly adequate until near the end of the 19th century. Then it became manifest that in the more thickly populated north-eastern States improved county and State roads were necessary New Jersey acted first, adopting a State highway law in 1890, Massachusetts, New York and some other States soon followed with similar acts The movement, however, would probably have been much slower than it was, had it not been for the automobile, the use of which rapidly increased after 1900 and particularly from 1910 onward, until at the present time there are as many automobiles in the United States as there are families The demand of the private automobile owners throughout the United States for roads that are good throughout the year was strengthened during and after the World War by the operators of motor-buses and of motor trucks, whose use for local passenger and freight transport had increased with great rapidity The States (aided from 1915 by the Federal Government) have provided the country with a comprehensive system of State and inter-State highways The improved highway and the automobile in the United States have brought mechanical transport to each man's door, and the same is true in varying degree in many other countries.

The effect of making mechanical transport universally available has been to create new conditions of living, to increase economic activity, to stimulate wider intellectual interest, to raise standards of living Possibly the immediate consequences of the sudden change from a relatively static to a highly mobile society may not all be advantageous, but mankind may be expected to adjust itself to the new order of things and to meet successfully the social problems of the automobile era, as it has met the difficulties that have arisen in the past.

Air Transport and Its Effects.—No other facility of transport is receiving so much attention from the public and from technical experts as the aeroplane. The great interest aroused in aeronautics—in the aeroplane and the airship—by the World War has continued unabated, the aim of present efforts (1929) being to establish air transport of passengers and high class package freight, as well as the mails, upon a self-supporting commercial basis. For a discussion of this subject *see* TRANSPORT BY AIR. (E. R. J.)

TRANSPORT, MINISTRY OF: *see* GOVERNMENT DEPARTMENTS.

TRANSPORT BY AIR. Aircraft were first used on regularly scheduled routes in Germany where for four years prior to the World War Zeppelin airships carried passengers between the larger cities Immediately after the war British aeroplanes were employed in a passenger service between London and Paris. Soon all other large nations had their own air-transport, though with the exception of the United States, they were compelled to grant liberal subsidies to maintain the lines in continuous operation

The first scheduled air-mail service was started by the Post Office Department in the United States May 15, 1918, using military planes on the initial route between New York and Washington, D C. The trans-continental route between New York and San Francisco was then opened, and in 1926 was lighted for night flying between New York and Omaha, Neb.

In accord with the Federal policy that the Government should not engage in private business the Post Office Department relinquished the mail routes to private contractors under the provisions of the Kelly Act of 1926 That legislation is credited with having established air-transport on a self-sustaining basis By its terms the Post Office Department lets mail contracts at a pound rate This form of indirect subsidy has supported the operators through the early years of experiment, permitting them to develop better equipment, train their personnel and cultivate popular patronage.

The Air Commerce Act of 1926 was another agency calculated to develop air-transport. It created a law for licensing planes and pilots, regulating all civil flying and maintaining the American airways under the Department of Commerce The Aeronautics branch of that department charts routes, equips airways for night flying, establishes lighted beacons and radio communications in much the same manner as other bureaux provide ports, lighthouses and other navigational aids for surface vessels

On Jan. 1, 1929, there were 15,128 miles of airways in the United States, two-thirds of their aggregate distance lighted and prepared for night flying. Twenty-two companies were operating 33 air-mail routes under contract with the Post Office Department Mail planes were flying an average of 27,848 miles every 24 hours

Ten other air-transport companies were carrying either passengers or express, or both With 13 of the mail operators, which also carried passengers and express, these American lines transported 52,934 passengers on scheduled flying service in 1928; that was about four and a half times the number flown in the preceding year The average fare was 10 cents a mile

The year 1928 was the first in which the companies carried express under contract with the American Railway Express Company, and the amount flown during the twelve months was 1,222,843 pounds. The contract air-mail lines carried 3,632,059 pounds of mail, thrice the poundage of the preceding year The 33 operating companies flew more than 10,000,000 miles in 1928.

Air-transport in the United States had progressed to such a stage in 1929 that close observers felt warranted in recognizing it as of equal importance with terrestrial transportation First and last this importance is based on speed, the dispatch with which persons and things can be carried from one place to another without delay

The cargo planes in 1929 were averaging about 125 miles an hour; and that, admittedly, was not fast enough to take traffic

away from the surer surface transport An average speed of 150 miles an hour for passengers and 175 miles an hour for mail and express would, it was believed, result in popularizing air-transport and placing it on a par with the railroads and motorbuses.

Such speeds, along with the solution of several technical problems, were promised for the near future; and the engineering genius of the nation was at work toward that end.

In Europe the record of air-transport is vastly different. There are no great distances within the limits of a majority of European countries, hence no especial need for such speed as the aeroplane alone can provide. In the British Isles train and bus service has been entirely adequate The cross-Channel air service between London and Paris would not be profitable if operated without liberal subsidies. It is maintained primarily because it is an important section of the air-transport system which Britain is establishing between London, Egypt, the Near East, South Africa and India. Eventually, it is believed, passengers will be carried on those routes in giant airships, while fast planes will be used to carry mails and urgent express.

The French Government maintains its military aviation facilities by supporting the aeroplane industry, buying military machines for the air forces and commercial planes for the operating companies. The operation of the French air lines was so generally unsatisfactory late in 1928 that the Government adopted a policy of reorganization, uniting and regrouping the principal subsidized lines and stipulating the degree of service they must render. French lines operating throughout Europe, across the Mediterranean to Africa and in South America, by connecting with steamship service between French Africa and Brazil, were designed primarily to maintain a great reserve force for the French defensive establishment The same condition existed in Italy, where the Fascist policy was to create air highways for exactly the same purpose as the Roman roads were built, to facilitate communications of a political nature

The German Government and a majority of the German States grant liberal subsidies to the commercial air-transport lines, the principal one being the Deutsche Luft Hansa, the largest, most popular and profitable air-transport system in Europe. Luft Hansa aeroplanes operate between all German centres and make connections with those of other nations at practically every large city in Europe Night flying had not progressed to any extent anywhere on the Continent at the beginning of 1929.

Among the problems remaining to be solved before air-transport may be considered equally practicable with surface methods is the development of aeroplane radio to a degree where it can be made available for direct conversation between the pilot in the machine and persons on the surface, this in order that he may be kept constantly informed of his location in darkness, storm or fog, that he may be warned to swerve from his course and head for some other field where it may be advisable for him to land, especially when there is fog at his original destination Thus far there is no device enabling a pilot to make a safe landing in fog, no matter if he knows he is directly over his airport

With the widespread development of municipal airports the change of course is not so much of a problem, so far as safety is concerned; but it does affect the comfort and convenience of passengers For example, one bound for New York does not like to find oneself set down in Philadelphia because of fog at the other terminal That was the chief problem awaiting solution in 1929.

A most important phase of air transport in 1929 was the development of air-rail service whereby the air lines and the railroads might work together in a co-ordinated system, flying passengers and express part of the way and for the remainder taking them aboard trains In both the United States and Europe the railroads had accepted in principle the idea that the faster vehicle might be of the greatest value in reducing operating costs, not as a competitor but as a supplementary carrier.

If the railways could succeed in removing from their rights-of-way all fast trains, no small part of the maintenance costs would be eliminated because the fast traffic requires much more repair, supervision and greater safeguards

Instead of setting up their own private air lines to compete with air transport companies, the railways were joining with the existing lines, rearranging schedules, locating terminal and transfer facilities, training personnel and generally paving the way for a completely equipped air-rail service. A majority of the railroad executives were hopeful that the day might soon arrive when they would be able to entrust to aircraft all of their fast, long-distance passenger traffic

With the long trunk line systems fairly established in practically every country there remained the establishment of short haul or feeder lines, and considerable progress was being made in that direction in all countries The linking together of all communities within a nation's boundaries was promised for an early date That would make air transport a distinctly national institution

Following that there must develop international routes connecting all countries. Expert opinion holds that the airship must become the common carrier for all long distance routes over the water, principally because it can carry heavy loads at a greater net profit; also because it can remain in the air, supported by buoyant gas, even when the engines fail For shorter distances over water and routes overland within a radius of 1,000 miles the aeroplane is superior and more profitable. There is every indication that the two types, heavier and lighter-than-air, will be employed together within the next five years, airships and planes being used to link all countries in one vast system affording a continuous world-wide service travelling at an average of 100 miles an hour or even better in any kind of weather (H M)

TRANSUBSTANTIATION, the term adopted by the Roman Catholic Church to express her teaching on the subject of the conversion of the Bread and Wine into the Body and Blood of Christ in the Eucharist Its signification was authoritatively defined by the Council of Trent in the following words "If any one shall say that, in the Holy Sacrament of the Eucharist there remains, together with the Body and Blood of Our Lord Jesus Christ, the substance of the Bread and Wine, and shall deny that wonderful and singular conversion of the whole substance of the Bread into (His) Body and of the Wine into (His) Blood, the species only of the Bread and Wine remaining—which conversion the Catholic Church most fittingly calls Transubstantiation—let him be anathema" (Sess xiii *can* 2) The word Transubstantiation is not found earlier than the 12th century. But in the Eucharistic controversies of the 9th, 10th and 11th centuries the views which the term embodies were clearly expressed, as, for example, by Radbertus Paschasius (d 865), who wrote that "the substance of the Bread and Wine is efficaciously changed interiorly into the Flesh and Blood of Christ," and that after the consecration what is there is "nothing else but Christ the Bread of Heaven" The words "substantially converted" appear in the formula which Berengarius was compelled to sign in 1079 We may take it that the first use of the word is in a passage of Hildebert de Savardin (d 1133), who brings it into an exhortation quite informally, as if it were in common use. It is met with in a Decretal of Innocent III The fourth Lateran Council fully adopted it (1215) It is clear from the treatise of Radbertus Paschasius already quoted that the word "substance" was used for *reality* as distinguished from *outward appearance*, and that the word "species" meant *outward appearance* as opposed to *reality* The terms, therefore, were not invented by St Thomas Aquinas, and are not mere scholastic subtlety The definition of the Council of Trent was intended both to enforce the accepted Catholic position and to exclude the teaching of Luther, who, whilst not professing to be certain whether the "substance" of the Bread and Wine could or could not be said to remain, exclaimed against the intolerance of the Roman Catholic Church in defining the question

Bibliography.—For a full and recent exposition of the Catholic teaching on Transubstantiation the reader may consult *De ecclesiae sacramentis*, auctore Ludovico Billot, S J. (Rome, Propaganda Press, 1896) *See* also the *Catholic Encyclopaedia*, article "Transubstantiation" The Abbé Pierre Batifol, in his *Études d'histoire et de théologie positive*, 2me série (*Elaboration de la notion de conversion*, and *Conversion et transubstantiation*) treats it from the point of view of

development (V. Lecoffre, Paris, 1905). (J. C. H.; X.)

TRANSVAAL, an inland province of the Union of South Africa between the Vaal and Limpopo rivers. It lies, roughly, between 22½° and 27½° S. and 25° and 32° E, and is bounded on the south by the Orange Free State and Natal, on the west by the Cape Province and the Bechuanaland Protectorate, on the north by Rhodesia, and on the east by Portuguese East Africa and Swaziland Save on the south-west the frontiers, for the main part, are well defined natural features From the south-west to the north-east corners the colony is 570 m; east to west its greatest extent is 397 m The total area is 110,450 sq.m, a little less than the area of Great Britain and Ireland.

PHYSICAL FEATURES

About five-sixths of the country lies west of the Drakenberg (*q v*). The boundary of the Transvaal over against Portuguese East Africa runs along the Lebombo Range, between which and the Drakenberg is a belt of low country The Lebombo Hills approach within 35 m. of the sea at Delagoa Bay. The part of the plateau, east of Johannesburg, is from 5,000 to 6,400 ft high; the western and somewhat larger half is generally below 5,000 ft and sinks to about 4,000 ft on the Bechuanaland border. This plateau land is called the high veld, and covers about 34,000 sq m The northern edge of the plateau follows an irregular line from somewhat north of Mafeking on the west to the Mauchberg on the east This edge is marked by ranges of hills such as the Witwatersrand, Witwatersberg and Magaliesberg; the Witwatersrand, which extends eastward to Johannesburg, forms the watershed between the rivers flowing to the Atlantic and Indian Ocean. Farther north, beyond the intervening slopes and low bush, are two elevated regions covering together over 4,000 sq m They are the Waterberg, and, more to the east, separated from the Waterberg by the valley of the Magalakwane tributary of the Limpopo, the Zoutpansberg An eastern offshoot of the Zoutpansberg is known as the Murchison Range The low land between the high veld and the Waterberg and Zoutpansberg is traversed by the Olifants River, an east flowing tributary of the Limpopo.

The true high veld, extending east to west 120 m, and north to south 100 m, consists of rolling grass covered downs, absolutely treeless, save where, as at Johannesburg, plantations have been made by man, the crest of the rolls being known as *builts* and the hollows as *laagtes* The surface is occasionally broken by kopjes—either table-shaped or pointed—rising sometimes 100 ft. above the general level Small springs of fresh water are frequent and there are several shallow lakes or pans—flat bottomed depressions with no outlet The largest of these pans, Lake Chrissie, some 5 m long by 1 m broad, is in the south-eastern part of the high veld The water in the pans is usually brackish The middle veld is marked by long low stony ridges, known as rands, and these rands and the kopjes are often covered with scrub

The banken veld, formed by the denudation of the plateau, is much broken up and is rich in romantic scenery. It covers about 27,000 sq m, and has an average breadth of 40 m In places, as between Mafeking and Johannesburg, the descent is in terrace-like steps, each step marked by a line of hills; in other places there is a gradual slope and elsewhere the descent is abrupt, with outlying hills and deep well-wooded valleys The rocks at the base of the slopes are granite, the upper escarpments are of sedimentary rocks. Thence issue many streams which in their course to the ocean have cut their way across the ranges of hills which mark the steps in the plateau, forming the narrow passes or *poorts* characteristic of South African scenery.

As in the middle veld, rands and kopjes occur in the low or bush veld, but the general characteristic of this part of the country, which covers over 50,000 sq m, is its uniformity. The low veld east of the Drakenberg begins at about 3,000 ft. above the sea and slopes to 1,000 ft or less until it meets the ridge of the Lebombo hills The lowest point is at Komati Poort, a gorge through the Lebombo hills only 476 ft above the sea. West and north of the Drakenberg the general level of the low veld is not much below that of the lowest altitudes of the middle veld, though the climatic conditions greatly differ. North of the Zoutpansberg the ground falls rapidly, however, to the Limpopo flats which are little over 1,200 ft. above the sea. Near the northwest foot of the Zoutpansberg is the large saltpan from which the mountains get their name The low veld is everywhere covered with scrub, and water is scarce, the rivers being often dry in winter.

River Systems.—There are four separate river basins in the Transvaal Of these the Komati (*q.v.*) and its affluents, and the Pongola and its affluents rise in the high veld and flowing eastward to the Indian Ocean drain but a comparatively small area of the province, of which the Pongola forms for some distance the south-eastern frontier. The rest of the country is divided between the drainage areas of the Vaal and Limpopo The absence of alluvial deposits of any size is a characteristic of the Transvaal rivers. For the climate of the Transvaal *see* SOUTH AFRICA, UNION OF.

Vegetation.—Forest patches are confined to deep kloofs, to the valleys of the larger rivers and to the seaward slopes of the Drakensberg and other ranges, where they receive mists and rains from the moisture laden winds. Many trees have been introduced and considerable plantations made, as for instance on the slopes between Johannesburg and Pretoria Among the most successful of the imported trees are citrus trees, the Australian wattle and the eucalyptus. Grassland is the prevalent association in the province. (*See* SOUTH AFRICA, UNION OF)

Fauna.—When first entered by white men the Transvaal abounded in big game, the lion, leopard, elephant, giraffe, zebra and rhinoceros being very numerous, while the hippopotamus and crocodile were found in all the rivers The indiscriminate destruction of these animals has greatly reduced their numbers. Shooting is now restricted by legislation In the Pretoria Game Reserve and in the Kruger National Park shooting and hunting are absolutely prohibited The latter was formed by the amalgamation of the Shingwedzi and Sabie Reserves. It covers over 20,000 sq m in the low country, and promises to be one of the finest nature reserves in the world

Insects abound, the greatest pest being the tsetse fly, common in the low veld Six species of tick, including the blue tick common throughout South Africa, are found, especially in the low veld, where they are the means of the transmission of disease to cattle Mosquitoes, locusts and ants are also common

Population.—The population in 1921 included 543,485 whites, who had increased by 1926 to 608,622. A large proportion of these live on the Witwatersrand, on the coalfield or in Pretoria The natives in 1921 numbered 1,495,869 Apart from the large numbers employed in the gold and coal mines, the natives are found chiefly in the northern part of the province. Basuto are numerous in the Zoutpansberg and Lydenburg districts. Bechuana are largely confined to the west and south-west. Amazulu are found principally in the Wakkerstroom and Standerton districts, and Amaswazi in the Barberton, Ermelo and Wakkerstroom districts Shangaan and other East Coast tribes form an appreciable element in Barberton, Lydenburg and Zoutpansberg Asiatics totalled nearly 16,000 They are largely engaged in trade, and are settled on the Witwatersrand, in Pretoria and Barberton The number of mixed and others was 32,291. These include a few Hottentots and Koranna, who live chiefly in the south-west of the province. (*See* SOUTH AFRICA, UNION OF, and separate articles on the several tribes.)

Towns.—Pretoria is the administrative capital of the Transvaal, and of the Union of South Africa. The city of Johannesburg is the largest urban agglomeration in the Union. Germiston and Boksburg are virtually suburbs of Johannesburg. Among the other towns are Potchefstroom, Klerksdorp, Middelburg, Barberton, etc. (*See* separate articles.)

Mineral Resources.—The Transvaal, the principal gold producing country in the world, is noted for the abundance and variety of its mineral resources The minerals chiefly mined besides gold are diamonds and coal, but the country possesses also platinum, silver, iron, copper, lead, cobalt, sulphur, saltpetre and many other mineral deposits.

Gold.—The principal gold-bearing reefs are found along the

Witwatersrand ("The Rand"). Probably connected with the Rand reefs are the gold-bearing rocks in the Klerksdorp, Potchefstroom and Venterskroon districts Other auriferous reefs are found all along the eastern escarpment of the Drakensberg and are worked in the De Kaap (Barberton) district, on the Swaziland frontier, in the Lydenburg district, in the Murchison Range and in other places in the Zoutpansberg Goldfields also exist in the Waterberg and on the western frontier in the Marico district (the Malmani fields) The total value of the gold extracted from mines in the Transvaal from 1884 to 1926 was £885,841,707. (*See* also South Africa, Union of. *Geology*)

Diamonds—The chief diamond fields are in the Pretoria district The ground was discovered to be diamondiferous in 1897, but it was not until 1903, when mining began on the Premier mine, situated 20 m north-east of Pretoria, that the wealth of the fields was proved In June 1903 mining began and the diamonds found in the first five months realized over £90,000 On the 27th of January 1905, the largest diamond in the world, weighing 3,025¾ carats, over 1⅓ lb avoirdupois, was found in the mine and named the Cullinan The Premier mine is of the same character as the diamond mines at Kimberley (*see* Diamond), and is considerably larger The area of the "pipe" containing blue ground is estimated at 350,000 sq yd

Besides the Pretoria fields there are diamondiferous areas (alluvial diggings) in the Bloemhof district on the Vaal river northeast of Kimberley, and in other regions In 1926 the whole output of diamonds in the Transvaal was valued at £4,487,921.

Platinum—In 1924, in the Lydenburg district, a bed of norite, an igneous rock in the Bushveld Igneous Complex, was found to contain platinum, the quantity varying from 2 to 5 pennyweight per ton The outcrop of this bed has been traced for about 60 miles In 1925 platinum bearing rocks were recognised near Potgietersrust The Bushveld norite has also been traced in the Rustenberg area for about 100 m At present production is only in the experimental stage

Coal and Other Minerals—There are extensive beds of good coal, including thick seams of steam coal near the Rand and other goldfields. Coal appears to have been first discovered in the neighbourhood of Bronkhorst Spruit between the Wilge and Olifants rivers, where it was so near the surface that farmers dug it up for their own use In 1887 coal was found at Boksburg in the East Rand, and a mine was at once started The principal collieries are those at Boksburg and at Brakpan, also on the East Rand, with a coal area of 2,400 acres, at Vereeniging and Klerksdorp, near the Vaal, at Watervaal, 12 m north of Pretoria, and in the Middelburg district, which now supplies most of the coal used by the gold mines. Like that of Natal the Transvaal coal burns with a clear flame and leaves little ash. The mines are free from gas and fire damp and none is more than 500 ft. deep The output in 1926 was over seven and a half million tons

Iron and copper are widely distributed The Yzerberg near Marabastad in the Zoutpansberg consists of exceedingly rich iron ore, which has been smelted by the natives for many centuries. Silver is found in many districts, and mines near Pretoria have yielded in one year ore worth £30,000

Salt is obtainable from the many *pans* on the plateaux, notably in the Zout(salt)pansberg, and was formerly manufactured in considerable quantities

Agriculture.—Next to mining, agriculture is the most important industry The chief occupation of the majority of the white farmers is stock-raising The high veld is admirably adapted for the raising of stock, its grasses being of excellent quality and the climate good. Even better pasture is found in the low veld, but there stock suffers in summer from many endemic diseases, and in the more northerly regions is subject to the attack of the tsetse fly The banken veld is also unsuited in summer for horses and sheep, though cattle thrive Much of the stock is moved from the lower to the higher regions according to the season. Among the high veld farmers breeding of merino sheep is popular

The amount of land under cultivation is very small in comparison with the area of the province. The small proportion of land tilled is due to many causes, among which paucity of population is not the least. Moreover while large areas on the high veld are suitable for the raising of crops of a very varied character, in other districts, including a great part of the low veld, arable farming is impossible or unprofitable. Many regions suffer permanently from deficient rainfall, in others, owing to the absence of irrigation works, the water supply is lost, while the burning of the grass at the end of summer, a practice adopted by many farmers, tends to impoverish the soil and render it arid The country suffers also from periods of excessive heat and general drought, while locusts used to sweep over the land, devouring every green thing In some seasons the locusts, both red and brown, come in enormous swarms covering an area of 5 m broad and from 40 to 60 m long. The chief method employed for their destruction is spraying the swarms with arsenic. The districts with the greatest area under cultivation are Heidelberg, Witwatersrand, Pretoria, Standerton and Krugersdorp. The chief crops grown for grain are maize (mealie), kaffir corn and wheat (*See* South Africa, Union of) Maize is the staple food of the natives Oats, barley and millet are largely grown for forage Oats are cut shortly before reaching maturity, when they are known as oat-hay The chief vegetables grown are potatoes, pumpkins, carrots, onions and tomatoes Fruit farming is a growing industry on the slopes of the plateaux and in the warmer valleys, where citrus and other sub-tropical fruits thrive, as, for example, about Rustenberg, Waterberg, etc In 1925 there were nearly two million orange trees in the province, mostly navel oranges Grapefruit trees numbered about 27,000, peach trees 33,000, and apple trees nearly 200,000 Apples, and, to some extent peaches thrive better in the higher districts These figures refer to trees, the fruit of which is mostly grown for export

Cotton growing is making satisfactory progress The number of morgen under this crop in 1919–20 was 3,275 in 1925–26 it had increased to nearly 28,000 Cotton grows well in the western part of the Transvaal, north of the Magaliesberg Range, and in the low veld of the north and east, where frost is absent for six or seven months Tobacco is grown in the Magaliesberg area, and about Potchefstroom, the cultivation of over 7,000 morgen in 1926 yielding nearly eight million pounds of tobacco

There are few manufacturing undertakings other than those connected with mining, agriculture and the development of Johannesburg There is a large factory for the supply of dynamite to the gold mines The building and construction trade is an important industry on the Rand, where there are also brickworks, iron and brass foundries, breweries and distilleries There are a number of flour mills and jam factories in various centres A promising home industry, started under English auspices after the war of 1899–1902, is the weaving by women of rugs, carpets, blankets, etc, from native wool Iron and steel works have been established at Vereeniging and Pretoria

Provincial Government.—At the head of the executive is a provincial administrator, appointed by the Governor-General-in-Council. He holds office for five years, and is assisted by an executive committee of four members elected by the provincial council The provincial council consists of 50 members, elected for the same constituencies and by the same electorate as are the members of the House of Assembly The provincial council, which has strictly local powers, sits for a statutory period of three years.

Education.—Since 1910 education, other than elementary, is under the control of the Provincial Council At the head of the permanent staff is the Director of Education The province is divided into 31 school districts, in each of which is a school board, consisting partly of elected and partly of nominated members: its functions are advisory Both primary and secondary education are free Attendance is compulsory for European children between the ages of 7 and 15. The age limit has been raised to 16 in 27 of the school districts Religious teaching is confined to the undenominational instruction in Bible history In 1926 there were over 1,200 State and State-aided schools for Europeans, and 435 for non-Europeans Many of the latter are directed by missionary bodies (For higher education, religion, and defence *see* South Africa, Union of) (F R C; R U S)

HISTORY

At the beginning of the 19th century the country now known as the Transvaal was inhabited, apparently somewhat sparsely, by Bavenda and other Bantu negroes, and in the south-west by wandering Bushmen and Hottentots About 1817 the country was invaded by the chieftain Mosilikatze and his impis who were fleeing from the vengeance of Chaka, king of the Zulus The inhabitants were unable to withstand the attacks of the disciplined Zulu warriors—or Matabele, as they were henceforth called—by whom large areas of central and western Transvaal were swept bare The remnants of the Bavenda retreated north to the Waterberg and Zoutpansberg, while Mosilikatze made his chief kraal at Mosega, not far from the site of the town of Zeerust, and near the Bechuana border At that time the region between the Vaal and Limpopo was scarcely known to Europeans In 1829, however, Mosilikatze was visited at Mosega by the celebrated missionary to the Bechuana, Robert Moffat and between that date and 1836 a few British traders and explorers visited the country and made known its principal features Such was the situation when Boer emigrants first crossed the Vaal

FOUNDATION OF THE REPUBLIC

As shown elsewhere (*see* South Africa, Union of and Cape Colony) the Voortrekkers had an intense desire to be rid of British control, and to be allowed to set up independent communities and govern the natives in such fashion as they saw fit The first party to cross the Vaal consisted of 98 persons under the leadership of Louis Trichard and Jan van Rensburg They left Cape Colony in 1835 and trekked to the Zoutpansberg Here Rensburg's party separated from the others, but were soon afterwards murdered by natives. Trichard's party determined to examine the country between the Zoutpansberg and Delagoa bay Fever carried off several of their number, and it was not until 1838 that the survivors reached the coast Eventually they proceeded by boat to Natal. Meantime, in 1836, another party of farmers under Andries Hendrik Potgieter had established their headquarters on the banks of the Vet river Potgieter and some companions followed the trail of Trichard's party as far as the Zoutpansberg, where they were shown gold workings by the natives and saw rings of gold made by native workmen. They also ascertained that a trade between the natives and the Portuguese at Delagoa bay already existed On returning to the Vet, Potgieter learned that a hunting party of Boers which had crossed the Vaal had been attacked by the Matabele, who had also killed Boer women and children This act led to reprisals, and on Jan. 17, 1837, a Boer commando surprised Mosilikatze's encampment at Mosega, inflicting heavy loss on the Matabele without themselves losing a man—for the Boers had, and the Matabele had not, firearms In November of the same year Mosilikatze suffered further heavy losses at the hands of the Boers, and early in 1838 he fled north beyond the Limpopo, never to return Potgieter, after the flight of the Matabele, issued a proclamation in which he declared the country which Mosilikatze had abandoned forfeited to the emigrant farmers After the Matabele peril had been removed, many farmers trekked across the Vaal and occupied parts of the district left derelict Into these depopulated areas there was also a considerable immigration of Basuto, Bechuana and other Bantu tribes

The first permanent white settlement north of the Vaal was made in Nov 1838 by Potgieter and some followers who settled on the banks of the Mooi river and founded the town of Potchefstroom The next settlement appears to have been in the Magaliesberg, where Rustenburg was founded At that time the emigrant farmers had set up the republic of Natal; in 1840 Potgieter's party entered into a loose alliance with the Natal Boers and with those at Winburg, north of the Orange. In this alliance Natal had the leadership, but in 1843 the British annexed Natal and in the following years many burghers left that country, recrossed the Drakensberg, and set up an independent Government in the Transvaal. Dissensions among the immigrants broke out almost at once and in 1845 Potgieter, with a considerable number of Potchefstroom burghers and some from Winburg migrated north-east towards Delagoa bay, where Potgieter made a treaty with the Portuguese A spot on the inner slopes of the Drakensberg was chosen as headquarters and there was built the village of Andries Ohrigstad. It proved fever-ridden and was abandoned, a new village being laid out on higher ground and named Lydenburg by the farmers in memory of their sufferings at Ohrigstad Other emigrants settled in the Potchefstroom district and in 1848 Andries Pretorius (*q.v.*) became their leader. Pretorius, in the middle of that year, had fought unavailingly against the establishment of British sovereignty by Sir Harry Smith (*q.v.*) between the Orange and the Vaal The Transvaal thus became the refuge of the most irreconcilable to British rule of the Dutch farmers—who were, however, much more pastoralists than agriculturalists

Sand River Convention.—Pretorius persuaded the more responsible farmers to agree to one *volksraad* for the whole country, but Potgieter, by nature a dictator, would not agree and he and his friends removed from Lydenburg farther north to the Zoutpansberg However the British Government abandoned its claim to regard all the emigrant farmers beyond the Vaal as British subjects Commissioners sent to the Orange Sovereignty opened negotiations with Pretorius and on Jan 17, 1852, a convention was signed at a farm by the Sand river, in the Orange Sovereignty, acknowledging the independence of the Transvaal without regard to the divisions among the Boers The first article of the Sand River Convention was as follows.—

> The assistant commissioners guarantee in the fullest manner, on the part of the British Government, to the emigrant farmers beyond the Vaal river, the right to manage their own affairs, and to govern themselves according to their own laws, without any interference on the part of the British Government, and that no encroachment shall be made by the said Government on the territory beyond to the north of the Vaal river, with the further assurance that the warmest wish of the British Government is to promote peace, free trade, and friendly intercourse with the emigrant farmers now inhabiting, or who hereafter may inhabit, that country, it being understood that this system of non-interference is binding upon both parties

At this time there were settled north of the Vaal about 5,000 families of European extraction They had obtained independence, but as has been shown they were far from being a united people. When Pretorius conducted the negotiations which led to the signing of the Sand River Convention, though he had the support of the Rustenburg and Lydenburg districts, he did so without consulting the *volksraad,* and Potgieter's party accused him of usurping power and aiming at domination over the whole country However, the *volksraad,* at a meeting held at Rustenburg on March 16, 1852, ratified the convention, Potgieter and Pretorius having been publicly reconciled on the morning of the same day Both leaders were near the end of their careers; Potgieter died in March and Pretorius in July 1853

The Constitution.—Upon the death of Andries Pretorius his son Marthinius was (Aug 1853) elected commandant-general of the Potchetstroom and Rustenburg districts, he had been in office little more than six months when the Orange Sovereignty was abandoned by the British and the Orange Free State as an independent republic took its place. Martinius Pretorius was a man of large ideas and he worked for the union of the Boer States First he had to start with his own country. In 1855 the town of Pretoria was founded and the Pretoria district created; in 1856 the burghers of Potchefstroom, Rustenburg and Pretoria united to form "the South African Republic." The title was chosen, a national flag (the *Vierkleur*) adopted and the constitution (*grondwet*) elaborated at a special session of delegates held in December at Potchefstroom It was decided that Pretoria should be the capital of the State The legislative power was given to a *volksraad,* elected by the burghers (that is the franchise was confined to white men); the administration was entrusted to a president aided by an executive council which included a popularly elected commandant-general. Members both of the *volksraad* and council were to be of European blood and members of the Dutch Reformed Church. A high court of justice separate from the *volksraad* was instituted. The constitution further expressly declared that no equality of coloured people with the white inhabitants would be tolerated either in Church or State Paul Kruger, then a

man of 30 and leader of the Rustenburg burghers, took a leading part in framing the constitution

The Civil "War."—At the time both Lydenburg and Zoutpansberg repudiated the authority of the South African Republic of which, as a matter of course, Pretorius was elected president (Jan 1857). The same year Pretorius, with Kruger's aid, tried unsuccessfully, by means of an armed raid, to compel the Free State to join the S A R Pretorius nevertheless retained many supporters in that State. Not long afterwards the efforts of the British high commissioner, Sir George Grey, for a federation of all the South African states came to nothing Pretorius now secured the incorporation of Lydenburg and Zoutpansberg in the S A R A vacancy occurring in the presidency of the Free State, Pretorius was elected He went to Bloemfontein with the fixed object of uniting the two Boer republics He found, however, discontent in the Free State, a depleted treasury and much trouble with the Basutos Moreover the British authorities frowned on proposals for the union of the O F S and the S A R Old rivalries broke out in the Transvaal, and the country presented the spectacle of two rival presidents, or acting presidents, and two rival Governments This in turn led to a sort of civil war, though without actual fighting There was a "bombardment" of Potchefstroom —with one gun—by Paul Kruger and on that occasion three lives were lost and a few burghers wounded In this conflict Kruger supported the side which he held to be the legal government and called his force the army of the State (*staatsleger*) Pretorius intervened more than once; at last in April 1863 he resigned his presidency of the Free State, but in the Transvaal a new election resulted (Oct 1863) in the return of W. J C van Rensburg as president (Rensburg had been one of the acting-presidents since April 1862, his rival being Stephanus Schoeman, the Zoutpansberg commandant-general, a son-in-law of Potgieter) The Pretorius party declared van Rensburg improperly elected and brought their *volksleger* (people s army) into the field under Com J Viljoen Kruger called out his *staatsleger* and seeing that he was being outmanoeuvred determined to fight in earnest "He shot to kill and ended the civil war" (Walker's *History of South Africa*) The parties now in fact came to terms, a new election was held and this time Pretorius was returned at the head of the poll, while Kruger became commandant-general On May 10, 1864, Pretorius took up the presidency again In February John Brand had become president of the Free State and he succeeded in making it a model commonwealth Pretorius lacked the ability and solidity which distinguished Brand and he had even more intractable human material with which to deal

Church Controversies: the Doppers.—Political dissension had been accompanied by ecclesiastical strife Practically all the burghers were members of the Dutch Reformed Church, but the Cape synod of that Church had disapproved the *trek* and the emigrants had been left almost without ministers They were, however, deeply religious in a narrow Calvinistic fashion, and in all their settlements built a church even though without a minister Their literature was almost confined to the Bible, many of them looked upon themselves as the chosen people on a new pilgrimage, so that church affairs filled an important part in their lives After much controversy it was decided in 1853 that there should be no incorporation of the Transvaal churches with the Cape Synod; for one thing the Transvaalers objected to the legal equality of blacks with whites permitted in the colonial churches.

In 1858–59 another cause of dissension arose There was already in some strength among the burghers the sect of Doppers, who contended that while hymns were good spiritual aids in private devotion, they should not be sung in church, not being (like the psalms) part of holy scripture. In 1858 the Rev. D Postma, of the Separatist Reformed Church of Zwolle, Holland, became minister at Rustenburg and at once gained the support of all the Doppers. At a general assembly at Pretoria in Jan. 1859 Postma refused to use hymns, and Kruger and other laymen gave notice that they had left the *Hervormde Kerk* (the Dutch Reformed Church) and proposed to form a new church Efforts at compromise failed and later in the year the Separatist (Dopper) Church was formed Its official title is *Christlijk Afgeschiedene Gereformeerde Kerk*. During the civil war Kruger got the constitution altered so that a member of any Reformed Church might hold full political rights

From the first, whatever their internal dissension, the Transvaal Boers had vast territorial ambitions; at an early stage they even put forward a claim to all the land north of the Vaal from ocean to ocean, and they repeatedly and persistently tried to get an outlet to the sea One of their earliest claims, made a few weeks after the signing of the Sand River Convention, was to the land of the Bechuana, and Andries Pretorius asked the British to close the "lower road," that is the route to the far interior opened up originally by the missionaries, Moffat and Livingstone This request was followed (Aug 1852) by a raid on the Bakwena Bechuana—who were said to be harbouring a chief who had looted Boer cattle. In this "punitive expedition" Livingstone's house at Kolobeng was looted, and some 200 to 300 women and children carried off by the Boers The struggle for Bechuanaland thus begun lasted for nearly 40 years, ending in the discomfiture of the Boers (*see* BECHUANALAND)

The Slavery Charge.—The action of the commandos against the Bakwena brought against the Boers the charge of slavery, and the apprentice law passed by the *volksraad* in 1856, it was alleged, practically legalized slavery It must be remembered that when the Boers first emigrated to the Transvaal, slavery had been but recently abolished in Cape Colony, Potgieter and others of the *Voortrekkers* may have been slave-owners, but slavery as such was not recognized in the Transvaal The organized native tribes with whom they had dealings were usually required to produce a "labour tax" in kind; that is, the chief had to furnish labourers to perform specific work There was no great hardship in this. But many farmers on the borders of the old Cape Colony had had a habit of kidnapping Bushmen children and others and "apprenticing" them together with other apprentices obtained in a more legitimate fashion This reprehensible habit persisted among the Boers in the Transvaal—among whom were many bad characters who had no claim to be farmers and who were not all of Dutch blood The apprentice system was in existence in other parts of South Africa, and almost inevitably led to abuses The Apprentice Law of 1856 in the Transvaal was an effort to mend matters It provided safeguards against misuse of power, that it had to be repeated three or four times showed how its provisions were disregarded The apprentices were usually small children, exchanged for goods by their parents "picked up starving" on the veld "orphans" (a plentiful supply), young persons obtained from tribes fighting one another, children, in short, obtained in any fashion, in 1864 Martinus Pretorius is reported as asking the Landdrost of Zoutpansberg to buy him half-a-dozen little Kafirs at a time when the Swazis were raiding The worst feature of the system was that there was a regular traffic in apprentices This practice, forbidden by the law, made of apprentices goods and chattels Thus the charge of practising virtual slavery was justified Towards the natives in general the Transvaalers adopted an attitude of modified indifference, they had their locations and could manage their own tribal affairs as long as they provided the farmers with the needed labour; missionaries among them were tolerated, but the Boers made no attempt to produce a civilized class of African But they adopted very stern measures against misdoers Thus in 1854 to avenge the murder of a party of Boers (including women and children) M Pretorius led a commando against the chief Makapan, many of whose people, who had taken refuge in caverns, were smoked or starved to death and many others shot while attempting to escape. This chastisement kept the tribes quiet for years.

When in 1864 M. Pretorius again became president the Transvaal was suffering from the depression which at that time affected the whole of South Africa, and it had trouble with the Zulus, with the Bechuana, and with the powerful tribes in the Zoutpansberg Schoemansdal (named after Com.-gen Schoeman) in the Zoutpansberg, was then the most important settlement of the district. In 1867 Schoemansdal and a considerable portion of the district were abandoned on the advice of commandant-gen-

eral Kruger, and Schoemansdal was burnt to ashes by natives It was not until 1869 that peace was patched up, and the settlement arrived at left the mountain tribes in practical independence.

Meanwhile the public credit and finances of the Transvaal had gone from bad to worse The paper notes, issued since 1865, had been constituted by law legal tender for all debts, but in 1868 their power of purchase was only 30% compared with that of gold, and by 1870 it had fallen as low as 25% Civil servants, who were paid in this depreciated scrip, suffered considerable distress The revenue for 1869 was stated as £31,511; the expenditure at £30,836

Territorial Disputes.—While the situation was very sombre there came the discovery of diamonds in Griqualand and of gold at Tati, and again the claims of the Transvaal to territorial expansion were put forward. Following the discoveries at Tati, Pretorius, in April 1868, issued a proclamation extending the Transvaal frontiers on the west and north so as to embrace the gold field and all Bechuanaland The same proclamation extended Transvaal territory on the east so as to include part of Delagoa bay The eastern extension claimed by Pretorius was the direct sequel to endeavours made shortly before by a Scotsman from Natal (Alex McCorkindale) to develop trade along the Maputa river But it was also part of the old desire of the Transvaal Boers to obtain a seaport, a desire which had led them as early as 1860 to treat with the Zulus for the possession of St Lucia bay That effort had, however, failed And now the proclamation of Pretorius was followed by protests on the part of the British high commissioner, Sir Philip Wodehouse, as well as on the part of the consul-general for Portugal in South Africa The boundary on the east was settled by a treaty with Portugal in 1869, the Boers abandoning their claim to Delagoa bay; that on the west was dealt with, partially, in 1871

Disputes on the Bechuana border had been constant; they became again prominent by the discovery of alluvial diamonds in the strip of land between the Vaal and Harts rivers, to the sovereignty of which there were rival claims A little later the famous dry diggings on the De Beer and other farms were discovered They were south of the Vaal and to them the Orange Free State laid claim. But there was a rival claimant in the Griqua chief, Nicholas Waterboer, and since 1862 the Griqua claims had been urged by his agent David Arnot, a clever Cape Colony attorney, who in the end bluffed all his opponents The various claims including those of the Barolong Bechuana to land north of the Vaal where, as at Bloemhof, Transvaal authority was in fact exercised, were submitted to the arbitration of R W Keate, lieutenant-governor of Natal His award was made in Oct. 1871, and was admittedly just on the evidence produced It gave Waterboer all he claimed—though he had no title whatever to the diamond fields—and the Barolong, an area which the Transvaal actually held Now Waterboer, before the arbitration court met, had offered his territory to Great Britain and it was known to all the parties that the offer would be accepted Accordingly a few days after the publication of the Keate award, Sir Henry Barkly, the high commissioner, took over as British territory Waterboer's land (*see* GRIQUALAND) This included the triangular piece of land above the confluence of the Vaal and Harts rivers, in which diamonds had first been found. As to the land awarded to the Barolong, no steps were taken to enforce the Keate award; the Transvaal Boers remained in possession of Bloemhof and all the farms they held—and disputes with the Bechuana continued

President Burgers.—The award caused a strong feeling of resentment among the Transvaal burghers and led to the resignation of President Pretorius and most of his executive. The burghers now cast about to find a man who should have the necessary ability, as they said, to negotiate on equal terms with the British authorities should any future dispute arise They asked President Brand of the Free State if he would come over and rule them. Brand declined, telling the Transvaalers—greatly perturbed though he was by the loss of the Kimberley diamond fields—that their true interests lay in friendship with, not in hostility to, Great Britain and the British Having failed with Brand, the Boers invited the Rev. Thomas François Burgers, a member of a well-known Cape Colony family and a minister of the Dutch Reformed Church known to be of "liberal" views in theological matters, to allow himself to be nominated. Burgers accepted the offer, and in 1872 was elected president. About this time gold reefs were discovered in the Zoutpansberg district near Marabastad, and a few gold seekers from Europe and Cape Colony began to prospect the northern portions of the Transvaal. The miners and prospectors did not, however, exceed a few hundred for several years.

Burgers was able, active, enlightened and impulsive; a visionary rather than a man of affairs or sound judgment He foresaw a great future for the country, but he neglected practical steps to ensure ordered progress, he took up, with all its entanglements, the policy of intrigues with native chiefs beyond the border, and was unable to control the tribes within the border. He held firmly to the belief in having an outlet to the sea free from British control, and in 1875 proceeded to Europe with the project of raising a loan for the construction of a railway to Delagoa bay, though no survey for a railway had been made He was empowered by the *volksraad* to raise £300,000, but with great difficulty he obtained in Holland the sum of £90,000 only, and that at a high rate of interest. With this inadequate sum some railway plant was obtained, which subsequently lay derelict for ten years at Delagoa bay While in Europe, Burgers visited France and Germany, and found in the latter country an awakening interest in South Africa; it was the period of the first stirrings of a colonial policy in Germany. On his return to the Transvaal in 1876 Burgers found that the condition of affairs in the State was worse than ever. The acting-president had in his absence been granted leave by the *volksraad* to carry out various measures opposed to the public welfare, native lands had been indiscriminately allotted to adventurers, and a war with Sikukuni (Secocoeni), a native chief on the eastern borders of the country, was imminent. A commando was called out, which the president himself led The expedition was an ignominious failure, and many burghers did not hesitate to assign their non-success to the fact that Burgers' views on religious questions were not sound Indeed a party of Boers—some 300—had trekked across the Kalahari into Angola largely because they disliked the rule of a heretical *predikant* Burgers then proceeded to levy taxes, which were never paid, and to enrol troops, which never marched The Transvaal was in a bad way, financially it was well-nigh bankrupt.

FIRST ANNEXATION BY GREAT BRITAIN

It was in conditions such as these that the British secretary of State for the colonies, the 4th earl of Carnarvon, launched his scheme for the confederation of the various South African States and colonies The story is told elsewhere (*see* SOUTH AFRICA, UNION OF) In the Transvaal the agent selected to carry out Lord Carnarvon's policy was Sir Theophilus Shepstone (*q v*), the chief of the native affairs department in Natal, a man with a profound knowledge of the mind of the negroes of South East Africa, and also with a considerable knowledge of Boer mentality. He was in London in 1876 and was then given a dormant commission dated Oct 5, 1876, instructing him to visit the Transvaal and empowering him, if it was desired by the inhabitants and in his judgment necessary, to annex the country to the British Crown. Sir Theophilus went to Pretoria in Jan. 1877, with an escort of 25 mounted police, and entered into conferences with the president and executive as to the state of the country. Federation plans were being considered in Cape Colony and Natal and in the Free State; there was also a party in the Transvaal in favour of union. One of the chief difficulties was the different conception of native policy held in the various colonies and States; and the treatment of the natives in the Transvaal caused grave concern to its neighbours The impetus for federation, however, came from without, and the *volksraad*, after having Carnarvon's proposals put before it, rejected them.

When the *volksraad* realized that Shepstone was about to take a decisive step it hurriedly passed a number of reforms, but this

kind of insincere death-bed repentance was useless. On April 12, 1877, Shepstone issued a proclamation annexing the South African Republic to the British Crown. There were protests, some purely formal, others expressing indignation truly felt, but there was no active opposition and a considerable number of the town-dwellers welcomed annexation

Shepstone had given assurances that it was the wish of the British Government that the Transvaal "shall enjoy the fullest legislative privileges compatible with the circumstances of the country and the intelligence of its people." But he did little to substitute anything better for the Government he had found in office, a Government he had characterized as "a thorough sham" Nevertheless he had done something by the abolition of obnoxious taxes while public credit was restored (in the last days of Burgers the Transvaal £1 notes were worth only 1s). Moreover the continuance of the apprentice system—not of the traffic in apprentices—with Shepstone's approval and aid, did not, at least, alienate Boer opinion The true hindrance to acceptance by the Boers of British rule was the failure to redeem the pledge to grant the Transvaal "the fullest legislative privileges" Shepstone at the outset had wanted to summon the *volksraad* (May 1877), but here he met with opposition from the high commissioner, Sir Bartle Frere, who had himself ideas as to what the new constitution should be and wished to consult leading burghers on the matter.

The Agitation for Retrocession.—That the British annexation at first caused no grave discontent may be inferred by the retention of office by all the members of Burgers' executive council except Piet Joubert, "the irreconcilable" The rest, including Paul Kruger and Dr E J P Jorissen (a Hollander brought out by Burgers) kept their posts and drew their salaries as British officials In accordance with a last resolution of the *volksraad,* Kruger, who was accompanied half-heartedly by Jorissen, was given leave to go to London, where he was told by Carnarvon that the act of annexation was irrevocable, but was promised concession in the matter of local government, including the use of Dutch Kruger and Jorissen in turn promised to endeavour to "promote a feeling of satisfaction", showed some anxiety to continue in government employment and after a visit to the Continent returned home This was in Jan 1878, and they found that in the Transvaal the phase of acquiescence in annexation was rapidly passing, for reasons already indicated. Another deputation to London was decided upon, Kruger on this occasion being accompanied by Piet Joubert Before Kruger left Pretoria Shepstone dismissed him from office, holding that it was not the place of an official to be endeavouring to overthrow the Government in whose service he was This deputation spent some months in England (July–Oct 1878) but failed to get satisfaction Carnarvon's federation scheme was moribund and he himself had been succeeded at the Colonial Office by Sir Michael Hicks Beach. Sir Michael told the deputation indeed (despatch of Sept. 16, 1878) that the cabinet intended to grant the Transvaal "to the utmost practical extent its individuality and powers of self-government," but not independence On their way back to the Transvaal Kruger and Joubert met the high commissioner in Natal Frere endorsed Hicks Beach's promise of self-government for the Transvaal, and the Boer leaders (both competent men on the question) gave Frere sound advice in regard to the war with the Zulus then impending. That war began in Jan 1879 and soon there came the disaster of Isandhlwana. Discontent with British rule in the Transvaal was by this time marked; advocates of extreme Dutch Afrikanderdom went so far as to consider it meritorious of the Transvaal burghers to refrain from helping the Zulus against the British.

Shepstone was now replaced by Col. Owen Lanyon, administrator of Griqualand West, an able, active man, but not *persona grata* to the Boers. Then in April 1879 Frere himself visited the Transvaal; and found assembled to meet him on the road to Pretoria an armed commando of recalcitrant Boers who had established a *laager* and looked threatening. Frere induced them to disperse; he set Lanyon to work to effect real reforms. And again he repeated the assurances that the Transvaal would be granted home rule. Just at this time however Frere received news that he had been censured for his Zulu policy by the home Government (the Disraeli cabinet), and he returned to Cape Town. As high commissioner for South-East Africa he was succeeded by Sir Garnet Wolseley. The Zulu War ended, Wolseley in Sept. 1879 came to Pretoria and told the malcontent Boers (by this time the majority of the burghers) in grandiose words that the sun would forget to shine and the Vaal flow backwards sooner than the British flag would cease to fly over the Transvaal. Wolseley gave the country relief in one direction, he reduced to submission (Dec 1879) Sikukuni (Secocoeni), a chief who had long given the Transvaal trouble Instead of granting a liberal constitution he mocked the Boers' hopes by setting up (March 1880) a nominated legislative council In May 1880 Wolseley returned home

Meanwhile events in Great Britain had taken a turn which gave encouragement to the Boers. Gladstone became prime minister and on being directly appealed to by Kruger and Joubert, he replied that the liberty which they sought to manage their own affairs, and which it was the desire of the British Government they should possess, might be "most easily and promptly conceded to the Transvaal as a member of a South African Confederation." That was in June 1880

The Majuba Campaign.—In November matters were brought to a head by the wagons of a farmer named Bezuidenhout being seized in respect of the non-payment of taxes, and promptly retaken from the sheriff by a party of Boers Lanyon began to recognize that the position was becoming grave, and telegraphed to Sir George Colley, the high commissioner of South-East Africa, for military aid This, however, was not immediately available, and on Dec 13 the Boers in public meeting at Paardekraal resolved once more to proclaim the South African Republic, and in the meantime to appoint a triumvirate, consisting of Kruger, Pretorius and Joubert, as a provisional government. Formal proclamation of the republic was made on Dec 16 (Dingaan's Day) at Heidelberg Hostilities forthwith began The first shots fired were outside Potchefstroom, which was then occupied by a small British garrison On Dec. 20, some 240 men under Col. Anstruther, chiefly belonging to the 94th Regiment, while marching from Lydenburg to Pretoria, were surprised at Bronkhorst Spruit, and cut up by the Boer forces Pretoria, Rustenberg, Lydenburg and other smaller towns had been placed in a position of defence under the directions of Col Bellairs Sir George Colley, with 1,400 men, marched towards the Transvaal frontier, but before reaching it he found, on Jan 24, 1881, that the Boers had already invaded Natal and occupied Laing's Nek. He pitched his camp at Ingogo Having been defeated at Laing's Nek, and suffered considerable loss in an engagement near Ingogo, Colley took a force to the top of Majuba, a mountain overlooking the Boer camp and the nek He went up during the night, and in the morning was attacked and overwhelmed by the Boers (Feb 27) Of the 554 men who constituted the British force on Majuba, 92 (including Sir George Colley) were killed and 134 wounded.

For a considerable time before hostilities began efforts had been made in South Africa to adjust the differences between the Transvaalers and the British, notably by President Brand of the O F S. Early in December Brand sent an urgent warning to Cape Town, which reached London only three weeks later and was disregarded. At the opening of parliament on Jan 6, 1881, the queen's speech spoke of the duty of vindicating her majesty's authority; on Jan 26 the first intimation was made—to Cape Town, not to Colley—that the British Government was prepared to negotiate. It was not until the day of the reverse at Ingogo (Feb. 8) that Colley was told of the negotiations Kruger only received the day after Majuba a despatch from Colley of Feb 21, stating that on the Boers ceasing armed opposition, the British Government would be prepared to appoint a commission with large powers Kruger's reply, construed as a virtual acceptance of the British offer, did not reach Sir Evelyn Wood (Colley's successor) until March 7; the previous day a truce had been arranged These negotiations were kept entirely from the knowledge of the British people, who only knew that Sir Frederick Roberts and 10,000 men had been ordered out to South

Africa When they learned that negotiations for peace were proceeding without an attempt to "avenge" Majuba there was great indignation Gladstone insisted that that incident should not be allowed to interrupt negotiations The fact remains that it was only after the British arms had suffered reverses that the British cabinet opened negotiations Alike by the Boers and by the "loyalists" in South Africa the peace shortly afterwards concluded was regarded as a British surrender. The bitterness felt by the British over their "betrayal" was intense, so intense that it turned to hatred in many cases Nor would it be easy to exaggerate the feeling of disgust felt by the Natalians over Gladstone's action. Nevertheless in view of the "loitering unwisdom" shown by the British almost from the day of annexation the retrocession of the Transvaal was the proper end of the episode

A convention signed at Pretoria on Aug 3, 1881, regulated the new relations between the Transvaal and the British Government The Boers were granted internal self-government, but British suzerainty was explicitly maintained, a British Resident was appointed to Pretoria; the country was to be called the Transvaal State, the frontiers (for the first time) were defined In drawing up the convention Wood had as colleagues Sir Hercules Robinson (the new high commissioner) and Chief Justice de Villiers, of the Cape bench, an Afrikander who, like President Brand, had done much to keep in check Dutch feeling in South Africa generally The government of the Transvaal was handed over to the Boer triumvirate on Aug 8; it was continued in their name until May 1883 when Kruger was elected president—an office he held until the Transvaal again lost its independence

FROM RETROCESSION TO THE SOUTH AFRICAN WAR

The Transvaal in 1881 was in a much better condition than in 1877, in material matters the retrocession conditions much favoured the Boers And a new commercial era was dawning But the burghers were dissatisfied with the limitations of the Pretoria Convention; nor did they keep its terms Especially they encroached once again on Bechuanaland, where they set up the so-styled republics of Stellaland and Goshen Kruger, in reply to remonstrances, described this as an "irresponsible" movement for expansion, came again to London (Nov 1883) and with the 15th earl of Derby, then secretary of State for the colonies, concluded another agreement known as the London Convention It was signed on Feb 27, 1884, being the third anniversary of the fight at Majuba The London Convention neither denied nor affirmed British suzerainty—Lord Derby maintained that he had preserved the substance if not the word—but limits were still imposed on complete independence The State was permitted again to call itself the South African Republic; but it bound itself not to extend its borders, which were once again strictly defined, to allow freedom of trade, travel and residence to "all persons" other than natives, not to impose any taxes, local or general, upon foreigners other than those imposed on citizens of the republic (this to apply to the persons, property, commerce and industry of such foreigners) and to conclude no treaty or engagement with any other State or nation (the Orange Free State excepted) nor with any native tribe east or west of the republic until such treaty had been approved by the British Government

Territorial Expansion.—Notwithstanding the precise fixing of the boundaries of the republic by the London Convention, Kruger endeavoured to maintain the Boer hold on Goshen and Stellaland, but the British Government on this point proved firm, and an expedition set out in 1884 under Sir Charles Warren, broke up the freebooters' two states, and occupied the country without a shot being fired (*see* BECHUANALAND) This at last put an end to Boer attempts at encroachment westwards, and a little later treaties with Lobengula and the grant to Cecil Rhodes and his co-directors of a charter for the British South Africa Company put a check on designs the Boers held to expand northwards (*see* RHODESIA).

On the eastern border the policy of expansion was also followed by the Boers, and in this instance with more success Following the downfall of the Zulu power after the British conquest in 1879, several parties of Boers began intriguing with the petty chiefs, and in May 1884, in the presence of 10,000 Zulus, they proclaimed Dinizulu, the son of Cetywayo, to be king of Zululand (*see* ZULULAND) As a "reward" for their services to the Zulus, the Boers, under Gen Lukas Meyer, then took over from them a tract of country in which they established a "New Republic" In 1886 the "New Republic," with limits considerably narrowed, was recognized by Great Britain, and the territory became incorporated with the Transvaal in 1888 A similar policy eventually brought Swaziland almost entirely under their dominion (*see* SWAZILAND) At the same time Kruger revived the project of obtaining a seaport for the State, one of the objects of Boer ambitions since 1860 (vide *supra*) Kruger endeavoured to acquire Kosi bay, to the north of Zululand and only 50m east of the Swazi frontier In this endeavour he was foiled, for the British annexed Tongoland and with it Kosi bay, but that was not until 1895

Gold Discoveries: Influx of Uitlanders.—In 1884, the year of the London Convention, the Sheba gold mine in the de Kaap valley—where gold had been found as far back as 1875—had attracted a population of about 1,000 For the first time gold digging in the Transvaal ceased to be a precarious method of earning an existence Barberton was founded, there was a rush to the fields from Europe as well as South Africa Soon, however, came collapse, by the end of 1887 the Barberton fields were mostly deserted In the meantime, gold had been discovered on the Witwatersrand The gold fields there were proclaimed and Johannesburg founded at the end of 1886 In a very few years it was seen that here was the richest gold field in the world, and a republic composed mainly of cattle and sheep farmers of very limited outlook and education was speedily faced with a difficult problem Thousands of whites poured into the Transvaal so that in a few years the *uitlanders* came to outnumber the native white population The newcomers included a large proportion of South Africans, both Dutch and English speaking, from the Cape, Natal and the Free State; equally with Europeans and Americans they were regarded as *uitlanders* This new population was concentrated in one region—the Rand

President Kruger and the *raad* had two points to consider (1) economic, (2) political The Boers gained by the development of mining, both individually and as a State Land went up enormously in value; so attractive were the prices realized that a third or more of the area of the country was sold to *uitlanders* But with speculation and wealth came also corruption and peculation, vices to which many members of the Boer executive succumbed But the Boer was shrewd and at once grasped the need of railway transport from the mines to the sea From their first crossing of the Vaal the Boers had sought an outlet at Delagoa bay—its great attraction being that it was not under British control Alternatively, or additionally, they had sought a seaport of their own—hence the effort to secure Kosi bay In 1884 Kruger granted a concession to Hollander and German capitalists of all rights to build railways in the Transvaal, this led to the formation of the Netherlands South African Railway Company The grant of monopolies, as an easy way of raising revenue, had become a feature of Transvaal methods from the time of the retrocession in 1881 In 1882 a monopoly was granted for the manufacture of spirituous liquor. By 1889 the list of things under monopoly grants, besides railways and spirits, included dynamite, iron, sugar, wool, bricks, jam and paper The dynamite monopoly, a necessity for the mines, pressed particularly heavily on the gold industry.

The political policy of the Boers was animated by a lively distrust of everything British With many of his people Kruger came also to distrust the Cape Dutch, whose interests suffered with those of other *uitlanders,* from the policy of rigid exclusion of the newcomers from political power in the Transvaal. In 1882 a law had been passed raising the period of residence necessary to obtain full franchise rights from two to five years—a reasonable requirement; but the Boers soon foresaw that before long under that law many *uitlanders* would qualify for the franchise Other measures, then, must be tried to maintain Boer supremacy. In 1887 Kruger endeavoured to induce the Orange

Free State to enter into an offensive and defensive alliance with the Transvaal against the "common enemy" President Brand, who did not see an enemy in Great Britain, refused. but in 1889 Kruger got his treaty with the new president of the O F S—F. W. Reitz. Next came, in 1890, a raising of the franchise qualification, followed in 1894 by other laws, the effect being that no foreigner under 40 could obtain the franchise, and then only if he had lived 14 years in the Transvaal. Kruger's object was the preservation of the independence of the country; that is the maintenance in full power of the Boer burghers, his distrust of the British had led him to open relations with Germany, which country, with her colonial fever then at the full, responded at once, but with a natural regard to German rather than Boer interests

The mining industry on the Rand had grown very rapidly. At first there was the usual rush and struggle on the gold fields, but in four or five years, while there was the inevitable gathering of undesirables and of those who never intended to settle, there was too a settled community—mainly British—decent and hard working, and capable of voicing its grievances The feeling entertained towards the president was shown in an unfortunate incident when he visited Johannesburg in 1890 The Transvaal flag flying over the *landdrost's* house was pulled down by the mob Kruger was greatly incensed, and for years he quoted it as a reason against granting *uitlander* claims

First Reform Movement.—Representations made to the Government at Pretoria in the year 1890 were unavailing, and by 1892 the *uitlanders* felt that to obtain redress both for their political and economic grievances they must resort to combined action. What became known as the first reform movement was then started The Transvaal National Union was formed by mercantile and professional men and artisans The chairman was J Tudhope, an ex-minister of Cape Colony, and its most prominent members Charles Leonard and his brother James Leonard, ex-attorney-general of Cape Colony Both the Leonards, as well as many of their followers, were South Africans by birth They, in common with the great bulk of the *uitlanders,* recognized that the State had every right to have its independence respected But they asserted that a narrow and retrogressive policy, such as Kruger was following, was the very thing to endanger that independence The legitimacy of *uitlander* aspirations were recognized by a few Boer officials at Pretoria But Kruger, in reply to seven delegates from the National Union, in Sept 1892, told Charles Leonard to "go back and tell your people that I shall never give them anything I shall never change my policy And now let the storm burst"

In 1894 British subjects in the Transvaal were commandeered to suppress a native rising This brought a sharp and effective remonstrance from the high commissioner, Sir Henry Loch, who came up to the Transvaal, his visit to the Rand being made the occasion of a "jingo" demonstration highly offensive to the Boers and insulting to the president Then at a banquet in Jan 1895 in honour of the German emperor's birthday Kruger referred in glowing terms to the friendship of Germany for the Transvaal, in May 1895 the Boer road to the sea was finally blocked by the proclamation of a British protectorate over Tongoland (which included Kosi bay) The Transvaal Government had failed to fulfil the conditions under which it might have secured Kosi bay, the definite loss of the port made the Boers angry. The really remarkable thing was that Great Britain should for so long have left open to Boer or German adventurers so tempting a harbourage.

Railway politics played their part in the drama. The goal of the railways was the Rand and it was Kruger's policy to favour Delagoa bay. Nevertheless until the railways were complete the Natalians with their ox-transport service got most of the trade. But there was much delay in building the Portuguese section of the Delagoa line and through-rail connection between the Rand and the Cape ports came first (Sept. 1892) However, less than two years later—in May 1894—the Netherlands Railway Company (of which the Transvaal Government took 85% of the profits) had at last connected the Rand with Delagoa bay Efforts made by the Cape Government to keep a fair share of the traffic failed, and to encourage trade to Delagoa bay prohibitive rates were imposed on the 30m. of the line to Cape ports within the Transvaal The Cape retaliated by unloading goods at certain drifts (fords) over the Vaal and sending them on thence by wagon to Johannesburg This was in Sept. 1895; in October, Kruger closed the drifts The Cape Government appealed to the British Government, and under an almost direct threat of war the Transvaal gave way and the drifts were reopened in Nov 1895 Kruger had broken the London Convention in closing the drifts and knew he was in the wrong While this dispute was still unsettled the railway from Durban reached the Rand Natal, it had been agreed, was to get a third of the Rand traffic

At this time—1895—the *uitlanders,* according to a well informed member of that community, owned half the land and nine-tenths of the property of the country, a statement which partly explains Kruger's determination to prevent the "stifling" of Boer nationality which he held would follow the grant of the franchise to the *uitlander* But there were many burghers who held enlightened views and who saw that the admission of *uitlanders* to the franchise—many taking up citizenship would have been South Africans—would in reality preserve the republic These men had chosen Piet Joubert as reform candidate for the presidency in the election which occurred in 1893 All the liberal elements in the Transvaal supported Joubert, the official figures (not, it is believed, the true figures) gave Kruger a majority of 700 out of some 15,000 burghers voting Kruger ignored protests and retained office Henceforth he kept power, aided by the Hollander advisers he had gathered round him, of whom Dr W J Leyds, State secretary, was the most prominent By 1895 the great majority of the *uitlanders,* who had neither the wealth of the mine owners nor any civic rights, were growing desperate Many felt that, as Kruger expected, "the storm would burst"

(F. R C)

The Jameson Raid.—At this juncture (Oct 1895) came overtures to the leading *uitlanders* from Cecil Rhodes, then prime minister of Cape Colony, and from Dr Jameson, leading to the Jameson Raid. To one or two men this scheme, subsequently known as the Jameson Plan, had been revealed in the previous June, but to the majority even of the small group of leaders it was not known till Oct or Nov 1895 The proposition came in a tempting hour Between them it was arranged that Jameson should gather a force of 800 men on the Transvaal border, that the *uitlanders* should continue their agitation; and that, should no satisfactory concession be obtained from Kruger, a combined movement of armed forces should be made against the Government The arsenal at Pretoria was to be seized, the *uitlanders* in Johannesburg were to rise and hold the town Jameson was to make a rapid march to Johannesburg Meanwhile, in order to give Kruger a final chance of making concessions with a good grace, and for the purpose of stating the *uitlander* case to the world, Charles Leonard, as chairman of the National Union, issued a manifesto, which concluded as follows —

> What do we want? We want (1) the establishment of this republic as a true republic, (2) a *grondwet* or constitution which shall be framed by competent persons selected by representatives of the whole people and framed on lines laid down by them—a constitution which shall be safeguarded against hasty alteration, (3) an equitable franchise law and fair representation, (4) equality of the Dutch and English languages, (5) responsibility of the legislature to the heads of the great departments, (6) removal of religious disabilities, (7) independence of the courts of justice, with adequate and secured remuneration of the judges, (8) liberal and comprehensive education, (9) efficient civil service, with adequate provision for pay and pension, (10) free trade in South African products That is what we want

The Jameson conspiracy fared no worse and no better than the great majority of conspiracies in history Jameson did not obtain more than 500 men Johannesburg had the greatest difficulty in smuggling in and distributing the rifles with which the insurgents were to be armed. The scheme to seize the Pretoria fort had to be abandoned, as at the time fixed Pretoria was thronged with Boers Finally, Jameson, becoming impatient of delay, in spite of receiving direct messages from the leaders at

Johannesburg telling him on no account to move, marched into the Transvaal.

The policy of delay in the execution of the plot which the *uitlander* leaders found themselves compelled to adopt was determined by a variety of causes. Apart from the difficulty of obtaining arms, a serious question arose at the eleventh hour which filled some of the *uitlanders* with mistrust The reform leaders in the Transvaal, down to and including the Johannesburg rising, had always recognized as a cardinal principle the maintenance of the independence of the State From Cape Town it was now hinted that the movement in which Jameson was to co-operate should, in Rhodes's view, be carried out under the British flag. A meeting of *uitlander* leaders was hastily summoned on Dec. 25 Two messengers were that night despatched to interview Rhodes, who then gave the assurance that the flag question might be left to a plebiscite of the inhabitants of the Transvaal (see *Blue-book,* 1897, 165, p 21) It was determined nevertheless to postpone action; however, on Dec 29, Jameson started, and the news of his having done so reached Johannesburg from outside sources. A number of leading citizens were at once formed into a reform committee In the absence of Charles Leonard, who had been sent as one of the delegates to Cape Town to interview Rhodes, Lionel Phillips, a partner in Messrs. Eckstein and Company, the largest mining firm on the Rand, was elected chairman Under the supervision of the reform committee, such arms as had been smuggled in were distributed, and Col Frank Rhodes was given charge of the armed men A large body of police was enrolled, and order was maintained throughout the town On Jan 2, 1896, Jameson, who found himself at Doornkop in a position surrounded by Boers, surrendered Jameson and his men were conveyed to Pretoria as prisoners, and subsequently handed over to the high commissioner (Sir Hercules Robinson, who had succeeded Sir Henry Loch in June 1895)

Years later, speaking at Durban (Aug 9, 1910), Jameson declared that the raid was not racial in the sense usually understood, but an effort towards federation Had the raid succeeded it was proposed to make Gen Lukas Meyer (d. 1902) president. He subsequently explained, however, that they had had no communication with Meyer on the subject.

The Kaiser's Telegram.—Significant of the attitude of Germany—whose "flirtation" with the Transvaal has been noted—was an open telegram sent by the emperor William II the day after the surrender of Jameson, congratulating Kruger that "without appealing to the help of friendly Powers" he had repelled the raiders. The British Government rejoined by commissioning a flying squadron and by calling attention to the London Convention In Johannesburg meanwhile the Kruger government regained control The members of the reform committee (except a few who fled the country) were arrested on a charge of high treason and imprisoned in Pretoria In April, at the trial, the four leaders—Lionel Phillips, Frank Rhodes, J H. Hammond and George Farrar, who in conjunction with Charles Leonard had made the arrangements with Jameson—were sentenced to death, the sentence being after some months' imprisonment commuted to a fine of £25,000 each. The rest of the committee were each sentenced to two years' imprisonment, £2,000 fine or another year's imprisonment and three years' banishment This sentence, after a month's incarceration, was also commuted The fine was exacted, and the prisoners, with the exception of Woolls Sampson and W D (Karri) Davies, were liberated on undertaking to abstain from politics for three years in lieu of banishment Sampson and Davies, refusing to appeal to the executive for a reconsideration of their sentence, were retained in prison for over a year

After the Raid.—Hercules Robinson reached Pretoria on Jan 4 He had no sooner learnt of the raid in Cape Town than he issued a proclamation through Sir Jacobus de Wet, the British resident at Pretoria, warning all British subjects in Johannesburg or elsewhere from aiding and abetting Jameson. This was freely distributed among the public of Johannesburg While in Pretoria the high commissioner in the first instance addressed himself to inducing Johannesburg to lay down its arms He telegraphed to the reform committee that Kruger had insisted "that Johannesburg must lay down arms unconditionally as a precedent to any discussions and consideration of grievances." On the following day, Jan. 7, Sir Hercules telegraphed again through the British agent, who was then at Johannesburg, saying that "if the *uitlanders* do not comply with my request they will forfeit all claims to sympathy from Her Majesty's Government and from British subjects throughout the world, as the lives of Jameson and the prisoners are now practically in their hands." The 2,000 odd rifles which had been distributed among the *uitlanders* were then given up. After the Johannesburg disarmament Kruger had 64 members of the reform committee arrested, announcing at the same time that his motto would be "Forget and forgive" In 1897 Hercules Robinson was succeeded in the high commissionership by Alfred (Lord) Milner.

In the period which intervened between the Jameson raid and the outbreak of the war in Oct. 1899 President Kruger's administration deteriorated The Aliens Expulsion and Immigration Laws, as well as the new Press Law, were passed in the latter part of 1896. In 1897 a decision of Chief Justice Kotze was overruled by an act of the *volksraad* This led to a strong protest from the judges of the high court, and eventually to the dismissal of the chief justice, who had held that office for over 20 years, and had shown himself an able and upright judge An industrial commission appointed during this year by President Kruger fared no better than the high court had done It made several sensible proposals which would have helped both the mining industry and the administration, but to very little purpose All remonstrances, all warnings from the Dutch-speaking people of the Cape were unheeded

Second Reform Movement.—In March 1899 the *uitlanders*, hopeless of ever obtaining redress from President Kruger, weary of sending petitions to the *raad* only to be jeered at, determined to invoke intervention if nothing else could avail, and forwarded a petition to Queen Victoria This petition, the outcome of the second *uitlander* movement for reform, was signed by 21,000 British subjects, and stated the *uitlander* position

In response to this appeal, Chamberlain, in a despatch dated May 10, proposed a conference at Pretoria Six days before Sir Alfred Milner had telegraphed to London a summary of the situation, comparing the position of the *uitlanders* to that of helots and declaring the case for intervention to be overwhelming Neither of these despatches was made public at the time But on the day Chamberlain wrote his despatch the friends of the Transvaal Government in Cape Colony and the Orange Free State invited Milner to meet Kruger at Bloemfontein, hoping to be able to exert pressure on both parties and to arrange a settlement as favourable as possible to the Transvaal. The conference opened on May 31 and closed on June 5 It no sooner opened than it was evident that Kruger had come to obtain, not to grant, concessions. He offered, it is true, a seven years' franchise law in place of the five years' franchise which Sir Alfred Milner asked for. But this seven years' franchise was only to be given on certain conditions, one of which was that all future disputes between the Transvaal and the Imperial Government should be referred to a court of arbitration, the president of which should be a foreigner. Milner urged the home Government to insist upon a minimum of reform, and primarily on the five years' franchise (this had the full support of the *uitlanders* and of the majority of whites throughout South Africa); and Chamberlain, backed by the cabinet, adopted the policy of the high commissioner.

(X)

The Eve of War.—Each side had committed itself to a position from which a peaceful issue was unlikely The most stupid explanation of the impasse is that which attributes the forcing of the hands of the British Government to Rand "magnates" who desired to seize the gold fields. It is more true to say the quarrel was racial; it is certain that Kruger and his advisers fully understood that the grant of political rights to the *uitlanders* meant the doom of their rule; and they vastly underrated the military power of Great Britain.

After the Bloemfontein Conference the tactics of the Boer executive were simply directed towards putting off a crisis till the

beginning of October, when the grass would be growing on the veld, and meanwhile towards doing all they could in their despatches to put the blame on Great Britain. At last they drafted, on Sept. 27, an ultimatum to the British Government. For military rather than diplomatic reasons it was not until Oct. 9 that the ultimatum was presented to Conyngham Greene, the British agent at Pretoria. The scheduled demands were —

"(*a*) That all points of mutual difference shall be regulated by the friendly course of arbitration, or by whatever amicable way may be agreed upon by the Government with Her Majesty's Government. (*b*) That the troops on the borders of this republic shall be instantly withdrawn (*c*) That all reinforcements of troops which have arrived in South Africa since June 1, 1899, shall be removed from South Africa within a reasonable time, to be agreed upon with this Government, and with a mutual assurance and guarantee on the part of this Government that no attack upon or hostilities against any portion of the possessions of the British Government shall be made by the republic during further negotiations within a period of time to be subsequently agreed upon between the Governments, and this Government will, on compliance therewith, be prepared to withdraw the armed burghers of this republic from the borders. (*d*) That Her Majesty's troops now on the high seas shall not be landed in any part of South Africa" To these demands the Transvaal Government required an answer within 48 hours

There could be only one reply, and on Wednesday, Oct 11, 1899, at five o'clock P M, a state of war existed between the British Government and the two Boer republics, for the Free State threw in its lot with the Transvaal

FROM ANNEXATION TO UNION: AND AFTER

The course of the war is described in detail in the article SOUTH AFRICAN WAR On July 4, 1900, a month after the occupation of Pretoria, a commission was issued to Lord Roberts authorizing him to annex the Transvaal. The proclamation of annexation was dated Sept 1. Lord Roberts held the post of administrator of the colony until his departure for England in the December following, when he was succeeded by Milner, the high commissioner It was not, however, until March 1901 that Milner, who resigned his governorship of Cape Colony, arrived at Pretoria to inaugurate a civil administration Hostilities were still proceeding, but in the areas under control Lord Milner (who was raised to the peerage in May) speedily set the machinery of government in motion.

Reconstruction.—Some of the gold mines were permitted to restart crushing in May 1901 In November following the main body of the *uitlanders* were allowed to return to the Rand and in June 1902 a tax of 10% on the profits of gold mining was imposed The administration was equally alive to the needs of the country districts and a land board was established in Dec 1901 Another department taken in hand was that of education; and here remarkable success was achieved

After the signature of the articles of peace the work of reconstruction was accelerated The end of the military government was signalled by the assumption, June 21, 1902, by Lord Milner of the title of governor of the Transvaal and by the creation of an executive council With the proceeds of a loan of £35,000,000, guaranteed by the British Government, the debt of the South African Republic was paid off, the Transvaal and the Orange River Colony railways were bought by the State, and new railways and other public works were undertaken. The £3,000,000 granted by the articles of peace, and other considerable sums, besides £7,000,000 from the loan, were expended on repatriation and compensation.

The efforts made by the administration to restore the Boers to the land, to develop the material resources of the country, and to remove all barriers to the intellectual and moral development of the people, were soon, however, hampered by severe commercial depression.

Chinese Labour.—The commercial depression was due to many causes; of these the most apparent was the shortage of labour at the Rand mines. When work restarted after the war, the mine owners offered the native workmen little more than half the wages paid in 1898, but this effort at economy was abandoned, and the old rates of pay were restored in Jan 1903 Nevertheless, the labour available continued to be very much below the needs of the mines The consequent small gold output meant a serious decrease of revenue, which was not compensated for by the heavy tax levied on the output of the Premier diamond mine, where operations began in 1903 Finally, to enable them to work their mines to their full capacity, the Rand houses asked for leave to import Chinese labourers. Milner, anxious above everything else to obtain sufficient revenue to carry on his work of reconstruction, gave his consent to the experiment The home Government concurred, and during 1904–06 over 50,000 Chinese were brought to the Rand on three years' indentures In the Transvaal all parties agreed that no new racial or economic complications should be permitted. and these were guarded against by the restriction of the coolies to unskilled labour in the gold mines and by their compulsory repatriation By the introduction of the Chinese the gold output from the mines was greatly increased, with the result that the Transvaal suffered less than any other part of South Africa from the restriction of commerce, which lasted for several years.

The discussions in the legislative council on the Chinese coolie question had been accompanied by a demand on the part of the Boers that such an important step should not be taken "without the constitutional approval of the white people of the Transvaal", and after the importation of the coolies had begun, the agitation for the grant of representative institutions grew in volume. The British Government was also of opinion that the time was near for the setting up of such institutions, and the pending grant of a constitution to the Transvaal was announced in parliament in July 1904. Meantime the existing (nominated) legislative council was dealing with another and a vital phase of the Asiatic question There were in the Transvaal some 10,000 British Indians, whose right to "enter, travel or reside" in the country was secured by the London Convention of 1884 Under republican rule these Indians—who were mainly small shopkeepers, but included some professional men of high standing—had suffered many restrictions, and their cause had been espoused by the British Government. Nevertheless, under British rule their situation was in no way improved, and a determination was shown by the European inhabitants of the Transvaal, both British and Boer, further to restrict their privileges and at the same time to stop the immigration of other Indians Alfred Lyttelton (who had succeeded Chamberlain as secretary of State for the colonies) endeavoured to meet the wishes of the Transvaal by sanctioning legislation which would greatly restrict the immigration of Indians, but he would allow no tampering with the rights of Indians already in the colony

Self-government.—A constitution for the Transvaal on representative lines was promulgated by letters patent on March 31, 1905; but there was already an agitation for the immediate grant of full self-government, and on the accession to office of the Campbell-Bannerman administration in Dec 1905 it was decided to accede to it New letters patent were issued (Dec 12, 1906), and the first general election (Feb 1907) resulted in the return of a majority belonging to *Het Volk*, a Boer organization formed for political purposes. Lord Selborne, who had during 1905 succeeded Lord Milner as high commissioner and governor of the Transvaal, entrusted Gen Botha with the formation of a ministry. Botha chose as colleagues Gen. J C. Smuts and other men of progressive, in some respects democratic, views, and thus showed his determination not to be dominated by the "back veld" Boers He was strengthened in his attitude by the firm action of the Progressive (*i.e.*, the ex-*Uitlander*) Party, which secured 21 seats (out of a total of 69) in the legislative chamber, entirely in the Rand and Pretoria districts, and was led by Sir George Farrar and Sir Percy Fitzpatrick The Government announced that there would be no wholesale repatriation of Chinese The men left gradually as the licences expired, and by Feb 1910 all the Chinese coolies had returned home. At the same time successful efforts were made by the ministry to increase the supply of native labour

for the mines On the education question an agreement satisfactory to both the British and Dutch-speaking communities was reached.

One of the first problems which confronted the Botha ministry was the attitude to be adopted towards the other British colonies in South Africa. Milner, by various measures, had endeavoured to pave the way for federation, and Chamberlain when he visited South Africa in 1903 had also put forward federation as the desired goal On economic as well as political grounds, the leaders of both parties in the Transvaal were prepared to consider favourably the proposals put forward by Dr. Jameson at the close of 1906 for a closer union of all the self-governing colonies, and the first direct step to that end was taken at an inter-colonial conference held in May 1908. The history of this movement, which resulted in the establishment of the Union of South Africa on May 31, 1910, is given under SOUTH AFRICA, UNION OF. Apart from this movement the most notable events in the Transvaal at this period were the development of agriculture, the gradual revival of trade (the output of the gold mines in 1909 totalled £30,925,000, and at the end of the year 156,000 native labourers were employed), and the continued difficulty with regard to British Indians On this last point the Botha ministry sought to enforce registration of Indians, and, for failing to register, M V Gandhi and other leaders were imprisoned in 1908 and large numbers of Indians were deported However, the establishment of the Union of South Africa removed from the competence of the Transvaal provincial council all legislation specially or differentially affecting Asiatics.

The Union.—When the Union was established Gen Botha became prime minister, two of his colleagues, Smuts and Hull, also joining the Union ministry A fourth minister—Johann F. B Rissik—was appointed first administrator of the Transvaal province, a post he held until 1917, when A G Robertson succeeded, and remained administrator till 1924 Much of the energy of the provincial council was given to education, in which many bold experiments were made

A considerable number of Boers in the western Transvaal took part in the rebellion of 1914, but the influence of Gens Botha and Smuts kept most burghers loyal to the British connection The disturbances on the Rand in 1913–14 and the revolt of 1922 were not on racial lines, though the majority of the white miners had by this time become Dutch-speaking But feelings were strongly marked in the provincial council, as was shown by agitations against officials because of their nationality or their politics Thus, after the general election in June 1924, when the Nationalist and Labour parties gained the victory, there was an agitation to remove the newly appointed administrator, J. H Hofmeyr, because he belonged to the South African party, an agitation which Gen Hertzog, the prime minister, refused to heed In the flag controversy of 1926–27 the Dutch burghers followed Tielman Roos, then minister of justice and leader of the Transvaal Nationalists, who supported the compromise by which both the Vierkleur and the union jack formed part of the flag. Both political and economic questions had however largely ceased to be kept within provincial lines.

The respective claims of Durban and Lourenço Marques (Delagoa bay) to the trade of the Rand had been settled in 1909 by an agreement, known as the Mozambique Convention, signed by the Transvaal and Portuguese authorities This convention also permitted the recruitment of Portuguese natives for work in the Transvaal mines Difficulties arose and the convention lapsed in 1923 though a *modus vivendi* was reached in respect of native labour. In the negotiations for a new solution the question of the control of Lourenço Marques gave much trouble Eventually on Sept. 11, 1928, a new convention was concluded at Pretoria between the Union Government and the Portuguese.

TRANSVERSE RIB or CROSS RIB, in architecture. (*See* VAULT)

TRANSYLVANIA, a former principality (*Grossfürstentum*) occupying, until 1918, the extreme eastern portion of the kingdom of Hungary, but then added to Rumania, since when the Rumanian name Ardeal has become the official one. It has an area of 22,312 sq m and a population of 2,678,367.

Transylvania has the form of an irregular circle, and is a high plateau of a mean altitude of 1,000–1,600 ft above sea-level, surrounded on all sides by the Transylvanian mountains (*q v*), the south-eastern continuation of the Carpathian system On the west side there are easy passes, but on the east and south frontiers the lofty mountains give Transylvania the aspect of a huge natural fortress.

The Latin name appears first after the 12th century, and signifies "beyond the woods," *i e*, from Hungary; the Hungarian and Rumanian names both mean "forest land ' The German name is usually derived from the seven principal fortified towns or "burgs," founded by the German colonists, though some authorities prefer to connect it with the Cibin mountains on the south frontier Until 1848 political rights belonged only to the Hungarian and the closely-related Szekler and the Saxon inhabitants, the Rumanian majority having no recognition These privileged elements formed rather more than 40% of the population, the Hungarians being Roman Catholics or Unitarians and the Germans Protestants. A gipsy element has long been important The chief town is Cluj (Kolozsvár). (For further geographical details *see* RUMANIA and TRANSYLVANIAN MOUNTAINS) (H J. F.)

HISTORY

After A D. 103 Transylvania formed part of the Roman province of Dacia (*q.v.*), and long supported a large Roman or Romanized population. After Aurelian withdrew his legions (A D 271) its history remains a blank for many centuries It was occupied or overrun by various Germanic (Goths, Gepidae), Ural-Altaic (Huns, Avars, perhaps Bulgars, Petchenegs), and probably also Slavonic tribes The debated question whether a Roman population survived these storms is discussed elsewhere (*see* VLACHS) The very few early documents on Transylvania mention Vlachs first in 1222, and then as shepherds; but they appear soon after as settled peasants; Vlach "nobles" are specifically mentioned in the 13th and 14th centuries, after which they apparently became Magyarized, and at this period the Vlach population in Transylvania, the Banat and Maramures, was certainly considerable and increasing.

Hungarian Conquest.—In 1003 King Stephen of Hungary incorporated Transylvania in his domains under a voivode, also granting fiefs to certain nobles. The early Hungarian administration was probably somewhat shadowy, but it was consolidated at an early date by settlements of the Széklers (*q.v.*) in the south-east, probably as a frontier guard, and of the "Saxons" (Germans from Luxembourg and the Rhine) for the same purpose in the 12th and 13th centuries Both Saxons and Széklers were free, self-governing communities under the king The Saxons especially, who founded numerous cities, were a great civilizing influence. The chief of their many privileges was the charter granted them in 1224 by Andrew II. As organized in the 14th century, they formed the communities of the "Sieben Stuhle" round Hermannstadt (Sibiu), the "Zwei Stühle" (Medias), the Burzenland (Kronstadt, Rum. Brassó), and the Nösnerland (Bistritz, Rum. Bistrita)

In spite of various invasions, the chief being the Mongol of 1241, the early prosperity of Transylvania was considerable and its communal life active. Its diet met at least as early as 1222:

and when the power of Hungary began to decline, and Turkish invasions harassed the frontiers, the dominant classes took steps to defend their own position A rising of the Magyar and Vlach peasants in 1437 caused the Saxons, Széklers, and nobles to meet at Kápolna on Sept. 14 of that year and conclude a "Brotherly Union," by which they swore fealty to the king of Hungary, promised to support each other against the peasants and the Turks, and agreed to settle disputes between themselves by arbitration. This union was renewed in 1438 and 1459, and in 1506 a supreme court of justice was established for all three communities, then referred to as "nations" This third union formed henceforward the basis of the Transylvanian local constitution, relations with the serfs being regulated by the "codex tripartitum" introduced in Hungary in 1515, after the peasant rising of the previous year

Transylvania a Principality.—After the defeat of the Hungarian forces by the Turks at Mohács (1526), John Zápolya, voivode of Transylvania, who had arrived too late for the battle, was left the strongest power in Hungary and elected king by the anti-Hapsburg party (Nov. 10, 1526) He was recognized as king of Transylvania and part of Hungary by Ferdinand I. of Austria (1538); and on his death in 1540 the Estates, instead of joining Austria, as had been stipulated, elected Zápolya's son, cut themselves loose from Hungary, and became tributary to the sultan Under the dynasties of Zápolya and Báthory the princes of Transylvania were able to preserve practical independence by playing off the sultan against the emperor, and to play an important part in international affairs, especially under Stephen Báthory (1576–86), who was also king of Poland.

The chief internal event of the 16th century was the triumph, after a severe struggle, of the Reformation The Saxons were converted to the Lutheran Church, the majority of the Magyars to the Calvinist, and another party, including most of the Széklers, to the Unitarian A certain party, usually identified with the Hapsburg cause, remained Catholic The diet, by a series of resolutions (1557, 1568, 1571, Compilation of 1669), declared the Calvinist, Catholic, Lutheran, and Unitarian religions to be alone "received" and entitled to free exercise and equal rights for all time By this means it bound another shackle on the Rumanian peasantry, who were Greek Orthodox and controlled by a patriarch in Wallachia. The backbone of the national movement was formed by the various Protestant creeds, and the efforts of the Catholic Báthorys, assisted by the Jesuits, to carry through the Counter-Reformation were a main cause of the confused wars which filled the last years of the century, in the course of which a fourth party in the person of Michael, voivode of Wallachia (1593–1601), unexpectedly intervened and for a year (1600) actually united Moldavia, Wallachia, and Transylvania in a national Rumanian state, for which, however, he did homage to the emperor He was murdered in 1601 by order of General Basta, and in 1604 the emperor Rudolph secured Transylvania; but the persecutions indulged in by the imperial troops under General Basta, and the proselytizing fury of the Jesuits, provoked a speedy rebellion On April 5, 1605, the diet elected as prince Stephen Bocskai (*q v.*), who, by the Peace of Vienna (June 23, 1606), forced the emperor to recognize him as prince of an enlarged Transylvania and secured the confirmation of all traditional liberties; while by the Truce of Zsitvatorok (Nov. 1606) he negotiated a 20 years' truce between the emperor and the sultan. Unfortunately, Bocskai died on Dec 29, 1606 Gabriel Báthory (1608–13) was the most tyrannical ruler Transylvania ever had; but the reign of Gabriel Bethlen (1613–29) restored the principality's former glories and is generally regarded as its golden age.

Under Bethlen and George Rákóczy I. (1631–48) Transylvania was again a power of international importance and the chief bulwark of Protestantism in Eastern Europe The emperor, distracted by the Thirty Years' War, was obliged to treat with the princes of Transylvania as equals, while the Turkish empire, for the time, was unable to interfere with its nominal vassal. Only when George Rákóczy II. (1648–57) was defeated in an unlucky campaign against Poland did the reviving Porte again intervene, depose Rákóczy, and, after six princes had died violent deaths within three years, appoint a Székler, Michael Apafi (1661), who ruled as a mere vassal of the Turks, and Transylvania sank again into extreme misery

When the Turks were defeated before Vienna (1683), and their power again declined, the Estates opened secret negotiations with the emperor Leopold I, whose suzerainty they recognized under the Treaties of Vienna (1686) and Blasendorf (Blaj) (1687) Apafi died in 1690, being succeeded by his son, Apafi II. On Dec 4, 1691, the emperor Leopold, after long negotiations, issued the diploma which regulated relations between him and his subjects

Period of Hapsburg Rule.—By this most important document the emperor swore to uphold the constitution of Transylvania, which was again considered *de jure* a part of Hungary, confirmed the privileges and liberties of the three "nations" and four "received religions," and agreed that the diet should meet annually, but also imposed a tribute on Transylvania, stationed a garrison in it, and put it under a "gubernium," directed after 1694 from the *Siebenburgische Hofkanzlei* in Vienna. In 1697 Apafi was induced to abdicate The Porte recognized the situation under the Peace of Karlovitz (1699). In Transylvania itself the resistance to the imperial troops and the Jesuits ceased only after the Peace of Szatmár (1711) In 1721 the Transylvanian diet accepted the Pragmatic Sanction

During the succeeding century the pressure of Catholic and bureaucratic rule gradually broke down the old individuality of Transylvania, which was promoted, in compensation, to the title of a Grand Principality in 1765 The privileges of the Széklers had already almost vanished in the 16th century and many of them had sunk into serfdom. In the 18th the Saxons were in danger of following suit, but were saved by their great minister, Brukenthal. Some of the Rumanians, on the other hand, emerged for the first time from serfdom when Maria Theresa extended the system of the Military Frontier (*q v*) to three Wallach districts in Transylvania in 1766 They had already acquired a measure of religious liberty under the union of 1698–99, which allowed any Orthodox priest in Hungary immunities equal to those of the Catholics conditional on his accepting certain dogmas The creation of the Uniat Church was probably not meant as an attempt to play off the oppressed against the dominant classes; but the Rumanians, who were largely reinforced during the 18th century by refugees from the Phanariot régime in Wallachia and Moldavia, were at last able to develop a national consciousness The visits of Joseph II. to Transylvania (1773, 1783) gave rise to a rumour that the serfs were to be liberated and armed against their masters In 1785 the Rumanian peasants, led by Nicola Horea, rose and had massacred many Magyar nobles before the revolt was suppressed. On Joseph's death, after recanting his reforms in Hungary, the Rumanians submitted to his successor, Leopold II, the ***supplex libellus Valachorum***, in which they prayed to be set on an equality with the other nationalities and inaugurated the "Vlach controversy" in modern politics by appealing to their "ancient rights" as the autochthonous inhabitants of Transylvania The document was passed by Leopold to the Transylvanian diet of 1790–91, which, itself busily engaged in reaffirming its position after the disturbing Josefinean interlude, rejected it decisively and restored the old constitution. Actually, however, under Francis I and Ferdinand II there was little liberty for any party. Meanwhile, the wave of the Magyar national revival swept through Transylvania, bringing with it a strong demand among the Magyars for full union with Hungary and creating a corresponding antagonism among the non-Magyars.

On the outbreak of the revolution of 1848 the Magyars petitioned for union with Hungary, promising the Rumanians the abolition of serfdom and other reforms in return for their support. The Rumanians, however, rejected the alliance, and at the "Field of Liberty" of Blaj (Blasendorf) declared themselves a free nation, forming an integral part of Transylvania, and swore fealty to the Hapsburgs (May 15). A political programme, based on "the principles of fraternity and liberty," was drawn up, but rejected by the diet at Klausenburg (Cluj), which proclaimed the union with Hungary, the Saxon representatives accepting this decision by a majority, and declared the new Hungarian laws to be sufficient guarantee that all necessary reforms would be granted—

a conclusion also reached by a commission of the Hungarian parliament In the subsequent fighting between the Hungarian and the Austro-Russian troops, much of which took place in Transylvania, both Saxons and Rumanians took up arms against the Magyars, and a very bitter racial war resulted. The Austrian constitution of 1851, which abolished both the Military Frontier and the Saxon privileges, treated all nationalities with equal severity, and the reaction affected all equally heavily The diploma of Oct 20, 1860, restored the old constitution and the Hofkanzlei, but these were abolished when Transylvania became an integral portion of Hungary under the Austro-Hungarian Compromise of 1867. In the following year it was reorganized in "comitats" with the rest of Hungary

From 1868–1918 Transylvania was dominated by the Magyar racial policy. The basic Nationalities Law of 1868 was in theory extremely liberal, but in practice remained almost a dead letter The Saxons, in view of their numerical inferiority, confined themselves to building up a close organization for the defence of their social and religious individuality. In spite of this they lost ground, especially after their ancient national status was abolished in March 1876. The Rumanian national movement was more active. In past centuries it had been essentially social rather than national. The idea of uniting all Rumanians in one body politic had, indeed, been mooted, but so long as the Danubian provinces remained under Turkish suzerainty the suggestion most commonly put forward, even by Rumanian rulers, *e g*, Michael the Brave and Matthew Bassarab, had been for a Rumanian state under Habsburg rule. Austria, however, lost her last chance of acquiring Moldavia and Wallachia through her unskilful diplomacy during the Crimean War; by the Compromise with Hungary she sealed the alienation of her Rumanian subjects. The immediate social struggle was ended by the abolition of serfdom in 1853–54; the agitation for a land reform dated chiefly from the 20th century The national struggle proper occupied the chief attention of the new Rumanian intelligentsia and middle-classes. A Rumanian irredenta, though invited by the creation of an independent Rumanian kingdom, never assumed the proportions of the Serb, owing to the discouragement given it by King Charles of Rumania, who was allied with Austria-Hungary, but in the last years before the World War it was increasingly furthered by nearly all educated elements in Rumania; and the severity of the measures taken in Transylvania during the War by the Hungarian Government and military, especially after the Rumanian advance into Transylvania in 1916, showed that practically all Rumanians desired the dissolution of Austria-Hungary.

Union with Rumania.—In Oct 1918 the Rumanians of Transylvania announced their decision to direct their own destinies. On Oct. 27 a National Council was established at Arad; and on Dec 1 a Convention assembled at Alba Julia and proclaimed the union of Transylvania with the kingdom of Rumania, at the same time promising to respect the rights and liberties of the other nationalities. The Saxons adhered to this resolution on Jan. 21, 1919; the representatives of the Magyars not till 1921, and then under protest. The union was thus carried through without calling on the secret treaty of Aug. 17, 1916, under which the Allies had promised Transylvania to Rumania The final frontier was determined by the Treaty of Trianon (June 4, 1920). The effect was to leave a western fringe with a very considerable Magyar population; it represented the results of a difficult endeavour to reconcile very conflicting ethnical and other claims The Rumanian Minorities Treaty guaranteed the rights of the non-Rumanian population; but, for all that, the transference of the administration from Magyar to Rumanian hands was accompanied by considerable friction. In part this was due to the discontent prevalent in Hungary on account of the new frontier, in part to certain undeniable weaknesses in the new régime, aggravated by the confusion of the post-war period. In particular, complaints were brought forward by the Magyar landowners, and supported by the Hungarian Government, regarding the application of the land reform, which had deprived the large landowners of their estates against a compensation which had been fixed in nominal Rumanian lei, no account being taken of the depreciation of the currency. It was also very widely alleged that the law was being applied in a manner detrimental to the non-Rumanian nationalities. The controversy, which aroused great bitterness, came before the League of Nations in April 1923 and Sept. 1927, each disputant showing great determination to frustrate or repudiate any decision, unless favourable to itself.

Cabot, *The Racial Conflict in Transylvania* (1926). The statements of all parties directly concerned in the Transylvanian conflict should be accepted with the greatest caution. (C. A. M.)

TRANSYLVANIAN MOUNTAINS. This is an inclusive name for the mountainous region which abuts against the south-eastern end of the Carpathian range south of the Jablonica pass. In the east they form a continuation of this range but across the rest of the tract the mountains are arranged in scattered groups, in broken connection with one another, the land between forming the Transylvanian basin Formed in Tertiary times, they are part of the eastern arm of the Alpine fold-system which passes in a wide arc through the Carpathians, turns abruptly westward at Pietrite Fetei into the Transylvanian Alps, again turns almost as abruptly southward at Reteizat through the Szretinye mountains and across the Danube at Iron Gates to turn eastward into the Balkan mountains

The eastern mountains, the Moldavian Carpathians, are divided parallel to their trend by the upper valleys of the Mureşul and the Oltu, separating the outer (eastern) ranges which consist of highly folded *Flysch* (Cretaceous, Eocene and Oligocene) lying upon an (inner) crystalline massif of plutonic rocks, gneisses and schists with Carboniferous, Permian and Triassic rocks The western of these two ranges, the Harghitei complex of Tertiary volcanic rocks (andesites, andesitic tuffs, etc.), forms the eastern boundary of the Transylvanian basin and through it break the rivers Oltu and Mureşul. The Transylvanian basin seldom rises above 1,600 ft. in altitude and is covered by Miocene deposits The southern boundary is formed by the Transylvanian Alps which consist almost entirely of a crystalline massif of gneiss, schist and granite with a very narrow and broken fringe of *Flysch* on its southern (outer) edge. This forms the most continuous range in the region and contains the highest peak (Negoiul, 8,320 ft.).

The mountains of the south-west and west, which do not form a continuous range but are isolated by wide valleys, have a more complex structure than the Transylvanian Alps, for around crystalline massifs, which beneath the covering rocks are probably continuous with that of the latter chain, are Triassic, Rhaetic, Jurassic and Cretaceous beds and to a less extent Carboniferous and Permian Here are three main masses, the Szretinye mountains, the Transylvanian Ore-mountains and the Bihor mountains. Here, as well as in the Nagybánya district in the north, are Tertiary volcanic rocks of andesitic composition associated with which are important gold and silver lodes. Some of the mines (*e.g.*, Roşia-Montană [Verespatak]) have been worked since Roman times and the district still contains the most valuable gold deposits in Europe These volcanic rocks are probably associated with north to south faulting which occurs in this region. The northern boundary is less well defined and comprises a low range in the west with the higher range, the Ródna Hegység, farther east.

There are evidences of past glaciation amongst the highest peaks which nowhere reach 9,000 ft, so that none of them are permanently snow-capped. Precipitation in the Transylvanian basin averages 24 in. and great extremes of temperature are experienced This basin cannot be called a plateau for it does not possess extensive plains but is cut up by a network of valleys formed by mountain streams that drain into it from the peripheral ranges The three main streams are the Great Sameşul, which, draining the northern half of the basin, flows north-west to join the Theiss; the Mureşul, which crossing from east to west enters the Hungarian plain along the southern scarp of the Transylvanian Ore-mountains and also joins the Theiss; and the Alt

which breaks through the Transylvanian Alps by the Turnul-Ros pass to join the Danube. Other passes in this range, all of which are followed by railways, are the Bodza, Tömös, Vulcan and Teregova, whilst those in the Moldavian Alps are the Prislopul, Rodna, Borgo, Tölgyes, Békás, Gyimes and Oitoz passes, several of which are used by railways. (*See* RUMANIA)

TRAP, a mechanical device for snaring or catching anything, and especially wild animals. The term trap is also used to designate a wooden instrument, shaped something like a shoe, used in playing trap-ball; a machine used for throwing clay pigeons or balls into the air; a bent or partitioned chamber, as in a drain pipe (*see* PLUMBING), in which the liquid forms a seal to prevent the passage of sewer gas, etc.; and the term has been used colloquially to designate a light horse carriage.

Trap is derived from O.E *treppe* or *traēppe,* properly a step, as that on which an animal places its foot and is caught, *cf.* Ger. *Treppe,* a flight of stairs Traps for animals are of great antiquity and no savage people has ever been discovered, whatever its culture, that did not possess some variety of snare.

In the most primitive form of wild animal trap no mechanism need be present, *e g.*, a cavity into which the animal walks, as the pitfall of the Arabs and Africans or the snow-hole of the Eskimos. Dr O. T Mason has divided traps into three classes. *enclosing* traps, which imprison the victim without injury; *arresting* traps, which seize the victim without killing it, unless it be caught by the neck or round the lungs; and *killing* traps, which crush, pierce or cut to death.

Enclosing traps include the pen, cage, pit and door-traps. Pen-traps are represented by the fences built in Africa into which antelopes and other animals are driven, and by fish-seines and pound-nets. Among cage-traps may be mentioned bird-cones filled with corn and smeared with bird-lime, which adhere to the bird's head, blinding it and rendering its capture easy; the fish-trap and lobster-pot; and the coop-traps, of which the turkey-trap is an example This consists of a roofed ditch ending in a cul-de-sac into which the bird is led by a row of grains of corn Over the further end a kind of coop is built, the bird, instead of endeavouring to retrace its steps, always seeks to escape upward and remains cooped Pitfalls include not only those dug in the earth, at the bottom of which knives and spears are often fixed, but also several kinds of traps for small animals. One of these consists of a box near the top of which a platform is hung, in such a way that, when the animal leaps upon it to secure the bait it is precipitated into the bottom of the box, while the platform automatically swings back into place.

The door-traps range in size from the immense cage with sliding door in which such beasts as tigers are caught, to the common box-trap for mice or squirrels, the door of which falls when the spindle upon which the bait is fixed is moved Four classes of arresting traps are: the mesh, the set-hook, the noose and the clutch. The mesh-traps include the mesh and thong toils used of old for the capture of the lion and other large game, and the gill-net in the meshes of which fish are caught by the gills To the set-hook division are reckoned the set-lines of the angler, several kinds of trawls and the toggle or gorge attached to a line, which the animal, bird or fish swallows only to be held prisoner. The noose-trap class is a very extensive one. The simplest examples are the common slip-noose snares of twine, wire or horsehair, set for birds or small mammals either on their feeding grounds or runways, the victim being caught by the neck, body or foot as it tries to push through the noose. When the noose is used with bait it is generally attached to a stout sapling, which is bent over and kept from springing back by some device of the "figure-4" kind. This is constructed of three pieces of wood, one the horizontal spindle on which the bait is placed, one the upright driven into the ground, and the third the connecting cross-piece, fitted to the others so loosely that only the strain of the elastic sapling keeps the trap together When the victim tries to secure the bait he dislodges the cross-piece and is caught by the noose, which is spread on the ground under the bait or is so arranged as to encircle the neck

Besides the figure-4, several other very effective trigger devices are in use. There are two widely different types of clutch-traps: bird-lime and other tenacious substances, and jaw and clap-traps The simplest form of the first is adhesive fly-paper Some examples of the clap-trap are the clap-net, consisting of two nets laid flat on the ground and attached to cords in such a manner that they fly up and close when the draw-cord is pulled by a concealed trapper; and the various other spring-traps used by bird-catchers The jaw-traps are the most important class of device for the capture of fur-bearing animals Steel-traps consist of two jaws, with or without teeth, which are worked by powerful single or double springs and are "sprung" when the victim steps upon the "pan," which is placed between the jaws and attached to a lever They are made in many sizes, from the smallest, designed for rats, to the "Great Bear Tamer," weighing over 40 lb , with jaws of 16in in which lions, tigers and grizzly bears are trapped The steel-trap is set and concealed in such a manner that the animal must step on its pan in passing over it to secure the bait During recent years many types of traps, designed to reduce suffering and to displace the ordinary steel-trap, have been put out, but are not yet in general use

With the clutch-traps must also be reckoned the oldest form of steel-trap, now to be seen only in museums, the man-trap, which was used first about the middle of the 18th century when the systematic preservation of game rendered protection against poachers a necessity Such a trap, from Gloucestershire, is over 6ft. long, has 19in serrated jaws and weighs 88 pounds Another form of man-trap, the spring-gun, belongs to the next category, the killing traps, which are divided into traps of weight, point and edge. The most important of the weight class is the dead-fall, of which the typical form consists of a pen over whose narrow entrance one or more logs are laid across a lighter log, which is balanced upon a spindle necessarily struck by the entering animal, causing the logs to fall upon its back In some cases the bait is attached to the spindle itself The dead-fall was always the favourite trap of the American Indians, and is in use among many aboriginal tribes in Africa and South America A slab of stone is often used as a weight The common mouse-trap which kills either by a blow or strangulation is a variety of dead-fall Of point-traps may be mentioned those of the impaling and the missile classes An example of the former is the stake or spear placed by Arab and African tribes at the bottom of pitfalls for big game Another impaling trap common in Africa is the harpoon down-fall, generally used for the hippopotamus It consists of a heavily weighted harpoon suspended in such a way that the animal, passing beneath, breaks a cord and precipitates the harpoon upon itself. Another example of impalement is the hawk-trap, consisting of a circle of stout sharp wires, in the centre of which a live fowl is placed. A bird of prey attempting to secure the fowl is impaled upon the wires Of missile-traps the most universal are the ancient spring-bow and its modern representative the spring-gun This is fixed upon stakes, or against a tree, with a line attached to the trigger and stretched immediately in front of the muzzle An animal pressing against the string pulls the trigger and discharges the piece into its own body An arrangement of sticks holding the bait in front of the muzzle is sometimes substituted for the string Of edge-traps a curious example is the wolf-knife of Western America, which consists of a very sharp blade embedded in frozen fat One of the wolves, licking the fat, cuts its tongue and a flow of blood ensues, with the result that not only the wolf itself but its companions become infuriated by the smell and taste, and the wounded beast, and often many of the others, are killed and devoured The Alaskan knife-trap for large game consists of a heavy blade attached to a lever, which, when released by the animal biting at the bait, moves over and strikes the victim

See *Shifts and Expedients of Camp Life,* by W. B. Lord (1871); *Camp Life and the Tricks of Trapping,* by W. H. Gibson (1902); O. T. Mason, "Traps of the American Indians," *Annual Report,* Smithsonian Institution, for 1901, *The Story of the Trapper,* by A. C. Laut (1903).

TRAPANI (anc. *Drepanum*), a city and episcopal see of Sicily, capital of the province of the same name, situated on the west coast, 3 m W of the Monte San Giuliano, which rises above it, 121 m. W by S of Palermo by rail, and 47 m direct. Pop. (1921) town 56,625, commune 61,174. The ancient Drepanum

(δρέπανον, a sickle, from the shape of the low spit of land on which it stands) was originally the port of Eryx. It is represented by Virgil in the *Aeneid* as the scene of the death of Anchises. It was an important Carthaginian naval station in the First Punic War (260 B.C), part of the inhabitants of Eryx being transferred thither. Near Drepanum the Roman fleet was defeated in 250 B C., while the struggle to obtain possession of it ended in the decisive Roman victory off the Aegates Islands in 241, which led to the conclusion of peace (*See* PUNIC WARS) Under the Norman kings, at the time of the first crusade, it became a place of importance; it was a residence of the Aragonese kings. In the 16th and 17th centuries it was strongly fortified

There are some fine Gothic and baroque palaces, and a few churches with interesting details. Trapani has a harbour of some importance There are also large salt-pans to the south of the city, extending along the coast as far as Marsala.

TRAPPISTS, Cistercian monks of the reform instituted by Armand J. le B de Rancé (*q v*), abbot of La Trappe, 1664 La Trappe was a Cistercian abbey near Soligny, in the diocese of Sées, in Normandy, founded 1140. It suffered grievously from the English wars and from commendatory abbots. Armand Jean de Rancé became commendatory abbot at the age of ten, 1636; and on his conversion from a worldly life he began to interest himself in his abbey and conceived the project of restoring the monastic life therein, 1662 With this object he visited La Trappe, but the monks were recalcitrant and threatened his life, through the intervention of Louis XIV he was able to pension them off: they were replaced by a community of Cistercians of the strict observance, and the monastic buildings, which had fallen into ruin, were repaired at de Rancé's expense. He himself then entered the novitiate in one of the reformed Cistercian abbeys, and came to La Trappe as regular abbot, 1664. He persuaded his community to adopt a manner of life beyond Cistercian practice, and far beyond St Benedict's rule. The Trappist régime is probably the most penitential that has ever had any permanence in the Western Church Yet it attracted vocations in such numbers that de Rancé had 300 monks under him Through age and ill health he resigned his abbacy in 1695, and died five years later.

During the 18th century La Trappe continued faithful to de Rancé's ideas, but the observance spread only into two monasteries in Italy It was the dispersal of the community at the French Revolution that turned the Trappists into a congregation in the Cistercian order and finally into a separate order. Dom Augustine de Lestrange, the novice-master at the time of the suppression in 1790, kept twenty of the monks together and obtained permission for them to settle at Val-Sainte in Fribourg, Switzerland Here they made their life still stricter than that of La Trappe, and postulants flocked to them in such numbers that in two years' time colonies went forth to establish Trappist monasteries in England, Belgium, Piedmont, Spain and Canada, and in 1794 Dom Augustine was named by the Holy See Father Abbot of all these foundations, thus formed into a congregation. In 1817 they returned to La Trappe, many new foundations were made, and by Dom Augustine's death in 1827 there were in all some seven hundred Trappist monks. In the course of the century three or four congregations arose—a Belgian, an Italian, and two in France—each with a vicar subject to the general of the Cistercians In 1892 these congregations were united into a single Order of Reformed Cistercians, or of Strict Observance, with an abbot-general resident in Rome and independent of the general of the Cistercians of the Common Observance In 1898 the Trappists recovered possession of Citeaux, the mother-house of the Cistercians, secularized since the Revolution, and it was declared to be the mother house of the Reformed Cistercians.

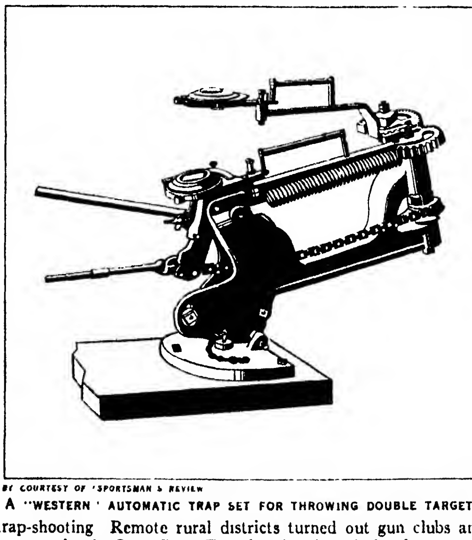
The Trappists are a thriving and vigorous order, represented in all the countries of western Europe; also in the United States and in Canada. Besides they have a house in China, one each in Japan, Asia Minor, Palestine, Bosnia and Dalmatia, and four in various parts of Africa. In heathen countries the Trappists now give themselves up to missionary work

The first Trappist nunnery was the abbey of Les Clairet, near Chartres, which de Rancé persuaded to adopt his reforms Dom Augustine de Lestrange established another in 1796, and now there are fifteen with 350 choir nuns and 500 lay sisters. One is in England at Stapehill, near Wimborne, founded in 1802.

BIBLIOGRAPHY —*See* the *Lives* of de Rancé. A minute account of the observance is in de Rancé's *Règlemens de la Trappe* (1701). The beginning of the reform is told by Helyot, *Histoire des ordres religieux* (1718), vol. vi. ch. 1; the developments under Dom Augustine de Lestrange are described in the supplementary matter in Migne's *Dictionnaire des ordres religieux* (1858) The whole subject is well treated by Max Heimbucher, *Orden u. Kongregationen* (1907), vol. 1 § 48; in the *Catholic Encyclopaedia;* in Wetzer und Welte, *Kirchenlexicon* (2nd ed), and Herzog, *Realencyklopädie* (3rd ed). A realistic and sympathetic picture of Trappist life is the redeeming feature of J Huysman's *En route.* (E. C. B)

TRAP-SHOOTING, shooting at live or clay birds released from traps In Great Britain shooting at live birds prevails, but is widely condemned In the United States the sport is almost wholly confined to shooting artificial birds. Trap-shooting began in America in 1825.

Cincinnati, O , is the recognized home of organized trap-shooting in the United States, a club having been established there in 1831 Glass balls were the first inanimate targets, with an improvement later in the form of feathers inside the globes which gave an impression of game when struck Spring-board traps catapulted the targets into the air Keen shots began club organization over the country and regular competitions ensued New model traps were invented and with them trap-shooting passed from the glass ball stage to the mechanism which tossed off the first saucer-shaped clay disc or "brittle pigeon" The Ligowski trap and bird, the latter equipped with a sort of flipper which the machine engaged and slung to various tangents, were pioneers These earlier traps were set in rows behind earth ramparts Poor trap delivery, small rotation imparted to targets, slower powders and tough composition of the "birds" caused the lower scores of those days. But with the advent of smokeless powders, chilled shot, better targets and traps and above all better choke-boring of guns, scores mounted and with them nation-wide interest in



BY COURTESY OF "SPORTSMAN & REVIEW"

A "WESTERN" AUTOMATIC TRAP SET FOR THROWING DOUBLE TARGETS

trap-shooting Remote rural districts turned out gun clubs and, as a result, the Inter-State Trapshooting Association became the governing body of the sport in the United States

Subsequently came the American Trapshooting Association with which were connected, more or less as financial backers, the gun and ammunition interests of the country. The American Trapshooting Association was in turn passed over to the Amateur Trapshooting Association in 1923. With the formation of the latter association, control and direction of trap-shooting in the United

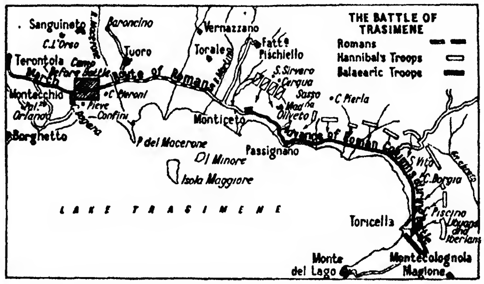
States (with Canadian affiliation) passed directly into the hands of the amateurs as distinguished from gun and ammunition firms having a commercial interest in the sport. Amateur control has resulted in the foundation at Vandalia, O, of a permanent trap-shooting home and club grounds which is probably the most elaborate layout of its kind in the world Here, usually in late August, is decided, after a week of steady firing, the Grand American Handicap programme, culminating in the main event of that name, the "Grand American."

Trap-shooting in the United States has shown a gratifying increase since passing into the hands of the Amateur Trap-shooting Association. A conservative estimate of the number of targets fired at in a season's trap-shooting in the United States and Canada, approximates 75,000,000, at least a million of which are thrown during one week's programme of the Grand American The world's record long run at single targets is held by a Californian, A J. Stauber of Los Angeles—694 straight kills. Stauber, in 1927, also compiled in his class shooting the highest percentage ever recorded in trap-shooting, breaking 1,461 targets out of 1,475 or an average of 99 05%. Mark Arie, of Champaign, Ill, broke the world's record for shooting double targets (two thrown simultaneously at different angles) in 1926 at Denver, Colo, breaking 168 consecutively 198 out of 200 for the high score An outstanding feature of the year 1927 was the breaking of 455 straight targets during the Grand American Handicap programme by Guy Dering, president of the American Trapshooting Association Notable among women trap-shooters who have won national recognition are Mrs Frank Butler (the late Annie Oakley) and Mrs Adolph Topperwein who achieved feats in trap-shooting which should last for years

TRASIMENUS, LAKE, a lake of Umbria, Italy, 12m W from Perugia, 843ft above sea-level, 50m in circumference, and 8m to 14m across (Lat. *Trasumenus Lacus;* Ital *Lago Trasimeno*). Having no natural outlet, it was formerly subject to sudden rises, which occasioned inundations, and these in turn malaria. An artificial outlet was completed in 1898 from the south-east corner of the lake to the Caina, a small tributary of the Tiber The locality was the scene of the second great defeat suffered by the Romans during the Second Punic War.

In the early spring of 217 B C Hannibal left the winter quarters (probably near Modena or Bologna) to which he had withdrawn after the victory of the Trebia (*q v*) and crossed the Apennines, continuing his march by a shorter route than the usual one, a route which obliged him to march through an inundated and marshy district for four days and three nights. Which pass it was that he took has been much discussed, but it is most likely that he followed the modern route from Bologna to Bagni della Porretta, and thence went by the Collina pass to Pistoia From here he passed through the (at that time) marshy district between Pistoia and Florence, and after resting his troops advanced towards Cortona and Lake Trasimenus, his object in taking this route being, as Polybius tells us, to move onto the rear of the consul Flaminius, who was at Arretium (Arezzo) and, by this strategic surprise, gain an opportunity to fight with the advantage. Fulfilling Hannibal's calculation, Flaminius, on hearing that Hannibal was plundering the countryside, hastily started in pursuit, while the other consul Servilius, who was at Ariminum, marched along the Via Flaminia, their object doubtless being to attack him from two sides before he could reach Foligno But Flaminius advanced rapidly and without taking the most elementary precautions of scouting. He probably reached the lake in a single day's march from Arezzo, in any case late in the evening, and encamped by it, probably to the east of Monte Gualandro and west of Tuoro, and started early on the following morning along the north side of the lake, which was covered with a thick mist.

Hannibal, as he marched along the shores of the lake, had not failed to notice the exceptionally good opportunities of surprise which the terrain afforded. From the hill of Montigeto, a little to the west of Passignano, to Torricella, where the road to Perugia and Foligno leaves the lake and climbs some 300ft. in half a mile to the pass of Montecolognola over the hills which surround it, is a distance of some six or seven miles. For the greater part of this the road runs along a narrow level strip of ground completely commanded by the hills which rise from the lake, while the ascent to the pass is shut in by hills in front and on each side, with the lake behind; so that it corresponds extremely well with the description of Polybius Even without the mist, which was of course an added advantage, Hannibal would have been able to conceal the greater part of his troops behind hills or in dead ground at a comparatively short distance away



PLAN OF BATTLE BETWEEN THE CARTHAGINIANS AND THE ROMANS

from the road Flaminius, on the other hand, was in an exceptionally unfavourable situation for resistance, there were three points at least at which his army of some 30,000 men (which, marching in column, would have formed a length of some ten m) could be easily split up by an attack, the narrow strip of land along the shores of the lake afforded them no room for retreat nor to rally, and there was no point where they could easily break through to the north

Hannibal therefore encamped on the pass, from which he could command a view of the defile as far back as Passignano, and kept his heavy Spanish and African troops under his own command to hold the pass, while the light troops were placed on the left, behind Montecolognola itself, and the Gauls and cavalry formed the right wing, which extended along the hills above the lake as far as Montigeto, the cavalry being placed at the beginning of the defile, and concealed behind the hill of Montigeto, so as to be able to close the defile as soon as the last units of Flaminius' army had entered it. So the Romans marched on to their doom; and when the head of their column came into contact with the troops in the centre at the pass of Montecolognola, concealment was neither possible, nor indeed necessary, and Hannibal gave the signal for a general attack. The greater part of the army was already in the trap and was attacked on all sides from the higher ground, so that, we are told, the centurions and tribunes could not even understand the situation, still less do anything to help it, and the Romans were mostly slain in their marching formation, without having any opportunity of defending themselves, or realizing what was to be done Many of them were driven into the lake and met their death there.

The head of the column, however, which was naturally more prepared to offer effective resistance, to a number of some 6,000 men, rallied and advanced against the pass They succeeded in piercing through the light troops on Hannibal's left in a southerly direction, and only when they had done so found that there were no other troops opposed to them From the high ground they had reached, they were able, now that the mist had cleared, to see the full extent of the disaster, but as they were unable to offer any assistance they marched off to an unnamed Etruscan village, where they surrendered to Maharbal on the following day, in the vain hope of being set free if they laid down their arms; but with the rest of the prisoners (another 10,000 or so) they were all thrown into chains. The number of killed was about 15,000; while the Carthaginian losses were only about 1,500

It is the only instance in history of a general lying in ambush with the whole of a large army and accounting for practically the whole of the troops opposed to him, and it was, thanks to the favourable nature of the ground, the carelessness of Flaminius and

the fortunate circumstance of the morning mist, a brilliant success. Kromayer's account of the battle, which we have followed, fits in with the account of Polybius and with the actual terrain better than any of the rival theories which have been advanced. Of these, the only one deserving of consideration is that which asserts that the battle took place a good deal farther to the west, in the valley of Montigeto, near the village of Tuoro But here there is no long defile where an army on the march could be attacked—only a quite short one at Borghetto, close to the shore of the lake and too narrow for the passage of an army.

Immediately after this terrible defeat the Romans suffered a minor discomfiture Servilius, who was hastening to his colleague's assistance, had sent his cavalry, some 4,000 men, under C. Centenius, ahead of his main body. Hannibal sent Maharbal with the light troops and part of his cavalry against him, and an engagement followed in which, according to Polybius, the Romans lost half their forces, while the rest sought shelter on a hill, but were surrounded and taken prisoners the next day. (*See* CALLICULA)

See J Kromayer, *Antike Schlachtfelder*, iii. 1, 148 *sqq.* (1914). (T. A)

TRASS, the local name of a volcanic tuff occurring in the Eifel, where it is worked for hydraulic mortar. It is a grey or cream-coloured fragmental rock, largely composed of pumiceous dust, and may be regarded as a trachytic tuff It much resembles the Italian puzzolana and is applied to like purposes Mixed with lime and sand, or with Portland cement, it is extensively employed for hydraulic work, especially in Holland; whilst the compact varieties have been used as a building material and as a fire-stone in ovens Trass was formerly worked extensively in the Brohl valley and is now obtained from the valley of the Nette

TRAUN, OTTO FERDINAND, COUNT VON ABENSPERG UND (1677–1748), Austrian field marshal, was born at Oldenburg on Aug 27, 1677, of a noble family In 1693 he left the University of Halle to serve with the Prussian forces in the Low Countries After seeing much service in the War of the Grand Alliance, he entered the imperial army.

In the War of the Spanish Succession, Traun served with distinction in Italy and on the Rhine till 1709, when he became lieutenant-colonel and aide-de-camp to Field Marshal Count Guido Starhemberg (1654–1737) in Spain A year later, he was made colonel, and in 1712 chief of a regiment of foot At Francavilla in Sicily (June 20, 1719) he received a severe wound He was promoted General-Feldwachtmeister in 1723 In 1727 he became governor of Messina, and in 1733 lieutenant field marshal.

In 1734 he won a European reputation by his defence first of the pass of S. Germano and then of the half-ruined fortress of Capua. He was promoted Feldzeugmeister and employed in a semi-political command in Hungary, then as commander-in-chief in north Italy and interim governor-general of the Milanese. In 1741 he was made a field-marshal In the War of the Austrian Succession (*q.v.*) he commanded in Italy till 1743, when, on the death of Field Marshal Count Khevenhüller (*q v*), he was made the principal military adviser of Prince Charles of Lorraine (*q.v*), commanding the Austrians in Bohemia and on the Danube, whose successful operating he inspired. Traun's last active service was the command of an army sent to Frankfurt to influence the election of a successor to Charles VII. He died at Sibiu (Hermannstadt), Feb. 18, 1748

TRAUTENAU: *see* TRUTNOV.

TRAVANCORE, a state of southern India Area, 7,625 sq m. In 1921 the population was 4,006,062. The state stands seventeenth among the native states of India in area and third in population Travancore extends more than 150 m. along the west coast as far as Cape Comorin, the southernmost point of the peninsula. The Western Ghats, rising to an elevation of 8,000 ft and clothed with forests, throw out spurs towards the coast, along which there is a belt of flat country of about 10 m. in width It is covered with coco-nut and areca palms, which to a great extent constitute the wealth of the country. The whole surface is undulating, and presents a series of hills and valleys traversed from east to west by many rivers, the floods of which, arrested by the peculiar action of the Arabian sea, spread themselves out into lagoons or backwaters, connected here and there by artificial canals, and forming an inland line of smooth-water communication for nearly the whole length of the coast. The chief river is the Periyar, 142 m in length. Other important rivers are the Pambai and its tributary the Achenkoil, the Kallada, and the Western Tambraparni, on which there is a reservoir irrigating about 70,000 acres Mica, monazite and lignite occur. Elephants, bison, etc., are still found in the Cardamom hills Travancore has an abundant rainfall. The principal ports are Alleppi, Quilon and Paravur; but there is no real harbour. The Cochin-Shoranur and the Tinnevelly-Quilon railways pass through the state. The Periyar irrigation project conducts water through the Ghats in a tunnel to irrigate the Madras district of Madura, for which compensation of Rs. 40,000 is annually paid to Travancore. Rice is the staple crop. Other products are pepper, tapioca, coco-nuts, cardamoms, coffee, tea and rubber in the hills Trade is large, the chief exports being copra, coir and other coco-nut products, pepper, tea, rubber, fish, etc. Cotton is woven and matting made. The capital is Trivandrum The tribute is £53,333, and there is a military force of about 1,500 The maharaja of Travancore claims descent from Cheraman Perumal, the last Hindu monarch of united Malabar, whose date is variously given from A D. 378 to 825. Though he is a Kshatriya, the succession follows the local custom of inheritance through females; consequently his *sanad* of adoption authorizes him to adopt sisters' sons For some generations the rulers have been men of education and character, and the state is conspicuous for good administration and prosperity There is a popular assembly, with women on an equal footing with men as voters and members, and a legislative council, remodelled in 1921 Primary education is free The state came into direct relations with the British government in 1923 Native Christians, chiefly of the Syrian rite, form nearly one-fourth of the population

TRAVELLER'S TREE, a remarkable tree, native of Madagascar and Réunion, with a straight stem reaching 30 ft in height and bearing at the top a number of large long-stalked leaves which spread vertically like a fan The leaf has a large sheath at the base in which water collects in such quantity as to yield a copious supply—hence the popular name. The plant is known botanically as *Ravenala madagascariensis.*

TRAVERSE CITY, the county-seat of Grand Traverse county, Michigan, U S A , on Grand Traverse bay (Lake Michigan), 150 m. N of Grand Rapids, at the mouth of the Boardman river, which widens here into a lake. It is on Federal highways 31 and 131, and is served by the Manistee and North-Eastern, the Pennsylvania and the Pere Marquette railways, motorbus lines and lake steamers The population was 10,925 in 1920 (85% native white) and was estimated locally at over 13,000 in 1928 The city has various manufacturing industries, with an output in 1925 valued at $3,460,882. It is the seat of the Northern Michigan Hospital for the Insane (1885). It was settled in 1847, incorporated as a village in 1881, and chartered as a city in 1895.

TRAVERSER. A long very shallow structure running on a number of wheels, and used to transfer locomotives, carriages, and wagons from one line of rails to another. The vehicle is hauled on to the rails which are fixed to the platform of the traverser, and the latter is then moved on its several sets of rails, by hand, steam, or electric power, until the vehicle comes into line with the desired position. There are two types, ***surface*** traversers for carriages and wagons, and ***pit*** traversers for locomotives, carriages and wagons. The surface type has the traverser tracks and the vehicle tracks at the same level, enabling through ways to be provided at any position across the traverser track. The pit design has the traverser rails sunk at a lower level, and is used chiefly in or between shops manufacturing or repairing rolling-stock. The vehicle rails are level with those from which the stock is taken and replaced, so that running on and off is simple The surface machine must have a certain depth of con-

struction, hence the rails upon which it receives the carriage must be at some distance above the ground rails, and to enable the stock to mount the traverser, ramps (inclined rails) have to be provided at the ends.

The Stokes surface traverser is built up of steel plates and girders in such a manner that the distance between the respective heights of the rails can be as little as four inches. This is important on account of the large amount of bogie stock now used, the six or eight inches difference in ordinary surface traversers being too great to enable these to mount without seriously straining or damaging the bogie and its parts. Another style, the Bowtell, has the traverser vehicle rails ramped for a short distance from the ends. Thus when the back wheels of the bogie begin to mount the ordinary ramps not on the traverser, the front wheels are mounting those on the traverser By this means a vehicle may mount a traverser which has deep construction, without injury, the angle of tilt being no greater than that which occurs when mounting the Stokes shallow type above mentioned.

TRAVERTINE, a calcareous deposit formed by springs. (*See* SINTER.)

TRAVIÈS DE VILLERS, CHARLES JOSEPH (1804–1859), French painter and caricaturist, was born at Winterthur, Switzerland, on Feb. 21, 1804 He studied first in Strassburg and later at the École des Beaux Arts in Paris He began as a portrait painter but later devoted himself almost entirely to caricature, finding that his greater talent was in that direction He was a founder of *Charivari* and later of *La Caricature* and a prolific contributor to both journals. His numerous humorous sketches appearing in the latter magazine were later gathered into such volumes as *La galerie des épicuriens, Les contrastes, Tableaux de Paris, La vie littéraire* and *Comme on dine à Paris* These burlesque studies of Parisian life, remarkable for the observational powers shown and full of wit, were immensely popular The series was continued in *Les Français peints par eux-mêmes, Les rues de Paris, Le miroir grotesque* and, doubtless the most notable of all, *Mayeux* From 1848 to 1855 he assisted in the illustration of Balzac's novels His large painting "Jésus et la Samaritaine" (1853) was acquired by the State He died in Paris on Aug 13, 1859

His brother EDWARD TRAVIÈS, also a painter, was known for his still life and his excellent animal studies

TRAVNIK, known till the 18th century as Lašva, a town in Bosnia, Yugoslavia Pop (1921) 6,334 It is built round a steep mass of rock, with the tempestuous Lašva at its base, and crowned by an old Turkish citadel. Travnik is very picturesque, with its minarets and narrow lanes, bordered by quaint old wooden houses, and its busy bazaar. There are some good modern barracks and public buildings, a tobacco factory, a State stud farm and horticultural school, and an English establishment for woodwork. Sheep rearing is the principal occupation on the surrounding heights, and some horse breeding is also carried on Many Roman remains are found in the district During the 15th century the town was the stronghold of the Bogomils, and from 1686, after the downfall of the Turks in Hungary, to 1850, it superseded Banjaluka as the capital of Bosnia.

TRAY, a flat receptacle with a raised edge used for a variety of purposes, chiefly domestic. The tray takes many forms—oblong, circular, oval, square—and is made in a vast number of materials, from papier mâché to the precious metals The tea-tray is the most familiar form; next to it comes the small round tray, usually of silver or electroplate, chiefly used for handing letters or a glass of wine. When thus employed it is usually called a "waiter." The English tea-trays of the latter part of the 18th century were usually oval in shape and sometimes had handles; mahogany and rosewood were the favourite materials Sheraton and Shearer, among other cabinet-makers of the great English period, are credited with trays of this type. These were succeeded in the early and mid-Victorian period by trays of japanned iron, which possessed no charm but had the virtue of durability. Sheffield plate snuffer-trays of satisfying simplicity were made in large numbers, and are now much sought after.

TRAY-LANDSCAPE. For discussion of various aspects *see* the articles BON-SEKI; BON-KEI; HAKO-NIWA.

TRAZ, ROBERT DE (1884–), French author, was born in Paris on June 14, 1884 He studied law in his native city and afterwards lived in England and Italy, establishing himself finally in Geneva, Switzerland, where in 1920 he founded *La Revue de Genève*. He first won notice as a novelist by his *Au temps de la jeunesse* (1908) He has since published a series of novels and short stories which have received liberal critical praise, among them *Vivre* (1910), *Les désirs du coeur; L'homme dans le rang; Complices* (1924); *L'écorche* (1927), and *La puritaine et l'amour* (1928). They indicate a writer possessed of a pleasant narrative turn, unusual observational powers, and a fine sensitiveness. He has travelled widely and his essays collected in *Dépaysments* (1923) and *Le dépaysments de l'Orient* (1926) are of more than ordinary interest

TRAZ-OS-MONTES, an ancient frontier province in the extreme N.E of Portugal, bounded on the N and E. by Spain, S by the river Douro which separates it from Beira, and W by the Gerez, Cabreira and Marão mountains, which separate it from Entre-Minho-e-Douro Pop (1920) 405,801, area, 4,163 sq.m. For administrative purposes Traz-os-Montes was divided in 1833 into the districts of Braganza (*q v.*) and Villa Real (*q.v*).

TREACLE, the thick viscid syrup obtained in the early processes of refining sugar, the uncrystallizable fluid obtained in the process of procuring refined crystallized sugar being known as "golden syrup" and the drainings from the crude sugar as "molasses" (*see* SUGAR. *Manufacture*) The word was properly and first used for a medical compound of varying ingredients which was supposed to be a sovereign remedy against snake bites or poison generally. A well-known specific was Venice treacle, *Theriaca Andromachi*, a compound of a large number of drugs reduced to an electuary, a medicinal compound prepared with honey, which dissolves in the mouth. The old French *triacle*, of which "treacle," earlier "triacle," is an adaptation, is a corruption of *thériaque*, Latin *theriaca*, Greek θηριακά (*sc.* φάρμακα), literally drugs used as an antidote against the bite of poisonous or wild animals (θήριον, dim. of θήρ, wild beast). The word "triacle" came to be used of any remedy or antidote The composition of electuaries with honey or syrup naturally transferred the name to the most familiar syrup, that obtained from the drainings of sugar.

TREADMILL, a penal appliance introduced by Sir William Cubitt in 1818 and intended by him as a means of employing criminals usefully It was a large hollow cylinder of wood on an iron frame, round the circumference of which were a series of steps about 7½in apart. The criminal, steadying himself by hand-rails on either side, trod on these, his weight causing the mill to revolve and compelling him to take each step in turn.

By the Prison Act, 1865, every male prisoner over 16, sentenced to hard labour, had to spend three months at least of his sentence in labour of the first class This consisted primarily of the treadmill, or, as an alternative, the crank The latter consisted of a small hand-wheel, like the paddle-wheel of a steamer revolving in a box. Both treadmill and crank were in time made to subserve useful purposes, but both have gradually been abolished; in 1895 there were 39 treadmills and 29 cranks in use in English prisons, and these had dwindled down to 13 and five respectively in 1901. They are now disused.

The fundamental idea of Cubitt's invention, *i.e.*, procuring rotary motion for industrial purposes by the weight of men or animals, is very old. "Tread-wheels," of this type, usually consist of hollow cylinders, round the inner surface of which a horse, dog or man walks, foothold being kept by slabs of wood nailed across at short intervals.

TREASON, a general term for the crime of attacking the safety of a sovereign State or its head. The law which punishes treason is a necessary consequence of the idea of a State, and is essential to the existence of the State. Most, if not all, nations have accordingly, at an early period of their history, made provision by legislation or otherwise for its punishment.

The law of England as to treason corresponds to a considerable extent with Roman law; in fact, treason is treated by Blackstone

as the equivalent of the *crimen laesae maiestatis* The history of the crime in the two systems agrees in this that in both the law was settled by legislation at a comparatively early period, and subsequently developed by judicial construction In both, too, there were exceptional features distinguishing this crime from other offences Treason was the subject of legislation in many of the pre-Conquest codes The laws of Alfred and Aethelred punished with death any one plotting against the life of the king The *Leges Henrici Primi* put anyone slaying the king's messenger in the king's mercy The crime was shortly defined by Glanvill, and at a greater length by Britton, and by Bracton, who follows Roman law closely

The offence of high treason was not precisely defined by the common law (1 Hale, 76), and until the passing of the Treason Act 1351 depended much on the opinions of the king and his judges That statute appears to be the answer to a petition of the Commons in 1348 (1 Hale, 87), praying for a definition of the offence of accroaching royal power, a charge on which several persons—notably Gaveston and the Despensers—had suffered The offences made high treason by the statute which still remain are these (1) to compass or imagine the death of the king, the queen or their eldest son and heir, (2) to violate the king's companion, or his eldest daughter unmarried, or the wife of his eldest son and heir, (3) to levy war against the king in his realm, or be adherent to the king's enemies in his realm, giving them aid and comfort in the realm or elsewhere, (4) to slay the chancellor, treasurer or the king's justices of the one bench or the other, justices in eyre, or justices of assize, and all other justices assigned to hear and determine, being in their places doing their offices In all cases of treason not specified in the statute the justices before whom the case came are to tarry without going to judgment until the cause has been showed and declared before the king and his parliament whether it ought to be judged treason or felony The statute, so far as it defines the offence of high treason, is still law

The statute also treated as high treason forgery of the great or privy seal, counterfeiting the king's coin and importing counterfeits thereof, and this was the law until 1832 These offences are now felonies under the Coinage Offences Act 1861 and the Forgery Act 1913 It also defined petty treason (now merged in wilful murder by s 8 of the Offences against the Person Act 1861) as the slaying of a master by his servant, a husband by his wife, or a prelate by a man secular or religious owing him allegiance Between 1351 and 1553 many new offences were made treason, but most of the Acts creating these new treasons were repealed at the earliest opportunity by parliament The reign most prolific in statutory additions to the law of treason was that of Henry VIII The Acts of this period were repealed in 1553 and the Act of 1351 was then made the standard of the offence

Besides the Acts of 1351 and 1553 the following statutes are still in force with respect to the substantive law of treason By a statute of 1495 persons serving the king *de facto* in war are not to be convicted of treason against the king *de iure* By an Act of 1702 it is treason to endeavour to hinder the next successor to the crown from succeeding, and by the Succession to the Crown Act 1707 it is treason maliciously, advisedly and directly by writing or printing to maintain and affirm that any person has a right to the crown otherwise than according to the Acts of Settlement and Union, or that the Crown and parliament cannot pass statutes for the limitation of the succession to the crown By the Treason Act 1796, made perpetual in 1817, the definition of treason is extended so as to include plots within or without the realm to cause the death or destruction, or any bodily harm tending to the death, destruction, maiming or wounding, imprisonment or restraint of the king, his heir or successors, if such plots are expressed by publishing any printing or writing, or by any overt act or deed Since that date no new forms of treason have been created.

Punishment.—The punishment of treason at common law was barbarous in the extreme The sentence in the case of a man was that the offender be drawn on a hurdle to the place of execution, that there he be hanged by the neck but not till he be dead, and that while yet alive he be disembowelled and that then his body be divided into four quarters, the head and quarters to be at the disposal of the Crown Until 1790 at common law a woman was drawn to the place of execution and there burned. In that year hanging was substituted for burning in the case of female traitors In 1814 the part of the sentence relating to hanging and to disembowelling was altered to hanging until death supervened. Drawing and beheading and quartering after hanging were abolished in 1870 The Act of 1814 in the case of men enables the Crown by warrant under the sign manual, countersigned by a secretary of State, to change the sentence to beheading Attainder and forfeiture for treason are abolished by the Forfeitures Act 1870, except where the offender has been outlawed

Trials for treason in Great Britain and Ireland were at one time frequent and occupy a large part of the numerous volumes of the *State Trials* Some of the more interesting may be mentioned Before the Statute of Treasons were those of Gaveston and the Despensers in the reign of Edward II on charges of accroaching the royal power After the statute were those (some before the peers by trial or impeachment, most before the ordinary criminal courts) of Empson and Dudley, Fisher, More, the earl of Surrey, the duke of Somerset, Anne Boleyn, Lady Jane Grey, Sir Thomas Wyatt, Cranmer, Mary Queen of Scots, Sir Walter Raleigh, Strafford, Laud, Sir Henry Vane and other regicides, William Lord Russell, Algernon Sydney, the duke of Monmouth, and those implicated in the Pilgrimage of Grace, the Gunpowder, Popish, Rye House and other plots Occasionally the result of a trial was confirmed by statute In some of these trials, as is well known, the law was considerably strained in order to ensure a conviction Since the Revolution there have been the cases of those who took part in the risings of 1715 and 1745, Lord George Gordon in 1780, Thomas Hardy and Horne Tooke in 1794, the Cato Street conspirators in 1820, Thomas Frost in 1840, Smith O'Brien in 1848

Recent Trials.—Most of the early treason trials are reported in Howell's *State Trials* and the *New Series of State Trials* There are, however, two recent trials for high treason which may be referred to A case arising out of the South African War was the trial at bar of Arthur Lynch for high treason in 1903 (*Rex* v *Lynch,* 20 Cox C C 468) It was there decided that the Naturalization Act 1870 does not permit naturalization in a foreign State at war with Great Britain, and therefore a British subject who renounces his allegiance and attempts to procure himself to be naturalized in an enemy's country in time of war is guilty of high treason It was ruled that a person cannot become naturalized in a State with which his country is at war, for the act of becoming naturalized under such circumstances is itself an act of treason The accused was sentenced to death, but the sentence was afterwards commuted and he subsequently received a pardon The most important case dealing with high treason in recent years was that of *Rex* v *Casement,* the trial at bar being reported 25 Cox C C 480, and the decision of the court of criminal appeal in the same volume on p. 503 Sir Roger Casement was charged with high treason during the World War, and it was there held by the court of criminal appeal, affirming the decision of the king's bench division at the trial at bar, that if a man is adherent to the king's enemies in his realm by giving to them aid and comfort in the realm, or if he is adherent to the king's enemies elsewhere, that is, by giving them aid and comfort elsewhere, he is in either case adherent to the king's enemies, and commits the offence declared to be high treason by the Treason Act 1351 It was also held by the king's bench division that if a man—a British subject—does any act which strengthens or tends to strengthen the enemies of the king in the conduct of a war against the king, or if he does any act which weakens or tends to weaken the power of the king and of the country to resist or attack the enemies of the king and the country, he commits the offence of giving aid and comfort to the king's enemies, and is guilty of high treason Sir Roger Casement was convicted, sentenced to death, and executed

No amount of residence abroad exempts a British subject from the penalty of treason if he bears arms against the king, unless he has become naturalized as the subject of a foreign State before the

outbreak of the war in which he bears arms. To become naturalized as the subject of an enemy during a war is (as decided in *Rex* v. *Lynch*) in itself an act of treason It is well established that an alien resident within British territory owes local allegiance to the Crown and may be indicted for high treason, and there are numerous instances of prosecution of foreigners for treason, the most recent being *de Jager* v. *Attorney-General of Natal* (1907, A.C. 326).

Court of Trial.—Four modes of trying high treason still remain, viz., impeachment, trial of a peer by his peers, trial by court-martial, and trial by jury on indictment before the High Court (generally at bar) or a court of assize or a special commission The offence is not triable at quarter sessions At common law and under the Act of 1543 a peer, and, by an Act of 1441, a peeress in right of her husband, are triable for treason before the House of Lords, or, when parliament is not sitting, in the court of the lord high steward.

Procedure.—In certain cases of treason the procedure on the trial is the same as upon a charge of murder Those cases, which are statutory exceptions from the statutory procedure prescribed for the trial of high treason and misprision thereof, are (*a*) Assassination or killing of the king, or any heir or successor of the king, or any direct attempt against his life or any direct attempt against his person whereby his life may be endangered or his person may suffer bodily harm (1800, 1817), (*b*) attempts to injure in any manner the person of the king (1842)

In all other cases of treason the procedure is regulated by Acts of 1695, 1708 and 1825 A copy of the indictment must be delivered to the accused ten days at least before his arraignment, with a list of the witnesses for the prosecution (1708) and a list of the petty jury, except in the High Court, where the petty jury list is to be delivered ten days before the trial (1825) The accused is entitled to be defended by counsel, and on application to the court may have two counsel assigned to him (1695), a right extended in 1746 to impeachments for treason Witnesses for the defence have since 1702 been examinable upon oath The accused may by the Criminal Evidence Act 1898 consent to be called as witness for the defence It is doubtful whether the wife or husband of the accused is a compellable witness for the Crown (*Archb Crim Pleading*, 27th ed, 477)

Prosecutions for treason must be begun within three years of the offence, except in cases of attempts to assassinate the king The rules as to the indictment are stricter than in the case of felony and misdemeanour much of the modern statutory power of amendment not extending to indictments for the graver offence No evidence may be given of any overt act not expressly stated in the indictment The accused is entitled to peremptory challenge of 35 of the jurors summoned for the petty jury, but they need not now be freeholders The accused can be convicted only on his own confession in open court, or by the oath of two witnesses either both to the same overt act charged, or one to one overt act and the other to another overt act of the same treason. If two or more treasons of different kinds are charged on the same indictment, one witness to prove one treason and another to prove another are not sufficient for a lawful conviction Persons charged with treason are not admitted to bail except by order of a secretary of State or by the High Court (k b d) or a judge thereof in vacation. Witnesses for the defence are examined on oath and their attendance is secured in the same way as that of witnesses for the Crown (1695)

Finally it must be noted that there can be no accessories before or after the fact to treason Every person who incites, aids or abets treason is a traitor, and must be indicted as a principal

Misprision of Treason.—This consists in the concealment or keeping secret of any high treason This offence was in 1552 declared to be high treason, but the former law was restored in 1553–54 It is an indictable common law misdemeanour, not triable at quarter sessions, and the procedure for the trial of misprision of treason is the same as in the case of high treason The punishment is imprisonment for life and forfeiture of the offender's goods and of the profits of his lands during his life The forfeitures are not abolished by the Forfeitures Act 1870 There is no case of prosecution of this offence recorded during the last century

The necessity of prosecutions for treason has been greatly lessened by a series of statutes beginning in 1744 which provide for the punishment as felonies of certain acts which might fall within the definition of treason, *e g*, piracies (1744), incitement to mutiny (1797), unlawful oaths, including oaths to commit treason (1797, 1812), and aiding the escape of prisoners of war (1812) By the Treason Act 1842 it is a high misdemeanour, punishable by penal servitude for seven years, wilfully to discharge, point, aim or present at the person of the king any gun or other arms, loaded or not, or to strike at or attempt to throw anything upon the king's person, or to produce any firearms or other arms, or any explosive or dangerous matter, near his person, with intent to injure or alarm him or to commit a breach of the peace The offence is one of the few for which flogging may be awarded

By the Treason Felony Act 1848, s 1, it was made a felony punishable by penal servitude for life within or without the United Kingdom to plot (*a*) to deprive or depose the king from the style, etc, of the imperial crown of the United Kingdom, (*b*) to levy war against the king in any part of the United Kingdom in order by force or constraint to change his measures or counsels or to put force or constraint on or to intimidate or overawe either or both houses of parliament, (*c*) to move or stir any foreigner with force to invade the United Kingdom or any of the king's dominions The plot to be within the Act must be expressed by publishing in printing or writing or by an overt act or deed For other offences more or less nearly connected with treason reference may be made to the articles LIBEL, OATHS, PETITION; RIOT, SEDITION

The Act of 1848 does not abrogate the Treason Act of 1351, but merely provides an alternative remedy But with the exception of the case of Lynch in 1903 and of Casement in 1916 all prosecutions in England for offences of a treasonable character since 1848 have been for the felony created by the Act of 1848 The procedure in the case of all the offences under the Act of 1848 is governed by the ordinary rules as to the trial of indictable offences, and the accused may be convicted even though the evidence proves acts constituting high treason. Principals in the second degree and accessories before the fact are punishable as principals, and accessories after the fact by two years' hard labour

(W F C; W DE B H)

UNITED STATES

The extent to which the crime of treason had been warped in early English history played an important part in restricting the character of the crime in America by constitutional means The United States Constitution expressly forbids Congress and the States from passing bills of attainder or ex post facto laws It further defines the crime of treason as follows "Treason against the United States shall consist only in levying war against them, or in adhering to their enemies, giving them aid and comfort No person shall be convicted of treason unless on the testimony of two witnesses to the same overt act, or on confession in open court. The Congress shall have power to declare the punishment of treason, but no attainder of treason shall work corruption of blood, or forfeiture except during the life of the person attainted" This definition embraces only treason against the United States Treason against a State is also possible and as such is governed by State laws or constitutions Treason against a State, however, usually involves an attempt to withdraw the State from the Union and thereby prevent the exercise of national sovereignty within the limits of the State and thus becomes merged in treason against the United States Consequently the crime of treason against a State is little known in American law

The constitutional definition of treason is, in part, taken from the old English Statute of 25 Edw. III Congress in 1790 and 1862 provided for its punishment by prescribing the death penalty as a maximum and a minimum penalty of five years' imprisonment and a $10,000 fine, provisions which have been carried forward into the existing laws (*U S Code, Tit 18*, §2) Congress has no power to enlarge the constitutional definition, though it may make other

offences which are treasonous in character felonies and punishable as such Thus misprision of treason, or the failure to disclose knowledge of the commission of acts of treason, is made a felony. (*U S. Code, Tit. 18, §3*), trading with the enemy, seditious utterances, insults to the flag, obstructing recruiting, and like offences have been made Federal crimes. None of these, however, carries the death penalty

The question of what acts constitute treason was brought to the forefront in the heated trial of Aaron Burr for treason in 1807 The opinion of Chief Justice Marshall in this case of *U.S.* v. *Burr*, 4 Cranch 470, 25 Fed Cas 2, sitting as circuit judge in the circuit court of Virginia, remains the landmark of American law upon the subject of treason Under the principles there laid down, levying war must comprise more than a conspiracy to make war or an intention to go to war. There must be an actual going to war, proved by open deed. The employment and exhibition of force thus becomes necessary. A secret furtive assembly without the appearance of force nor in a condition to make war, however treasonable its purpose, cannot constitute treason. It is not essential that any blow be struck provided that the assemblage be in a condition to use force and have the intention to carry out their purpose by violence A procurement to commit treason is also treason, for the American law accepts the English principle that what will make a man an accessory in felony makes him a principal in treason But in such a case it is the act of procurement of the treasonous assemblage, not the acts of the assemblage, which is the overt act of treason that must be testified to by two witnesses in order to convict him. The difficulty of proving the procurement in this manner, as procurement is generally a secret transaction, has made conviction for procurement of treason a practical impossibility. This ruling of Chief Justice Marshall, severely criticized at the time, was responsible for Burr's acquittal upon the charge of treason

The second element in the constitutional definition of treason, adhering to the enemies of the United States and giving them aid and comfort has caused less difficulty Furnishing the enemy with such facilities as are needed for the prosecution of war, such as ammunition, supplies, and means of transportation, constitutes treason. The acts which constitute treason need not be done by a citizen of the United States, but inasmuch as any alien temporarily resident within the United States and under the protection of the sovereign owes it a duty of allegiance so long as he remains within the United States, his breach of allegiance can constitute treason *Carlisle* v *United States*, 16 Wall 147 (1872).

Prosecutions for treason, as any Federal crime, are cognizable solely by the Federal courts Such prosecutions occurred mainly during three periods in American history During the American Revolution they were cognizable only by the State courts, no Federal courts for the trial of criminal cases being in existence at the time. The Whiskey Rebellion in Pennsylvania, shortly after the organization of the Federal Government, brought forth a few cases. The opposition of the New England States to the War of 1812 brought to pass additional prosecutions for treason The Civil War, of course, was most prolific of treason, but the President's proclamation of 1868 of pardon and amnesty brought all treason prosecutions to an end The World War developed no treason cases, though numerous prosecutions for seditious utterances and conduct were initiated under the Espionage and Trading with the Enemy Acts. The most famous cases of treason concerned Aaron Burr, John Brown of Harper's Ferry fame, and Jefferson Davis, president of the Confederate States Brown was convicted and hanged; the President's proclamation of pardon reprieved Davis before he came to trial (J M. LA.)

TREASURE TROVE, the legal expression for coin, bullion, gold or silver articles, found hidden in the earth, for which no owner can be discovered (*See* CORONA)

As feudalism spread over Europe and the prince was looked on as the ultimate owner of all lands, his right to the treasure trove became, according to Grotius, *jus commune et quasi gentium*, in England, Germany, France, Spain and Denmark In England for centuries the right to treasure trove has been in the Crown, who may grant it as a franchise It is the duty of the finder, and indeed of any one who acquires knowledge, to report the matter to the coroner, who must forthwith hold an inquest to find whether the discovery be treasure trove or not. Concealment is an indictable offence In the statute *De officio coronatoris* 1276 the coroner is enjoined to inquire as to treasure trove, and the Coroners Act of 1887 continues this power as heretofore In Scotland the law is similar. Such articles are presumed to have once had an owner, and, in his absence, they belong, not to the finder but to the King. Their concealment is not a criminal offence unless accompanied by intent to appropriate In India the Treasure Trove Act (16 of 1878) defines treasure as "anything of value hidden in the soil" The finder has three-fourths and the owner of the land one-fourth.

In the United States the common law, following English precedent, would seem to give treasure trove to the public treasury, but in practice the finder has been allowed to keep it In Louisiana one-half goes to finder and one-half to owner of land. Modern French law is the same, as it is also in Germany, Italy and Spain.

See Blackstone's *Commentaries;* J. Chitty, *Prerogatives of the Crown* (1820), J. Rankine, *Landownership* (new ed., 1909); J. Murray, *Archaeological Survey of the United Kingdom* (1896), containing copious references to the literature of the subject, R. Henslowe Wellington, *The King's Coroner* (1905–06).

TREASURY DEPARTMENT: *see* GOVERNMENT DEPARTMENTS

TREATIES. A treaty is a contract between two or more States The word is derived, through the French *traité* (Fr *traiter*, to negotiate) from the Latin *tractatus*, the term which from the end of the 17th century began to be used in diplomacy instead of the older technical terms *conventio publica* and *foedus* According to modern diplomatic usage the term "treaty" is confined to the more important international agreements, those of lesser or subordinate importance being embodied in "conventions" There is, however, no difference in structure between a treaty and a convention, and for the purposes of this article they may be treated as the same thing

Form.—In making a treaty it is not essential to employ any special form, and it need not on the face of it even appear to be a contract, but may take the form of a joint declaration or of an exchange of notes (as in the case of the "gentlemanly agreement" between Great Britain and the United States, in 1818, for mutual disarmament on the Great Lakes). It is, however, customary to draw up all important treaties on a fixed plan. First comes the preamble, giving the names and styles of the high contracting parties, a statement of the general objects which they have in view, the names and official designations of the plenipotentiaries charged with the negotiation, and a statement that their full powers have been verified Then follow the articles containing the stipulations agreed upon If the treaty is concluded for a definite period, this is next stated or, if it be in form perpetual, there may be a provision inserted that either party may "denounce" (*i e*, give notice to terminate) the treaty Next follows an article providing for ratification and for the time and place for the exchange of ratifications At the end is a clause stating that "in witness whereof (*en foi de quoi*) the respective plenipotentiaries have affixed their names and seals." The signatures follow, with the place and date.

Nearly all conventions likewise begin with a preamble, and in all other respects are similar to treaties. To both treaties and conventions "Additional Articles" are often appended and signed by the plenipotentiaries, with the declaration that they have the same force and value as if they had been included in the body of the treaty or convention.

Classification of Treaties.—International jurists have classified treaties on a variety of principles. For instance, a distinction has been drawn between those which represent a definite transaction such as a cession of territory (*Rechtsgeschäft*) and those which seek to establish a general rule of conduct, such as the "renunciation of war" (*Rechtssatz*). They may be classified in a more practical way according to their object, as follows: 1) political, such as treaties of peace, of alliance, of cession of territory, for arbitration, etc.; 2) commercial, including consular

and fishery conventions, and slave trade and navigation treaties; 3) social, such as the conventions establishing the international telegraphic union (1865), the universal postal union (1874), the international bureau of weights and measures (1875) and the railway traffic union (1890); 4) relating to criminal justice, *e.g.*, extradition (*q.v.*); 5) relating to civil justice, *e g*, the protection of trade-marks (Paris, 1883) and copyright (Bern, 1886), the execution of the judgments of foreign courts, etc.; 6) treaties embodying rules of international law hitherto observed, if at all, only by custom, such as methods for the peaceful settlement of international disputes (Hague Convention, 1899) or the humane conduct of war (Geneva Conventions, 1864 and 1906). In practice, however, it is of course often impossible to assign a particular treaty to any one of these classes

Requisites.—1) A treaty, like a contract in private law, is only valid when made between competent parties, *i.e*, sovereign states. This rule still holds good, though since the World War the issue has been somewhat obscured by the rather loose use of the words "sovereign" and "treaty" Thus the Articles of Agreement between the British Government and the "representatives of Southern Ireland" are commonly spoken of as the "treaty," and this has been in some quarters taken as implying the recognition of the sovereignty of the Irish Republic. The "sovereignty" now admitted in the British dominions is, however, so far as external relations are concerned, limited by agreement. The dominions are, in fact, what is known as "semi-sovereign," since they can only conclude conventions with foreign States on matters within their own competence. Moreover, this apparent departure from the accepted rule is more apparent than real, since the sovereign power is still theoretically vested in the king, in whose name all such conventions are executed The question where the treaty-making power resides in each State is answered by the municipal law in that State. In Great Britain it resides in the executive. In the United States treaties are negotiated by the President and the State Department, but can only be concluded "with the advice and consent of the Senate," and in practice the Senate shows itself very jealous of its right to amend treaties before ratification. In many countries, on the other hand, the treaty-making power is shared between the executive and the legislature only for certain purposes; in France, *e.g*, treaties of peace, treaties of commerce, those involving financial obligations or relating to the rights of French citizens in foreign countries are not valid until ratified by a majority in both chambers

2) A treaty, to be valid, must be the expression of an agreement. Unlike a private contract, however, it is not voidable on proof that one of the parties to it was subject to duress, but only if it can be proved that the individual negotiator has been so subject. Thus a treaty imposed by the victor upon the vanquished remains valid, though signed under pressure of force.

3) In modern practice a treaty, though executed by agents with full powers, is not valid until it has been ratified. Ratification, though formerly not thought to be necessary for "declarations," such as the Declaration of Paris in 1856, was expressly stipulated in those of the conferences of 1899 and 1907.

4) The question of the language employed in treaties at one time caused trouble In the 16th century all international treaties were drawn up in Latin, more rarely in French, and it was not till the 18th century that the latter was generally accepted (except by the pope and the emperor) as the language of diplomacy (the Anglo-French commercial treaty of April 11, 1713 was in Latin). The present practice is that, when treaties or conventions are concluded between more than two Powers they are drawn up in French, but when between two Powers only, there are usually two texts, one in each language, both of which are signed by the plenipotentiaries of the two parties. Such bi-lingual treaties are sometimes accompanied by a third version in French, to be decisive in case of a difference of opinion arising as to the precise meaning of the language of the other texts.

5) The making of a treaty is sometimes accompanied by acts intended to secure its due performance, *e.g.*, the occupation of the German Rhine Provinces by the Allied Powers pending the payment of the reparations imposed by the Treaty of Versailles.

6) Art XVIII of the Covenant of the League of Nations lays down that every treaty or international agreement entered into after the signature and ratification of the Treaty of Versailles by any member of the League shall be forthwith registered with the Secretariat and shall as soon as possible be published by it; and that no such treaty or international agreement shall be binding until so registered.

Duration of Treaties.—The question of when, and in what circumstances, the obligations incurred under treaties, nominally perpetual, come to an end has been the subject of much debate. A treaty may lapse naturally by the destruction of one of the States party to it, or by the object of the agreement ceasing to exist; or it may be denounced by one of the parties under powers reserved in the treaty itself Treaties are also in most cases suspended, if not terminated, by war between the contracting parties, and are therefore usually revived in express terms in the treaty of peace. More debatable is the proposition upheld by certain jurists, *e.g*, Bynkershoek, that the condition *rebus sic stantibus* is implicit in every treaty. This is laid down by Bismarck, in his *Reminiscences*, as self-evident, and he adds that "treaties are only valid so long as they are reinforced by the interests of the parties to them." In practice this was certainly often the case and—as is pointed out in the latter part of this article—no alteration was made in this respect by the London Protocol of 1871, which laid down the principle that "no Power can liberate itself from the engagements of a treaty, nor modify the stipulations thereof, unless with the consent of the contracting Powers, by means of an amicable agreement" Art. XIX. of the Covenant is an attempt to meet the difficulty It lays down that "the Assembly may from time to time advise the reconsideration by members of the League of treaties which have become inapplicable" This provision, though it suggests no more than advice backed by combined moral pressure, may be open to the objection that it tends to keep alive the agitation among the peoples discontented with the settlements made under certain treaties, by suggesting that these are not to be considered as final On the other hand, it may be argued that it provides a safety-valve for discontent by holding out the hope of a revision otherwise than by war.

The Inviolability of Treaties.—Since the whole structure of international relations, as regulated by law, is based upon treaties, it follows that anything that tends to weaken men's faith in, and respect for treaties must loosen this structure. For this reason it is all-important that treaties, once made, should be kept in the letter and in the spirit; and this again involves the principle that nothing should be included in a treaty which the parties to it are not reasonably sure that they and their successors will be able to carry out in any circumstances This was a principle firmly maintained by British statesmen during the 19th century, from Pitt and Castlereagh onwards, and led them to avoid commitments "for eventual exertion" in circumstances which could not be foreseen. For the same reason, in the days of the old diplomacy, there was in the language of treaties of peace, and of diplomatic intercourse generally, a studied avoidance of anything that might keep open old sores by any unnecessary wounding of the feelings of the vanquished Thus, while the preambles to treaties of peace were perhaps apt to lay overmuch stress on the complete cordiality of the restored relations, and so be open to the charge of being "false-friendly," they at least made it clear that the articles of the treaty which followed were the conditions on which old scores would be completely wiped out In this respect the Treaty of Versailles of 1919, *e.g.*, compares unfavourably with the Treaty of Versailles of 1783. In the former the defeated nation was compelled to confess its "war-guilt," whether it believed itself guilty or not, and the terms of the penance which was to be the price of its restoration to the communion of nations were built into the very foundations of the new international organization This has rankled in the minds of the Germans, and so has neither made for peace nor for that respect for treaty-obligations on which peace is based The framers of the treaty of 1783 were wiser. Art I. of the treaty ends with the words: "There shall be complete oblivion of and amnesty for all that may have been done or committed before or during the war which has now

come to an end."

Many treaties containing what were technically known as "transitory conventions" with reference to recognition, boundaries or cessions of territory have become, as it were, the title-deeds of the nations to which they relate This may be said to date from the treaties of Osnabrück and Munster (Westphalia) in 1648, which were the work of the first international congress, and were recognized as giving a new juridical basis to the territorial system of Europe Although, in the 18th century, treaties were more honoured in the breach than the observance, it was considered expedient to veil even the most flagrant acts of aggression under legal forms, as in the case of the three partitions of Poland which, as Gentz observed, set an unhappy precedent for the aggressions of Revolutionary France The treaties concluded between the Powers after the downfall of Napoleon (I Paris, 1814, Vienna Final Act, 1815, II Paris, 1815, and Frankfurt, 1819), represented an attempt to reorganize the European territorial system on a sound basis, by endowing the reconstituted States with unimpeachable title-deeds and ensuring their stability by establishing a balance of power between them Other treaties —the treaty of Chaumont in March 1814, and the treaty of alliance of Nov. 20, 1815 which was based upon it—provided for the continuance of the Quadruple Alliance for the purpose of watching over and safeguarding the settlement thus made And, though this "federal system" for Europe broke down for various reasons (*see* EUROPE), the idea of "the treaties" as the foundation of the European system, and of the "Concert of Europe" as their guardian, survived long enough to secure an unprecedented period of peace The principle that the treaties could not be altered without the consent of "Europe" was also more or less effectively asserted. effectively in the case of the treaties of 1831 and 1839 which separated Belgium from the Netherlands, ineffectively in the protests of France and Great Britain against Russia's violation of the terms of the Treaty of Vienna by her treatment of the Poles in 1830 and 1863

The principle of the solidarity of Europe in the matter of territorial changes was even extended to the questions arising out of the disintegration of the Ottoman empire, which had been excluded from the treaties of 1815; and the Concert of Europe survived in the Eastern Question (*q.v.*) long after the results of the Italian war of 1859 and of the wars of 1864, 1866 and 1870–71 had blown the Vienna settlement to pieces Thus the partition of Turkey was regulated by the great Powers, or some of them, in the treaties of London, 1832, 1863, 1864, and of Constantinople, 1881, with reference to Greece; and by the treaties of Paris 1856, London 1871, Berlin 1878, London 1885, with reference to Montenegro, Rumania, Serbia, Bulgaria and the navigation of the Danube As the result of the World War, these settlements have undergone very extensive and important changes; but they still have an effective existence, as the ultimate title-deeds of the Balkan States

In general, the history of treaties and treaty-making during the century that followed the Congress of Vienna showed a notable advance in the sense of international obligation as compared with the standpoint of the 18th century That the system evolved was very far from satisfactory was proved all too clearly by the World War. The League of Nations, although based on the somewhat unstable foundations of the Treaty of Versailles, is a bold attempt to substitute for 19th century methods a system better calculated to preserve peace (W. A. P.)

POST-WAR DEVELOPMENTS

The question of the sanctity or renewal of treaties is always a very serious one at the close of a war. But before the World War many great authorities held the opinion, which was expressed by some (*e g*, Professor Oppenheim) actually during the War, that the apparent "breaking-up of laws," which takes place in war is usually succeeded by a stronger emphasis upon them when peace is attained

The sanctity of treaties is a dogma open to several interpretations. For instance, many international jurists, including Bethmann-Hollweg, hold that Germany committed a breach of international law in invading Belgium in defiance of the treaty of 1839. Others, among whom is Sir Ernest Satow, an authority on both the theory and practice of diplomacy, would maintain that Germany by violating Belgium merely gave any other guaranteeing State the right to attack her. In other words, Germany risked her existence but did not specifically break international law. The difference between these two views is that the first relies upon custom, etc, to establish the sanctity of treaties, and the latter upon force The difficulty of the first view lies in the fact that custom may change For instance, it was thought to have been established in 1871 that no great Power which had joined with other great Powers in signing a treaty could violate the provisions of that treaty without the consent of the other signatories, *i.e.*, without a European conference. But in 1908 Austria-Hungary violated Article 25 of the Treaty of Berlin (1878) by annexing Bosnia and Hercegovina, and refused the demand for a conference There can be little doubt that this principle had been abandoned before 1914 The peacemakers of 1919 therefore tried to set up a state of things whereby the sanctity of treaties would be upheld by the general co-operation of all states President Wilson condensed this aspiration into a single sentence. "What we seek is the rule of law sustained by the organized opinion of mankind."

League and Regional Guarantees.—Some treaties which had proved impotent to guard certain countries, as, *e g*, those neutralizing Belgium and Luxembourg, were abrogated altogether (*cf* Articles 31, 40–1 of the German, Article 83–4 of the Austrian and Articles 67–8 of the Hungarian Treaties) The League of Nations Covenant, however, attempted to give a general guarantee of territorial integrity and independence to all the members of the League. This general guarantee, embodied in Article 10 of the Covenant (*see* LEAGUE OF NATIONS), has, on the whole, been rather watered down in its interpretation It has, in fact been succeeded by a system of special or regional guarantees Thus in the Treaty of Locarno (signed Dec 1, 1925), the demilitarization of the Rhineland, enacted by the Treaty of Versailles, Articles 42–44, was guaranteed by France, Great Britain, Germany and Italy This guarantee became effective on the admission of Germany to the League of Nations In case of need Great Britain guarantees France against the unprovoked attack of Germany, and *vice versa* Similar regional guarantees are given by France to Poland and to Czechoslovakia. The "Little Entente Treaties" (of which the first was signed Aug. 4, 1920) constitute a system of regional and special guarantees between Czechoslovakia, the Serb-Croat-Slovene kingdom and Rumania to preserve the territorial limits laid down in the treaties of St Germain, Trianon and Neuilly (*see* LITTLE ENTENTE) Similarly it was recognized in Article 26 of the Covenant that the Monroe Doctrine was "a regional understanding," which meant a practical admission by the principal Powers that the United States guaranteed other states on both American continents against the aggression of non-American neighbours.

There can be no doubt that many smaller States now enjoy greater advantages under the Covenant and special and local guarantees than did the neutralized States of the 19th century The Covenant was successfully invoked by Great Britain on behalf of Albania against the Serb-Croat-Slovene kingdom in 1921, and by Greece against Italy in the matter of Corfu in 1923. Also the inclusion of Germany in the League has in itself strengthened the system

Compulsory Arbitration.—It is a singular and interesting fact that many smaller Powers have signed the compulsory jurisdiction clause in the protocol establishing the Permanent Court of International Justice. If both litigating Powers have signed the compulsory clause a peaceful settlement can be imposed by the court. There can be no doubt that such smaller Powers as cannot depend on the guaranteed protection of larger ones feel that they are safest in this way. And it is an interesting fact that Denmark is the first State in Europe since the War to propose the reduction of her armed forces to the level of mere police. and to trust to the justice and opinion of the world for support in time of need

If it continues, the Permanent Court will in time create a standard of international justice which it can impose upon all those who have signed the compulsory clause. Were it possible, or certain, that the principal Powers would also sign the compulsory clause the peace of the world could be reasonably assured.

Abrogation or Renewal of Treaties After War.—Highly technical points are raised by this question which, though less generally interesting than those already mentioned, are none the less of some importance for the future of diplomacy. Treaties are of two kinds, bilateral between two states, multilateral between several states It is clear that in the case of bilateral treaties when State A can force State B to sign a treaty of peace after the war, A can renew or refuse to renew with B all the pre-war treaties that she chooses Germany did not question this right in bilateral treaties In the case of multilateral treaties the Allies claimed the right to refuse permission to Germany and to the enemy Powers to keep in force treaties with states not actually then engaged in the War, as, *e g*, Soviet Russia, or with neutrals who had not been in the War at all though they had severed diplomatic relations with Germany, as, *e g*, Peru and Ecuador In reply to the German protests, the Allies maintained and inserted in the German and other treaties their right to "reapply" all "multilateral treaties which seemed to them to be compatible with the new conditions arising out of the War," and "to indicate which of these treaties with Germany they intend to revive or allow to be revived" The Allies particularly insisted on making Germany grant for limited periods to the Allies themselves, or to some of them, certain terms already granted to her friends or neutrals. But they did not demand that Germany should be prevented from negotiating new instruments with states other than the Allies *after certain limited periods* had passed; *e g*, Article 268, of German Treaty Nor did Germany fail to avail herself of her power After having been compelled to abrogate the treaties of Brest-Litovsk with Soviet Russia, she negotiated the Treaty of Rapallo with them on April 16, 1922 This step evoked much protest from the Allies, and it was contended that Germany had not the right to do it

The use of power by the victor to enforce on his defeated antagonist the abrogation of treaties with neutrals is not in itself desirable; but it does not appear, on the whole, that such power, even if abused at the moment of victory, is likely to be abused for very long The special grievances or difficulties thus created by any abuses in 1919 will be well compensated for if the settlement of Europe has in fact brought a greater sense of security and permanence, whether through the agency of the League, of regional guarantee or of the Court of International Justice *See* also COMMERCIAL TREATIES (H W V T)

BIBLIOGRAPHY —L Oppenheim, *International Law*, 3rd ed (1920); Sir E M Satow, *Diplomatic Practice*, 2nd ed (1922) Each of the Peace treaties of 1919 contains a section headed "Treaties" The passages on Treaties in the *German Observations* on the draft Treaty and the *Allied Reply* are quoted in H W. V Temperley, ed *History of the Peace Conference of Paris*, vol 6 (Institute of International Affairs, 1924), 322–326, and these are authoritative expositions of the rival points of view *See* also U S A Congress, Library of, *List of References on the Treaty-Making Power* (Washington, 1920); D. F. Myers, *Manual of Collections of Treaties and of Collections relating to Treaties* (Harvard, 1922), C. Saavedra Lamas, *Traités internationaux de type social* (1924), A. Goellner, *La Revision des traités sous le régime de la Société des Nations* (1925).

RENUNCIATION OF WAR

The most important general treaty concluded since that of Versailles is the Pact of Paris or "Kellogg Pact," a multilateral treaty for the renunciation of war as an instrument of national policy (*see* OUTLAWRY OF WAR), signed at Paris by the representatives of many nations on Aug 27, 1928, and ratified by the American Senate on Jan. 15, 1929 Under this instrument the signatory Powers renounce war "as an instrument of policy" and "condemn" it as a means for settling international differences.

Whatever the moral force of such a declaration of principle may have, its practical value must not be exaggerated. It does not —as Professor Shotwell has pointed out—involve the "outlawry" of war, since it provides no sanctions. The sovereign "right" to make war is not renounced, and the right to conduct a war of defence is safeguarded, which—in the absence of any definition of "aggression"—leaves a loophole for the evasion of the obligations imposed by the treaty. Nor can the claim be admitted that the treaty introduces a new principle into international law Essentially, the Pact is much the same thing as the Act of the Holy Alliance in 1815 or the Declaration of Aix-la-Chapelle in 1818, namely, a solemn undertaking by the Powers to ensure peace The only difference is that the renunciation of war as an instrument of policy, which was implicit in the earlier acts, is explicit in the Pact.

It must be remembered, too, that though the sovereign State was regarded by the old jurists (*e g*, Vattel) as the sole judge of its own actions, it did not follow that wars of mere aggression were looked upon as legitimate This is made clear by the French jurist Jean Domat in his *Les lois civiles* (1689), where he distinguishes between wars which are, so to speak, ordeals by battle waged by the sovereigns of two nations who, "being independent of one another and having no judges in common, do justice for themselves by force of arms, when they cannot or will not have mediators to make peace between them," and wars "which are the outcome of pure violence and of the aggressions of princes or states upon their neighbours."

That this distinction was recognized by sovereigns as well has been pointed out above (*Inviolability of Treaties*) Even Napoleon, the arch-aggressor, declared solemnly, in the *Memoirs* dictated at St. Helena, that all his wars were defensive It may be suggested, then, that the importance of the Pact of Paris lies less in the enunciation of a principle than in the practical considerations which inspired it; namely, that in modern conditions war is too dangerous to use as an instrument of policy and too expensive and uncertain to employ as a method of international litigation

See J T Shotwell, *War as an Instrument of National Policy* (New York and London, 1929)

TREATY, COMMERCIAL: *see* COMMERCIAL TREATIES

TREBIA (mod *Trebbia*), a river of Cisalpine Gaul, a tributary of the Padus (Po), into which it falls some 4m west of Placentia (Piacenza) Its valley is followed past Bobbio by the modern high road from Piacenza to Genoa (88m) It is remarkable for the victory gained on its banks by Hannibal over the Romans in 218 B C Kromayer's investigations make it clear that Polybius's account, according to which the battle took place on the left bank of the river, is to be preferred to that of Livy (see *Antike Schlachtfelder*, iii 1 [Weidmann, 1914], 47 *sqq*) T Frank in *Journal of Roman Studies*, ix 202 (1919), suggests that the Placentia referred to in both accounts lay west of the river, *i e*, some 15 miles west of the later Placentia, refounded in 190.

Scipio (the father of Scipio Africanus) had advanced to meet Hannibal two days' march west of Pavia, but was defeated in a cavalry engagement, and in a forced night march recrossed the Ticinus and the Padus (probably at Placentia itself) and then took up a new position near Clastidium on the south bank of the latter river, about 20m west of Placentia while Hannibal, finding himself unable to cross the Ticinus, marched westward up the Padus until he could cross it, and so came up with the Romans and offered battle, which was, however, not accepted, and he therefore encamped five miles away from them Scipio, however, in consequence of the desertion of over 2,000 of his Gaulish auxiliaries, retreated to the further bank of the Trebia, where he was joined by Sempronius, the other consul, who had brought his army from Ariminum Hannibal followed them and encamped once more about 4m. from them: and as a decisive victory was imperative, in order that he might win over the Gauls to his side, and he had about 40,000 men, or as many as the two armies together, he did nothing to prevent their junction A successful cavalry skirmish with the Carthaginian foragers encouraged Sempronius to overcome his colleague's objections to a general engagement, and the Romans marched across the Trebia. The battlefield was almost flat, but on the south was rising ground traversed by a number of fairly deep, broad stream-beds, in one of which Hannibal concealed a force of 2,000 men under his young brother Mago, which was to have a decisive effect on the fortunes of the day At the same time he sent his 8,000 light troops out to cover the advance

of his main body of infantry, consisting of 20,000 Iberians, Celts and Libyans, while his cavalry (over 10,000, including his Celtic allies) were placed on the wings, with the elephants in advance of them. The Roman cavalry was soon driven back, and the Carthaginian light troops, Numidian cavalry and elephants attacked the Roman infantry on the flanks, so that the wings were put to flight and driven into the river, while Mago's force suddenly fell on the rear of the Roman centre and worked destruction on the rear ranks. The front ranks of the Roman centre, on the other hand, to a number of some 10,000 men broke through the Carthaginian centre with great slaughter, but seeing that the wings had been completely driven back, they took no further part in the battle, but marched in good order into Placentia, where they were joined by the cavalry. The greater part of the rest of the army, entirely surrounded by superior numbers, met its death in the river itself. The battle has been rightly described as a Cannae on a small scale, and the similarities are certainly striking, as will be seen by a comparison of the two accounts. (T. A.)

TREBIZOND (Gr. *Trapezus*), a city of Asia Minor, situated on the Black Sea, near its south-eastern angle. From the time of its foundation as a Greek colony to the present day it has always been a considerable emporium of commerce, and it was for two centuries and a half the capital of an empire. Its importance is due to its command of the point where the chief trade route from Persia and Central Asia to Europe, over the table-land of Armenia by Bayezid and Erzerum, descends to the sea Its safety also was secured by the barrier of rugged mountains (7,000 to 8,000 ft.) which separates its district from the rest of Asia Minor. So complete is the watershed that no streams pass through these ranges, and there is hardly any communication in this direction between the interior of Asia Minor and the coast. For the same reason, together with its northern aspect, the climate is humid and temperate, unlike that of the inland regions, which are exposed to great extremes of heat in summer and cold in winter. The position which was occupied by the Hellenic and mediaeval city is a sloping table of ground (whence the original name of the place, Trapezus, the "Table-land"), which falls in steep rocky precipices on the two sides, where two deep valleys, descending from the interior, run parallel at no great distance from one another down to the sea. The whole is still enclosed by the Byzantine walls, which follow the line of the cliffs and are carried along the sea-face; and the upper part of the level, which is separated from the lower by an inner cross wall, forms the castle; while at the highest point, where a sort of neck is formed between the two valleys, is the keep which crowns the whole. On each side, about half-way between the keep and the sea, these ravines are crossed by massive bridges, and on the farther side of the westernmost of these, away from the city, a large tower and other fortifications remain. The area of the ancient city is now called the Kaleh; eastward of this is an extensive quarter, and beyond this again a low promontory juts northward into the sea, partly covered with the houses of a well-built suburb, which is the principal centre of commerce. The harbour lies on the eastern side of this promontory, but it is an unsafe roadstead, being unprotected towards the north-east and having been much silted up, so that vessels cannot approach within a considerable distance of the shore. From here the caravans start for Persia. The population in 1927 was 60,975.

History.—The city of Trapezus was a colony of Sinope, but it first comes into notice at the time of the Retreat of the Ten Thousand, who found repose there. Alexius Comnenus escaped into Asia, and, having collected an army of Iberian mercenaries, entered Trebizond, where he was acknowledged as the legitimate sovereign, and assumed the title of Grand Comnenus. The empire thus founded continued to exist until 1461, when the city was taken by Mohammed II Trebizond was able to defy both the Seljuks and the Ottomans, and to maintain its independence against the emperors of Nicaea and Constantinople. The imperial family were renowned for their beauty, and the princesses of this race were sought as brides by Byzantine emperors of the dynasty of the Palaeologi, by Western nobles, and by Mohammedan princes; and the connections thus formed originated a variety of diplomatic relations and friendly or offensive alliances. The palace of Trebizond was famed for its magnificence, the court for its luxury and elaborate ceremonial, while at the same time it was frequently a hotbed of intrigue and immorality. The Grand Comneni were also patrons of art and learning. From time to time the emperors of Trebizond paid tribute to the Seljuk sultans of Iconium, to the grand khans of the Mongols, to Timur the Tatar, to the Turkoman chieftains, and to the Ottomans, but by means of skilful negotiations they were enabled practically to secure their independence. We find them also at war with many of these powers, and with the Genoese, who endeavoured to monopolize the commerce of the Black Sea. The city was several times besieged, the most formidable attack being that which occurred in the reign of Andronicus I., the second emperor, when the Seljuks, under the command of Melik, the son of the great sultan Ala-ed-din, first assaulted the northern wall in the direction of the sea, and afterwards endeavoured to storm the upper citadel by night. They failed, however, in both attempts; and in the latter, owing to the darkness, and to the occurrence of a violent storm which suddenly swelled the torrents in the ravines, their force was thrown into inextricable confusion, and they were compelled to abandon their camp and make the best of their escape from the country. So great was the strength of the fortifications that Mohammed II. might have experienced much difficulty in reducing it, had it not been for the pusillanimous conduct of David, the last emperor, who surrendered almost unconditionally

Ancient Memorials.—Several interesting monuments of this period remain at Trebizond in the form of churches in the Byzantine style of architecture. One of these is within the area of the old city, viz, the church of the Panaghia Chrysokephalos, or Virgin of the Golden Head, a large and massive but excessively plain building, which is now the Orta-hissar mosque On the farther side of the eastern ravine stands a smaller but very well proportioned structure, the church of St. Eugenius, the patron saint of Trebizond, now the Yeni Djuma djami, or New Friday mosque. Still more important is the church of Haghia Sophia, which occupies a conspicuous position overlooking the sea, about 2 m. west of the city. The porches of this are handsomely ornamented, and about 100 ft. from it rises a tall campanile, the inner walls of which have been covered in parts with frescoes of religious subjects, though these are now much defaced. But the most remarkable memorial of the middle ages that exists in all this district is the monastery of Sumelas, which is situated about 25 m from Trebizond, at the side of a rocky glen, at a height of 4,000 ft above the sea Its position is most extraordinary, for its occupies a cavern in the middle of the face of a perpendicular cliff 1,000 ft high, where the white buildings offer a marked contrast to the brown rock which forms their setting. It is approached by a zigzag path at the side of the cliff, from which a flight of stone steps and a wooden staircase give access to the monastery An antiquity of 1,500 years is claimed for the foundation of the monastery, but it is certain that the first person who raised it to importance was the emperor Alexius Comnenus III. of Trebizond who rebuilt it in 1360

TRÉBUCHET, a mediaeval siege engine, employed either to batter masonry, or to throw projectiles over walls It was developed from the post-classical Roman *onager* (wild ass), which derived its name from the kicking action of the machine. It consisted of a frame placed on the ground to which a vertical frame of solid timber was rigidly fixed at its front end. Through the vertical frame ran an axle, which had a single stout spoke; on the extremity of the spoke was a cup to receive the projectile. In action the spoke was forced down, against the tension of twisted ropes or other springs, by a windlass, and then suddenly released. The spoke thus kicked the crosspiece of the vertical frame, and the projectile at its extreme end was shot forward. In the trébuchet

the means of propulsion was a counter-weight. The axle which was near the top of a high strutted vertical frame served as the bridge of a balance, the shorter arm of which carried the counterweight and the longer arm the carrier for the shot. An alternative name for the trébuchet is the mangonel (*mangonneau*). (*See* also ENGINES OF WAR.)

TREDEGAR, an urban district of Monmouthshire, England, on the Sirhowy, 7 m. E.N.E. of Merthyr Tydfil; on the G.W R. and L.M S with a station Pop. (1921) 25,110 It stands about 1,000 ft. above sea level and owes its existence to the establishment in the beginning of the 19th century of important iron works. With the use of coal for smelting purposes the region developed industrially. Since the beginning of the 20th century, remoteness from the sea has affected the iron industry and coal exporting became more important, although this was seriously affected by the trade depression following the World War.

TREE, SIR HERBERT BEERBOHM (1853–1917), English actor and manager, was born in London, on Dec. 17, 1853, the son of Julius Beerbohm, a London merchant of German parentage; his half-brother, Max Beerbohm (*q v.*) became well known as a writer and caricaturist. Taking the stage name of Beerbohm Tree he made his first professional appearance in London in 1876 He made a striking success in 1884 as the curate in *The Private Secretary.* In September 1887 he became lessee and manager of the Haymarket theatre, London, where his representations of melodramatic "character" parts, as in *Jim the Penman, The Red Lamp* and *A Man's Shadow,* were highly successful. He played in many modern dramas, such as H A Jones's *Dancing Girl,* but also in romantic parts such as Gringoire, and in the production of so essentially a literary play as Henley's *Beau Austin;* and in classic parts his ability as a comedian was shown in *The Merry Wives of Windsor,* in which he played Falstaff, and as a tragedian in *Hamlet;* his presentations of Shakespeare carried further forward the improvements in staging inaugurated at the Lyceum under Irving In 1897 Tree moved to the new Her Majesty's theatre, where his chief successes were in Stephen Phillips's poetical dramas, and in his splendid revivals of Shakespeare (especially *Richard II.* and the *Merchant of Venice*) The magnificence of the mounting, the originality and research shown in the "business" of his productions, and his own versatility in so many different types of character, made his management memorable in the history of the London stage In the year 1907 Tree established a school of dramatic art, for the training of actors, in London; and in this and other ways he was prominent in forwarding the interests of the stage He was knighted in 1909 In 1913 he published *Thoughts and Afterthoughts,* a book of essays Tree died in London on July 2, 1917.

See Max Beerbohm, *Herbert Beerbohm Tree* (1920); Lady Tree, *Herbert and I* (1920).

TREE. The species to which the name "tree" can be given are treated under their individual titles, *e.g*, oak, ash, elm, etc.; the articles FIR and PINE treat of two large groups of conifers; general information is provided by the articles PLANTS and GYMNOSPERMS; tree cultivation will be found under FORESTS AND FORESTRY and HORTICULTURE; and the various types of tree whose wood is useful under TIMBER.

TREE-BEAR, a name given in west Africa to the tree hyrax (*Dendrohyrax*). *See* HYRACOIDEA.

TREE BURIAL. Among the Andamanese, burial upon a platform placed in a tree is an honourable form of burial, and adopted only in the case of a man or woman dying in the prime of life. It is not clear whether this honour is reserved for those who have had children—the point may be significant. A tree sometimes used for this purpose is *Ficu Laccifera,* and the belief of the natives is apparently that the souls of unborn children live in the Ficu trees, and that if a baby dies before it has been weaned its soul goes back to the tree. (*See* A. R Brown, *The Andaman Islanders* [1922].)

In Australia tree burial is forbidden to those who violate the law of exogamy—who are thereby excluded from reincarnation. In Indonesia "the position with regard to tree burial may be put in this way, that wherever a myth of origin exists which states that the first men came from trees or bamboos, then it will generally be found that the dead are placed in trees or disposed of in a way derived from tree disposal" (W. J. Perry, *Folklore,* xxvi., pt. 2, p 147) There are cases of tree burial in Central India among the primitive Gonds—the semi-Hinduized Gonds in Bengal tie the corpses of adult males to a *malua* tree previous to burial The Oraons "revere the tamarind and bury their dead in its shade One special rite among the Dravidian races is the *imli ghoutna* or 'the grinding of the tamarind' when the mother of the bridegroom grinds on the family curry stone some pods of the tamarind" (W Crooke, *Popular Religion of Northern India,* vol. 1, p 109).

TREE-CREEPER, one of the smaller British birds, and generally distributed. It is *Certhia familiaris,* and is remarkable for the stiffened shafts of its long and pointed tail-feathers, aided by which, and by its large feet, it climbs the trunks or branches of trees, proceeding upwards or outwards, generally in a spiral direction, as it seeks the small insects that are hidden in the bark and that form its chief food It never climbs head-downwards like the nuthatch (*q v*). Inconspicuous in its upper plumage of brown mottled with white, buff and tawny—for the silvery white of its underparts is not usually visible—the tree-creeper is more common than the incurious suppose; though a shy singer, its song is loud and sweet The nest is placed behind a half-detached piece of bark and a mass of material is used to give a sure foundation for the tiny cup, in which are laid from six to nine eggs of a translucent white, spotted or blotched with rust-colour.

The tree-creeper inhabits almost the whole of Europe as well as Algeria and has been traced across Asia to Japan It is an inhabitant of the greater part of North America. On the European continent a second species, *C brachydactyla,* is found. This is hardly to be distinguished from *C. familiaris* in appearance but has a quite different song, and lives in gardens and parks rather than in woodland

Allied to the tree-creeper, but without its stiff tail-feathers, is the genus *Tichodroma,* the single member of which is the beautiful wall-creeper (*T muraria*) of the Alps and some other mountainous parts of Europe and Asia. It is occasionally seen in Switzerland, fluttering up the face of a rock, conspicuous from the scarlet-crimson of its wing-coverts and its white spotted primaries Its bright hue is hardly visible when the bird is at rest, and it then presents a dingy appearance of grey and black. It is a species of wide range, extending from Spain to China.

The passerine family *Certhiidae* contains a number of genera of birds to which the general name "creeper" is applied; they occur in North America, Europe and Asia, the greater part of Africa, and Australia and New Guinea

TREE-CULTS. Primitive man, observing the growth and death of trees, the elasticity of their branches, the sensitiveness and the annual decay and revival of their foliage, anticipated in his own way the tendency of modern science to bridge the gulf between the animal and the vegetable world Sober Greek philosophers (Aristotle, Plutarch) thought that trees had perceptions, passions and reason. The beliefs of primitive man were part of a small stock of fundamental ideas which persist in one form or another over a large portion of the world, and have found a place in the higher religions.

Trees and Human Life.—Numerous popular stories reflect a firmly rooted belief in an intimate connection between a human being and a tree, plant or flower. Sometimes a man's life depends upon the tree and suffers when it withers or is injured, and we encounter the idea of the *external soul,* already found in the Egyptian "Tale of the Two Brothers" of some 3,000 years ago Here one of the brothers leaves his heart on the top of the flower of the acacia and falls dead when it is cut down Sometimes, however, the tree is an *index,* a mysterious token which shows its sympathy with an absent hero by weakening or dying, as the man becomes ill or loses his life These two features easily combine, and represent a mysterious sympathy between tree- and human-life, which, as a matter of fact, frequently manifests itself in recorded beliefs and customs of historical times Thus, sometimes a new-born child is associated with a newly planted tree

with which its life is supposed to be bound up; or, on ceremonial occasions (betrothal, marriage, ascent to the throne), a personal relationship of this kind is instituted by planting trees, upon the fortunes of which the career of the individual depends Sometimes, moreover, boughs or plants are selected and the individual draws omens of life and death from the fate of his or her choice. Again, a man will put himself into relationship with a tree by depositing upon it something which has been in the closest contact with himself (hair, clothing, etc).

The custom of transferring disease or sickness from men to trees is well known Sometimes the hair, nails, clothing, etc, of a sickly person are fixed to a tree, or they are forcibly inserted in a hole in the trunk, or the tree is split and the patient passes through the aperture Where the tree has been thus injured, its recovery and that of the patient are often associated. In India when a man is supposed to be tormented by a demon, ceremonies are performed to provide it with a tree where it will dwell peacefully without molesting the patient so long as the tree is left unharmed Such ideas do not enter, of course, when the rite merely removes the illness, but endangers the health of those who approach the tree Again, sometimes it is believed that man's personality is mystically united with some healthy and sturdy tree, and in this case we may often presume that such trees already possessed some appropriate reputation Again hair, nail-clippings, etc, are hung upon a tree for safety's sake lest they fall into the hands of an enemy

Spirits in Trees.—Among the Arabs the sacred trees are haunted by angels or by *jinn;* sacrifices are made, and the sick who sleep beneath them receive prescriptions Here, as frequently elsewhere, it is dangerous to pull a bough This dread of damaging special trees is familiar. Cato instructed the woodman to sacrifice to the male or female deity before thinning a grove (*De re rustica,* 139), while in the Homeric poem to Aphrodite the tree nymph is wounded when the tree is injured, and dies when the trunk falls Early Buddhism decided that trees had neither mind nor feeling and might lawfully be cut, but it recognized that certain spirits might reside in them, and this the modern natives of India firmly believe. Propitiation is made before the sacrilegious axe is laid to the holy trees; loss of life or of wealth and the failure of rain are feared should they be wantonly cut; and there are even trees which it is dangerous to climb The Talein of Burma prays to the tree before he cuts it down, and the African woodman will place a fresh sprig upon the stump as a new home for the spirit. In the Gold Coast the silk-cotton and odum (poison) trees are especially sacred as the abode of the two deities, who are honoured by sacrifices—even of human victims, these can be felled only after certain purificatory ceremonies. In general, sacred trees must not be injured unless they (*i e*, their spirits) have been appeased, or means taken to provide the occupant with another abode That the difference between the sacred *object* and the sacred *occupant* was not always clearly drawn is quite intelligible from those beliefs of much less rudimentary religions which confuse the unessential with the essential.

Forms of Cult.—Often the tree is famous for oracles One of the best known is the oak of Dodona tended by priests who slept on the ground. The tall oaks of the old Prussians were inhabited by gods who gave responses, and the old Hebrews had their "terebinth of the teacher" (Gen. xii 6), and "terebinth of the diviners" (Judg ix 37) Sacred trees are also the object of pilgrimage, one of the most noteworthy being the branch of the Bo tree at Ceylon brought thither before the Christian era Again, tree-spirits will hold sway over the surrounding forest or district, and the animals in the locality are sacred and must not be harmed Thus, the pigeons at the grove of Dodona, and the beasts around the north European tree-sanctuaries, were left untouched, even as the modern Dyak allows no interference with the snake by the side of the bush which enshrines a dead kinsman. Sacred fires burned before the Lithuanian Perkuno and the Roman Jupiter; both deities were closely associated with the oak, and, indeed, according to Frazer, the oak seems to have been very commonly used for the perpetual holy fires of the Aryans

The powers of the tree-deities, though often specially connected with the elements, are not necessarily so restricted, and the sacred trees can form the centre of religious, and sometimes, also, of national life. Such deities are not abstract beings, but are potent and immediate, and the cultus is primarily as utilitarian as the duties of life itself. They may have their proper ministrants: the chief sanctuary of the old Prussians was a holy oak around which lived priests and a high priest known as "God's mouth"; in Africa there are sacred groves into which the priest alone may enter, and among the Kissil-Bashi (or Kizilbashes) of the Upper Tigris and Euphrates, the holy tree of the village stands in an enclosure to which only the father-priest has access The trees may be the scene of religious festivals and of periodical fairs and markets Among the Lousiade group in British New Guinea the religious feasts are held under the sacred tree and a portion is laid aside for the spirit-occupants That the invisible spirit naturally enjoyed only the *spiritual* part of the offerings is a belief which has been shared by others than the African negro (Tylor ii. 216). Human sacrifice is known on the Slave Coast and in the Punjab, it was practised among the Druids, and at Odin's grave at Uppsala It is also said that the pollution of old Prussian sacred groves and springs by the intrusion of Christians was atoned for by human victims

Development of Ideas.—As ideas advanced, the spirits associated with trees were represented by posts, idols, or masks, altars were added, and the trunk was roughly shaped to represent the superhuman occupant There is reason to believe that the last-mentioned transformation has frequently happened in the development of iconography Indeed, the natives of the Antilles suppose that certain trees instructed sorcerers to shape their trunks into idols, and to instal them in temple-huts where they could be worshipped and could inspire their priests with oracles When the tree-spirit was conceived to be of human shape the numerous stories which associate trees with men or deities of flesh and blood would easily arise; and just as Indian natives have gods which are supposed to dwell in trees, so in higher religions we find a Zeus or a Dionysus *Endendros,* gods, "occupants of trees," who have been identified with one or other of the leading members of a recognized pantheon Syrian writers speak of a "king of the forest" and of a tall olive tree to the worship of which Satan seduced the people But these "trees of the demons" were hewn down by zealous Syrian Christians So also the caliph Omar cut down the tree at Hodaibaya visited by pilgrims, lest it should be worshipped, and the Council of Nantes (A D 895) expressly enjoined the destruction of trees which were consecrated to demons

Tradition has preserved some recollections of the overthrow of tree-cult in Europe. Bonifacius destroyed the great oak of Jupiter at Geismar in Hesse, and built of the wood a chapel to St Peter (A similar continuity was maintained near Hebron when Constantine destroyed the idols and altars beneath the oak or terebinth of Abraham at Mamre and replaced them by a basilica) On the Heinzenberg near Zell the Chapel of Our Lady stands where the old tree uttered its complaint as the woodman cut it down, and at Kildare (*cilldara,* church of the oak), "Saint" Brigit or Bridget built her church under an oak tree On the other hand, at Samosata, the sacred tree worshipped in Christian times was honoured as the wood of Christ's cross, and this growth of a new tradition to justify or at least to modify an old survival recurs in Palestine where the holy trees, whether adjoining a venerated tomb or not, are often connected with the names of saints or prophets and sometimes with appropriate traditions.

Mannhardt, *Der Baumkultus der Germanen und ihrer Nachbarstamme* (1875), *Antike Wald- und Feldkulte* (1877), W Robertson Smith, *Rel. of the Semites* (3rd ed, index); and, for an introductory study, Mrs. J. H. Philpot, *The Sacred Tree, or the Tree in Religion and Myth* (1897).

TREE-FERN. In old and well-grown specimens of some of the familiar ferns of temperate climates the wide-spreading crown of fronds may be observed to rise at a distance often of a good many inches above the ground, and from a stem of considerable thickness. The male fern *Dryopteris Filix-mas* affords the commonest instance of this, higher and thicker trunks are, however,

occasionally presented by the royal fern (*Osmunda regalis*), in which a height of 2 ft. may be attained, and this with very considerable apparent thickness, due, however, to the origin and descent of a new series of adventitious roots from the bases of each annual set of fronds Some tropical members and allies of these genera become more distinctly tree-like, *e.g.*, *Todea*. *Oleandra* is branched and shrub-like, while *Angiopteris* and *Marattia* may also rise to 2 ft or more. But the tree-ferns proper are practically included within the family Cyatheaceae. This includes seven genera (*Cyathea, Alsophila, Hemitelia, Dicksonia, Thyrsopteris, Cibotium* and *Balantium*) and about 360 species, of which a few are herbaceous, but the majority arboreal and palm-like. reaching frequently a height of 50 ft. or more, *Alsophila excelsa* of Norfolk island having sometimes measured 60 to 80 ft The fronds are rarely simple or simply pinnate, but usually tripinnate or decompound, and may attain a length of 20 ft., thus forming a splendid crown of foliage.

The genera are of wide geographical range, mostly within the tropics; but South Australia, New Zealand, and the southern Pacific islands all possess their tree-ferns In Tasmania *Alsophila australis* has been found up to the snow-level, and in the humid and mountainous regions of the tropics tree-ferns are also found to range up to a considerable altitude The fronds may either contribute to the apparent thickness of the stem by leaving more or less of their bases, which become hardened and persistent, or they may be articulated to the stem and fall off, leaving characteristic scars in spiral series upon the stem The stem is frequently much increased in apparent thickness by the downgrowth of aerial roots, forming a black coating several inches or even a foot in thickness, but its essential structure differs little in principle from that familiar in the rhizome of the common bracken (*Pteris*).

Tree-ferns are cultivated for their beauty alone, a few, however, are of some economic applications, chiefly as sources of starch. Thus the beautiful *Alsophila excelsa* of Norfolk island is said to be threatened with extinction for the sake of its sago-like pith *Cyathea medullaris* also furnishes a kind of sago to the natives of New Zealand, Queensland and the Pacific islands The long silky or rather woolly hairs, so abundant on the stem and frond-leaves in the various species of *Cibotium* have not only been used as a styptic, but in the Sandwich islands furnish wool for stuffing mattresses and cushions

TREE-FROG. Many groups of tailless Amphibia (*see* FROG) are adapted to arboreal life, which is indicated by adhesive discs on the tips of the fingers and toes These discs adhere by rapid and intense pressure of the distal phalanx and special muscles upon the lower surface, which is also provided with glands producing a sticky secretion

The best-known European tree-frog is the little *Hyla arborea*, often kept in glass cylinders, with a ladder which it is supposed to ascend or descend according to the coming weather This frog rarely reaches 2in in length, its upper parts are smooth and shiny, normally of a bright grass-green, which may change rapidly to yellow, brown, olive, or black, some specimens lack the yellow pigment which contributes to form the green colour, and are sky-blue or turquoise blue, the lower parts are white. The commonest American species is *H versicolor*, green, grey, or brown, with a loud piping voice Tree-frogs in U S A are often called tree-toads

The family *Hylidae* is related to the *Bufonidae* or toads, being distinguished by the presence of teeth in the upper jaw and by the claw-like shape of the terminal phalanx of the digits It is a large family, with about 300 species, 250 of which belong to the genus *Hyla*, distributed over Europe, temperate Asia, North Africa, North and South America, Papua, and Australia. *Nototrema* of Central and South America, in the female, develops a broad dorsal pouch in which the young undergo their metamorphoses. *Phyllomedusa*, also from Central and South America, is quadrumanous, the inner finger and the toe being opposable to the others, and the foot being very similar to the hand These frogs deposit their spawn between the leaves of branches overhanging water, into which the tadpoles drop and spend their larval life

TREE KANGAROO, the name of certain arboreal marsupials, forming the genus *Dendrolagus* (*see* MARSUPIALIA) Three species are inhabitants of New Guinea and the fourth, Lumholtz's tree kangaroo (*D lumholtzi*), is found in North Queensland, in dense scrub high up on the mountains. They are arboreal in their habits and feed on bark, leaves, and fruit Their hinder limbs are shorter than in the true kangaroos and their fore limbs longer and more robust, with strong curved and pointed claws. The flesh of the Queensland species is much prized by the natives.

TREE MARRIAGE. In Chota Nagpur, the tribes who speak languages of the Munda group, and in Bengal, low castes such as the Rautias, Bagdis and Murmis, perform the rite of tree marriage as an integral part of the marriage service The nuptial pair are fastened to trees by thread The trees selected are either the *mahua* or the *mango*, the two most important and conspicuous trees in that area In the marriage rites for a number of castes in Mysore, whose language is Dravidian, the marriage is celebrated in a booth, one of the posts of which is called the milk post. This, so we are told, is to secure the continuity of the line, and it has to be cut by the maternal uncle—the male representative of an important social grouping A fig tree is here specified, while in parts of the Punjab, a branch of a jhand tree *Prosopis spicigera* is essential to the due performance of the marriage rites. Quite obviously, trees of such economic importance as the *mahua*, the *mango*, the *jhand* and the fig are selected as conspicuously, essentially fertile, but it is not a general fertility, but a specific fertility, that must be looked for as the reason for their selection They are associated with the beliefs of the people as to the fate of those who are destined or desired to return and be re-born In general, too, trees, notably the *peepul*, are in India associated with the spirits, and for this reason barren women walk round them in order that they may be fertilized by a spirit denizen of the tree In West Africa "nearly all Yoruba believe that souls about to be born live in or among trees, and it is for this reason that women so often pray to the tree spirits to send them children" (P A Talbot, *The Peoples of Southern Nigeria*, vol ii, p. 267)

There are cases where tree marriage affords a means of attaining the social status of marriage, as where a bachelor who seeks to marry a widow is obliged to marry a tree, which is then cut down He is then a widower, equal in status with his human bride It may be a substitute and intended to avoid the curse of widowhood, or to confer the status of married woman on a girl, and thus escape the social and religious penalties attaching to those whose daughters do not marry Lastly, there is the common practice in India of marrying a newly-constructed tank to a plantain tree for the purpose of blessing the tank

Tree marriage is part of a series of rites by means of which the continuity of the group life is secured

TREE PLANTING. The quality of the soil in which trees are planted exerts a considerable influence upon their development, but, given the best possible soil conditions they may fail through indifferent planting Where the soil is naturally deep and good, planting operations are less burdensome than in places where the soil is poor, but even then there are conditions that must be observed if the most satisfactory results are to be obtained Generally, the larger the trees to be planted, the greater should be the preparatory work and the greater the care in planting

If the natural water level in wet weather is within two feet of the surface of the ground some system of drainage should be adopted, otherwise the lower roots of the trees may be killed, particularly where the soil is heavy or of a clayey nature The quality of the subsoil should also be observed, for although there may be a depth of 12 or 15 in of good surface soil, a hard impervious pan of gravel or other material beneath is sufficient to check effectively the tree's growth Trees cultivated in nurseries are grown in well worked ground, and it is necessary to provide root conditions as nearly similar as possible to those existing in the nursery when they are transferred to permanent places All ground required for ornamental trees should be trenched to a depth of 2 to 3 ft. Where trenching over a wide area cannot be done, large holes should be dug When the natural soil is of good quality, holes 3 to 4 ft in diameter are large enough for small trees, but where the soil is poor, much wider holes are necessary. For

important trees, holes 6, 8 or 10 ft. across may be desirable. For the largest growing trees they should be made 3 ft. deep, for those of smaller size, 2 to 2½ ft In all cases it is advisable to break up the bottom, particularly if it is very hard During the digging, all the best of the soil should be saved, and the remainder substituted by the best soil obtainable It is not wise to use manure in the holes and if any is included in the filling it should be so placed that it will not come into contact with the roots of the trees As soon as the holes have been dug they should be refilled to within 9 in of the surface, care being taken, as the work proceeds, to tread or ram the soil firm Where possible, water may be run into the holes to help to firm the ground Planting should not take place for two or three weeks after the holes have been partially filled or until such time as the soil has settled into position; but should hurried planting be necessary, the lower soil must be well rammed or trodden before the trees are placed in position. Deep planting must be avoided, it is the cause of ill health and premature death of many trees Care must be taken to see that the upper roots are kept near the surface of the ground. A rod placed across the hole, at the natural level of the ground, proves a good guide; 1 in of soil placed above the top roots is usually sufficient Tree planting is two men's work; one man should hold the tree in position whilst the other fills in the soil and firms it about the roots. When placing a tree in position, spread the roots out to their widest extent and work fine soil amongst them. The soil may be made firm about the roots by means of a rammer or by well treading. On the completion of the work, a good watering will help to settle the soil

Some trees require staking after planting, the stakes being retained until the roots have become vigorous again The stakes must be driven well into the ground, but care must be taken not to pierce the roots A piece of rubber or textile material should be placed around the trunk in order to prevent the string from cutting the bark The string should be given a turn around the stake to prevent it slipping and the work completed by a secure tie. Several ties may be needed for a single tree. In the case of large trees it may be desirable to use a triangle of soft ropes secured to the trunk 5 or 6 ft from the ground and to short stakes driven into the ground 3 ft or so from the tree. Open ground should be maintained about the bases of young trees for a number of years, or until they are making vigorous growth, and only then should grass be allowed to grow close to the trunks. During dry weather, in the early years after planting, assistance may be given by applying a mulch of decayed manure and leaves to the ground above the roots, and should the leaves flag or begin to turn yellow, water should be provided Evergreen trees are usually more difficult to re-establish after transplanting than deciduous trees It is wise to remove some of the branches of evergreens at the time of transplanting in order to relieve the strain upon the injured roots, and it is better to carry out the work during late spring or early autumn than in winter If they are moved without soil more satisfactory results are obtained by transplanting them during September or early May Evergreens that are moved with considerable balls of soil attached to the roots may be transplanted during the winter Deciduous trees may be transplanted from October to March. Should the leaves of transplanted evergreens fall, no alarm need be felt; that is one of nature's ways of restoring the balance between injured roots and branches; if, however, the leaves wither and remain on the branches, recovery is not progressing and it will be necessary to cut the branches back to relieve the strain upon the roots Although trees are usually transplanted when comparatively young and small, it is possible to transfer well grown trees from place to place. By means of machinery, trees 30 to 40 ft. high, with a mass of earth attached to the roots, are often transplanted with excellent results. Such trees should be carefully watered during dry weather. (*See* also Arboriculture) (W. D)

TREE-SHREW, any of the arboreal insectivorous mammals of the genus *Tupaia.* There are about a dozen species, widely distributed over the east. It is held by many anatomists that forms of this type gave rise to the Primates (*q.v*) (*See* Insectivora)

TREE-TOAD: *see* Tree-Frog.

TRÉGUIER, a port of western France, in the department of Côtes-du-Nord, 36 m. N W. of St Brieuc by road. Pop. (1926), 2,494 Tréguier (*Trecorum*), which dates from the 6th century, grew up round a monastery founded by St Tugdual. In the 9th century it became the seat of a bishopric, suppressed in 1790. The port is situated about 5½ m from the English Channel at the confluence of two streams that form the Tréguier river; it carries on fishing and a coasting and small foreign trade The cathedral (14th and 15th centuries), has three towers over the transept, one of which is surmounted by a fine spire, and a 15th century cloister Ernest Renan was a native of the town

TREILHARD, JEAN BAPTISTE (1742–1810), French revolutionary, was born at Brives (Corrèze). In Paris he gained reputation as an avocat at the parlement. He was elected to the Constituent Assembly where he showed great capacity in dealing with the reorganization of the Church and the nationalization of ecclesiastical property Ineligible, as a member of the Constituent Assembly, for the Legislative Assembly, he became president of the criminal tribunal of Paris In the Convention he joined the Mountain; he was a member of the committee of public safety, and became president of the Convention on Dec. 27, 1792. Under the Directory he entered the Council of the Five Hundred (of which he was president during the month of Nivose, year IV), was a member of the Tribunal of Cassation, plenipotentiary at the Congress of Rastatt, and became a director in the year VI. After the *coup d'état* of 18 Brumaire he became president of the tribunal of appeal and councillor of State. He took an important part in drafting the civil code, the criminal code, the code of civil procedure and the commercial code He died on Dec 1, 1810, a senator and count of the empire.

See Guyot d'Amfreville, *Vie de J. B. Treilhard* (Limoges, 1879); Bonnal de Ganges, "Représentants du peuple dignitaires par Napoléon . . . Treilhard," in the *Revue du monde catholique* (7th series, vol. iii., 1900).

TREITSCHKE, HEINRICH VON (1834–1896), German historian and political writer, the son of a Saxon officer, was born at Dresden on Sept 15, 1834. Prevented by deafness from entering the public service, he studied at Leipzig and Bonn, where he was a pupil of Dahlmann. He established himself as a *Privatdozent* at Leipzig, lecturing on history and politics, and at once became very popular with the students, but his political opinions made it impossible for the Saxon government to appoint him to a professorship. He was at that time a strong Liberal; he hoped to see Germany united into a single state with a parliamentary government, and that all the smaller states would be swept away. In 1863 he was appointed professor at Freiburg, in 1866, at the outbreak of war, he showed his Prussian sympathies by removing to Berlin, became a Prussian subject, and was appointed editor of the *Preussische Jahrbücher.* After holding appointments at Kiel and Heidelberg, he was in 1874 made professor at Berlin; he had already in 1871 become a member of the Reichstag, and from that time till his death in 1896 he was one of the most prominent figures in the city. On Sybel's death he succeeded him as editor of the *Historische Zeitschrift.* He had outgrown his early Liberalism and become the chief panegyrist of the house of Hohenzollern.

Treitschke did more than any one to mould the minds of the rising generation, and he carried them with him even in his violent attacks on all opinions and all parties which appeared in any way to be injurious to the rising power of Germany He supported the government in its attempts to subdue by legislation the Socialists, Poles and Catholics; and he was one of the few men of eminence who gave the sanction of his name to the attacks on the Jews which began in 1878. As a strong advocate of colonial expansion he was a bitter enemy of Great Britain, and he was to a large extent responsible for the anti-British feeling of German Chauvinism during the last years of the 19th century. In the Reichstag he had originally been a member of the National Liberal party, but in 1879 he was the first to accept the new commercial policy of Bismarck, and in his later years he joined the Moderate Conservatives. He died at Berlin on April 28, 1896.

As an historian Treitschke confined himself to those periods

and characters in which great political problems were being worked out: above all, he was a patriotic historian, and he never wandered far from Prussia His great achievement was the *History of Germany in the Nineteenth Century* (Eng. trans. by E. and C. Paul, 7 vols., 1915–19). The first volume was published in 1879, and during the next sixteen years four more volumes appeared, but at his death he had only advanced to the year 1847.

The most important of the essays were collected under the title *Historische und politische Aufsätze* (4 vols., Leipzig, 1896); a selection from his more controversial writings was made under the title *Zehn Jahre deutscher Kampfe*; in 1896 a new volume appeared, called *Deutsche Kämpfe, neue Folge* After his death his lectures on political subjects were published under the title *Politik* (Eng. trans, 2 vols., 1916). He brought out also in 1856 a short volume of poems called *Vaterländische Gedichte*, and another volume in the following year His *Briefe*, ed. M. Cornicelius (3 vols., Berlin, 1859–96), were reprinted at Leipzig (1913–20).

See Schiemann, *Heinrich v. Treitschkes Lehr- und Wander-jahre, 1836–1866* (Munich, 1896); *Gustav Freitag und Heinrich v. Treitschke im Briefwechsel* (Leipzig, 1900); A. Hausrath, *Leben von Heinrich von Treitschke* (Eng. trans., with extracts from Treitschke's works, 1914), E. Barker, *Nietzsche und Treitschke* (1914); H. W. C. Davies, *The Political Thought of Heinrich von Treitschke* (1914); W. Rittinghaus, *Die Kunst der Geschichtschreibung Heinrich von Treitschkes* (1914); C. S. Terry, *Treitschke, Bernhardi and Some Theologians* (1915); L Lorenz, *Treitschke in unsere Zeit* (1916).

TRELAWNY, EDWARD JOHN (1792–1881), English sailor and friend of Shelley and Byron, was born in London on Nov 13, 1792, the son of an army officer After a short term in the navy and a naval school, he shipped for India, but deserted at Bombay. For several years he led an adventurous life in India, but about 1813 returned to England, married and settled down Early in 1822 he met Shelley and Byron at Pisa, and passed nearly every day with one or both of them until the drowning of Shelley (*q v*) and Williams on July 8 He superintended the recovery and cremation of the bodies, snatching Shelley's heart from the flames He added the lines from the *Tempest* to Leigh Hunt's "Cor Cordium", and, finally, he supplied the funds for Mrs. Shelley's return to England In 1823 he set out with Byron for Greece, to aid in the struggle for independence. Distressed by his companion's dilatoriness, Trelawny left him and joined the insurgent chief Odysseus and afterwards married his sister Tersitza While in charge of the former's fortress on Parnassus he was assaulted by two Englishmen and nearly killed Returning to England, he lived for a time in Cornwall with his mother and afterwards in London, where he became a great social favourite Permission having been refused him to write the life of Shelley, he began an account of his own life in the *Adventures of a Younger Son* (1835; new ed. by E. C Mayne, 1925), followed much later by a second part· *Recollections of Shelley and Byron* (1858), which was recast as *Records of Shelley, Byron and the Author* in 1878 (new ed by E Dowden 1906) This gives an admirable portrait of Shelley, and a less truthful one of Byron He married a third time, but the irregularity of his life estranged him from his wife. He died at Sompting, near Worthing, on Aug 13, 1881 The old seaman in Millais's picture, "The North-West Passage," in the Tate gallery, London, gives a portrait of him

See the *Letters of Edward J. Trelawny*, edited with Introduction by H. Buxton Forman, C.B. (1910).

TRELAWNY, SIR JONATHAN, Bart. (1650–1721), English prelate, was a younger son of Sir Jonathan Trelawny, bart. (1624–1685), and was born at Pelynt, Cornwall, on March 24, 1650. Educated at Westminster School and at Christ Church, Oxford, Trelawny took holy orders in 1673. His service to James II. during Monmouth's rebellion, was rewarded (Nov. 8, 1685) with the bishopric of Bristol He was loyal to King James until the first declaration of indulgence in April 1687, when, as a bishop, he used his influence with his clergy against the king, and, as a Cornish landowner, resisted the attempt to assemble a packed parliament. In May 1688 Trelawny signed the petition against the second declaration of indulgence, and in the following month was imprisoned in the Tower of London with Sancroft and five other bishops, sharing their triumphant acquittal. In spite of Burnet's assertion, it is probable that Trelawny did not sign the invitation to William of Orange, although he certainly welcomed his army into Bristol. James II. had nominated him to the see of Exeter, and the appointment was almost at once confirmed by William III. Trelawny took the oaths of allegiance to William and Mary; but he was soon estranged from the new king and sided with the princess Anne, who showed him some favour after she became queen. In 1707 Trelawny was appointed bishop of Winchester and became prelate of the Order of the Garter, but henceforward he took very little part in politics. He died at his residence at Chelsea on July 19, 1721, and was buried at Pelynt Trelawny is the hero, or one of the heroes, of the refrain of R. S. Hawker's (modern) ballad.

"And shall Trelawny die,
Here's twenty thousand Cornishmen
Will know the reason why."

TRELEASE, WILLIAM (1857–), American botanist, was born at Mt Vernon, N Y., on Feb. 22, 1857. He graduated at Cornell university in 1880 and continued botanical study at Harvard university (Sc D, 1884). He was professor of botany at the University of Wisconsin from 1883 to 1885 and at Washington university, St Louis, Mo, from 1885 to 1912 and director of the Missouri Botanical Garden in 1889–1912 In 1913–26 he was professor of botany in the University of Illinois

He edited (with Asa Gray) *The Botanical Works of George Engelmann* and translated Poulsen's *Botanical Microchemistry* and Salomonsen's *Bacteriological Technology* He wrote *Agave in the West Indies* (1913), *The Genus Phoradendron* (1916), *Plants Materials of Decorative Gardening* (1917), *Winter Botany* (1918). *The American Oaks* (1925) and numerous papers on botany and entomology. (*See* Botanical Garden)

TREMATODES (flukes), a class of Platyhelminthes (*q.v.*) in which the body is unsegmented and without a cellular epidermis or external cilia, and an alimentary canal is present. All the members of the group are parasitic

General Morphology.—The body is generally flattened and leaf-like or ribbon-like in shape, but may be relatively stout and oval or circular in transverse section One or more muscular suckers are usually present on the ventral surface. In general structure the Trematodes closely resemble the free-living Turbellaria (*q v.*) They differ from them in the development of suckers and other organs for attachment to the host, and in the absence (in the adult) of a ciliated epidermis

The external covering is a stout cuticle, often armed with spines, below which is a subcuticular layer containing unicellular glands The number and arrangement of the suckers are very variable Usually there is an anterior sucker or pair of suckers, and a posterior sucker, or a posterior disc-like organ of attachment provided with subsidiary suckers or with chitinoid hooks of various kinds The complex development of the posterior organ of attachment is characteristic of the ectoparasitic forms (Monogenea). In endoparasitic forms (Digenea) the posterior sucker is usually a simple muscular disc or cup, and may be situated at the posterior end of the body, but is more often displaced anteriorly so as to lie in front of the middle or even close behind the oral sucker.

Pigment is rare in Trematodes, but occurs in the parenchyma of certain species, more especially among the Monogenea The body of endoparasitic species may, however, appear more or less brightly coloured on account of the contents of the intestine and uterus, and the vitelline glands, showing by transparency

The musculature usually consists of an outer circular and an inner longitudinal layer of fibres. Oblique and dorso-ventral fibres are also frequently present.

Except in one family, the mouth is situated at or near the anterior extremity It may open through an anterior, or oral, sucker, or, in certain ectoparasitic forms, may be flanked by a pair of adoral suckers. The alimentary canal may be a simple, blind sac, but usually consists of a relatively short median anterior portion and two posterior branches arising by the bifurcation of the former These branches may be simple or secondarily branched, and may join again posteriorly, or may remain distinct.

In the great majority of forms they are without any posterior opening, but in one or two species they have been found to open to the exterior by one or a pair of pores The median anterior portion of the gut may be differentiated into a muscular sucking

FIG. 1—FASCIOLA HEPATICA, SHOWING FROM ABOVE DOWNWARDS, VENTRAL ASPECT, ANTERIOR PORTION MORE HIGHLY MAGNIFIED, GENITAL SINUS AND OTHER PARTS, FLAME CELL FROM EXCRETORY APPARATUS, EGG

bulb, or pharynx, and a simple tubular portion between this and the bifurcation, called the oesophagus.

The whole of the space between the wall of the alimentary canal and the external cuticle is filled up with a spongy connective tissue, or parenchyma, in which the other organs are embedded, as in other classes of Platyhelminthes. The nervous system consists of a pair of central ganglionic masses (the "brain"), situated anteriorly and dorsally, and longitudinal nerve-cords (of which there may be as many as four pairs) running posteriorly throughout the body, and connected at intervals by transverse commissures. Eyes are present in some of the ectoparasitic forms, and in the larval stages of some endoparasitic species, but are absent in the adults of the latter There may also be "tactile cones" on the surface of the cuticle, consisting of small elevations surmounted by groups of stiff cilia.

The excretory system is composed, as in other Platyhelminthes, of branching canals whose smallest branches end in flame-cells. There are usually two main longitudinal canals, which may open independently, through a pair of excretory sacs, on to the dorsal surface, or may lead into a common posterior "bladder."

With few exceptions, the Trematodes are hermaphrodite. The complex system of genital organs is arranged on the same general plan as in other groups of Platyhelminthes, but is subject to much variation in details, and is of great importance from the taxonomic standpoint The testes are almost invariably paired, and are usually compact organs, though they may be deeply lobate or even elaborately branched. The male ducts unite and open through a muscular intromittent organ, or cirrus, which is usually contained in a special pouch (the cirrus-sac). The ovary is single, and, like the testes, may be compact or more or less branched The vitellaria generally consist of two lateral series of follicles, those of each side being connected by branching ducts with a main yolk-duct, and the two main ducts crossing the body to join in the median region, near the shell-gland

In ectoparasitic forms there is a vagina, opening to the exterior by a pore quite distinct from that of the uterus, or there may be a pair of such structures The uterus, in the Trematodes, is a continuation of the oviduct, and is a more or less convoluted tube usually opening side by side with the male duct, often into a common atrium In forms without a separate vagina it functions as a fertilization canal as well as a reservoir for eggs and a duct for their expulsion In some of the ectoparasitic Trematodes a "genito-intestinal canal" connects the oviduct with the intestine. In the endoparasitic forms (Digenea) this connection is lost, but a duct, known as Laurer's canal, springing from the oviduct and either opening on the surface of the body or ending blindly below the skin, is usually present The eggs, after being fertilized and supplied with yolk, are enclosed in a chitinoid shell of variable form, sometimes stalked or with terminal filaments, and very commonly provided with an operculum at one end

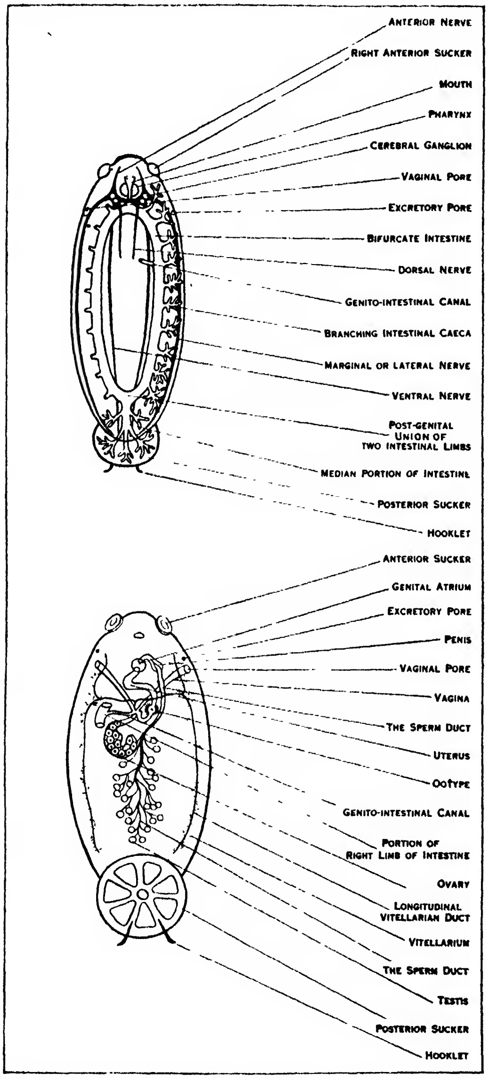
Classification.—The division of the class Trematoda into two orders, Monogenea and Digenea, proposed by van Beneden in 1858, is still accepted by modern authorities. These orders represent two well marked groups differing fundamentally in structure, habits and life-history

The order Monogenea comprises forms of almost exclusively ectoparasitic habit, without an alternation of generations in their life-history, and having the following structural peculiarities, among others The mouth is simple and is not surrounded by an oral sucker, though paired accessory suckers may be present in its neighbourhood. The posterior sucker may be single (but in this case is usually of complex structure and often provided with accessory chitinoid organs of attachment) or there may be a number of paired posterior suckers, which also have chitinoid armatures There is a vagina, or a pair of vaginae, distinct from the uterus, and there are usually paired excretory pores situated dorsally near the anterior end of the body.

These forms live mainly on the external surface or on the gills of fishes and other cold-blooded aquatic animals, and feed on mucus and other matter, or occasionally on the blood of the host. The order includes 13 families, among which are the Tristomatidae, Gyrodactylidae, Polystomatidae and Octocotylidae.

The order Digenea includes all the forms which live as endoparasites within the bodies of other animals. These have a complex life-history involving an alternation between a sexual phase and an asexual or parthenogenetic phase of multiplication. They have an oral sucker surrounding the mouth, and usually a posterior sucker which is a simple muscular organ without chitinoid armature There is no vagina, as distinct from the uterus, and the excretory pore is usually single and posterior. The adult forms occur in all classes of vertebrates, the larval forms in both vertebrates and invertebrates.

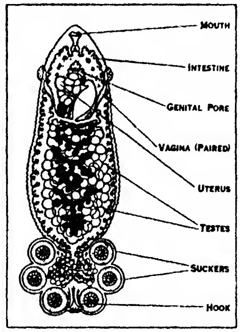
The suborder Gasterostomata includes a single family (Bucephalidae), in which the mouth is placed towards the middle of the ventral surface. All the other families (of which there are about 60) are placed in a second suborder, Prosostomata, in which the mouth occupies its normal anterior position The great majority of the forms in this suborder are placed in the



AFTER LANKESTER, "TREATISE ON ZOOLOGY" (A & C BLACK)

FIG. 2—SCHEMATIC FIGURE OF A MONOGENETIC TREMATODE, ILLUSTRATING STRUCTURE (AFTER BENHAM)

tribe Fascioloidae, and have a general resemblance in form to the well known liver-fluke (*Fasciola*). Among the best known families may be mentioned the Fasciolidae, Dicrocoeliidae, Lepodermatidae, Opisthorchidae, Cyclocoelidae (Monostomidae), Echinostomatidae, Schistosomatidae and Paramphistomidae. The remarkable genus *Aspidogaster*, parasitic in molluscs, differs from all other Prosostomata in the form of the posterior sucker, which occupies the greater part of the ventral surface, and is divided up into a number of partitions It was formerly placed in a separate order, but is regarded by Poche as forming a tribe, Aspidogastroidae of the Prosostomata

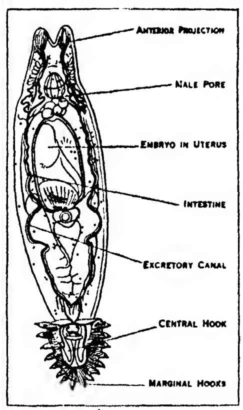


FROM "ZEITSCHRIFT FUR WISSENSCHAFTLICHE ZOOLOGIE" (ENGELMANN)

FIG 3—VENTRAL VIEW OF POLYSTOMUM INTEGERRIMUM (AFTER ZELLER)

Development and Life-histories.—The eggs of the Monogenea are either deposited in water or attached to the host by means of stalk-like processes. In some cases (*Gyrodactylus*, a parasite of the gills of minnows and other fishes) but a single egg is produced at a time, and this develops within the body of the parent into an embryo, within which another embryo is formed before its birth There may be a ciliated free-swimming larval stage, as in *Polystomum* (a form inhabiting the bladder of frogs and toads) The larva of this form invades the gill-chamber of tadpoles, and migrates by way of the alimentary canal to its definitive habitat *Diplozoon* (found on the skin of the minnow) also has a free-swimming stage, and is remarkable for the fact that two larvae (called *Diporpae*) unite, each holding the other by its ventral sucker, and fuse into a single X-shaped organism, the two original sets of genitalia becoming permanently interconnected In other cases there appears to be no free-swimming stage, and the larvae hatching from the eggs develop directly into the adult form

In the Digenea the development is indirect, and may involve one or more changes of host, and sometimes a free-swimming stage The life-history of the liver-fluke of the sheep and other animals may be taken as typical. This form, as an adult fluke, inhabits the bile-ducts of the vertebrate host The eggs are passed out of the host's body with the faeces, and hatch in a short time in the open if the conditions of moisture and temperature are suitable The embryo, on escaping from the egg, is a ciliated organism known as a *miracidium*, provided with a pair of eye-spots and an anterior boring organ It swims about until it meets with a suitable intermediate host (certain snails—in Europe, *Limnaea truncatula*). Boring its way into this through the skin, it sheds its ciliated coat and penetrates into the internal organs Here it grows into an irregular, sac-like body known as a *sporocyst*. Within this there are formed by budding numerous bodies called *rediae*. The redia has an oral sucker and a sac-like intestine Each redia gives rise, by internal budding, either to a further generation of rediae or to larvae of a different type, called *cercariae*. The cercaria is somewhat tadpole-like, having a broad body and a narrow tail It has two suckers and a bifurcate intestine. The cercaria escapes from the snail and swims or wriggles about in water, finally coming to rest on some solid body, such as a blade of grass, where it loses its tail and secretes



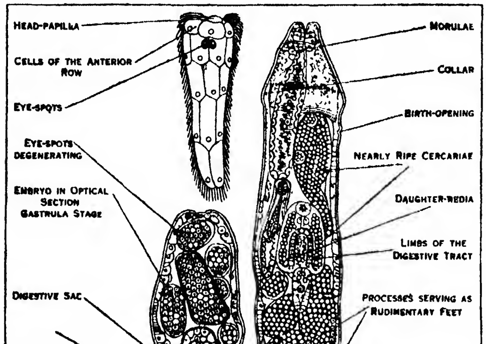
FROM "ARCHIV FÜR ANATOMIE, PHYSIOLOGIE UND WISSENSCHAFTLICHE MEDIZIN (DE GRUYTER & CO)

FIG 4—VENTRAL VIEW OF GYRODACTYLUS ELEGANS (AFTER WAGENER)

round itself a "cyst." Should this be swallowed by a suitable vertebrate animal, the cercaria is liberated from the cyst and migrates into the body-cavity and thence into the liver, where it grows into an adult fluke

An interesting modification of the life-history is found in the genus *Leucochloridium* The sporocyst of this form sends branches into the head and tentacles of its snail host. The branches are brightly coloured and capable of pulsating movements, making the snail conspicuous and particularly liable to the attacks of birds. The transference of the cercariae contained within the snail to suitable final hosts among the birds is thus ensured.

In some genera the cercariae, instead of remaining passive until swallowed, swim about in water and penetrate actively through the skin either of the final or of a second intermediate



FROM THOMAS IN "QUARTERLY JOURNAL OF MICROSCOPICAL SCIENCE" (CLARENDON PRESS)

FIG. 5 —FIVE STAGES IN THE LIFE-HISTORY OF THE LIVER-FLUKE
Above, the miracidium; left centre, a sporocyst containing young rediae; right centre, adult redia containing daughter redia and two almost mature cercariae; left bottom, a young redia; right bottom, a free cercaria (all highly magnified)

host. The fork-tailed cercariae of the blood-flukes (*Schistosoma*) thus attack man and other warm-blooded vertebrates, and the adults inhabit the blood-vessels. The human lung-fluke, *Paragonimus,* leaves its first intermediate host (a mollusc) as a cercaria, and enters certain freshwater crabs and crayfishes, in which it becomes encysted. Human infection, in the Orient, is acquired by eating these animals. Several small flukes belonging to the genera *Opisthorchis, Clonorchis* and *Metagonimus* make use, in a similar manner, of freshwater fishes as second intermediate hosts, the first host being always, so far as is known, a snail.

Economic Importance.—Schistosomiasis (or Bilharziosis) is probably the most important of the human diseases caused by Trematodes In Egypt and many other parts of Africa two species of *Schistosoma, S haematobium* and *S. mansoni,* are prevalent The former also occurs in Asia, certain localities in the south of Europe, and Australia, and the latter in the West Indies and South America In the Far East their place is taken by a third species, *S. japonicum.* These flukes inhabit the mesenteric and portal veins, and their eggs cause obstruction and rupture of the capillaries either in the wall of the bladder or in that of the bowel, with consequent haemorrhage and ulceration.

The common liver-fluke (*Fasciola hepatica*) is an important parasite of sheep, sometimes causing serious and fatal outbreaks of the disease known as "liver-rot." As a human parasite this worm is rare, but certain smaller liver-flukes (*Opisthorchis* and *Clonorchis*) are not uncommon in eastern countries.

The lung-fluke, *Paragonimus westermani,* is a human parasite of some importance in the Far East, and occurs also in South America and Mexico. The various species of flukes which occur in the alimentary canal of man and domestic animals appear to be, on the whole, of relatively little economic significance (H A B)

TREMOLITE, a mineral of the amphibole (*q v*) group, of the composition $CaMg_3(SiO_3)_4$, and crystallizing in the monoclinic system Tremolite (named in 1796 from the Val Tremola, St Gotthard, where it was first found) always contains water in solid solution in amounts varying up to 2 5% and is not prepared from dry melts It is usually developed in fibrous and bladed crystals of white or grey colour Solid solutions of tremolite and the corresponding iron compound, $CaFe_3(SiO_3)_4$, are known as actinolite They are distinguished by their green colour Tremolite is a common mineral of metamorphosed carbonate sediments. Typical examples occur in the dolomite of Campolongo (Tessin) and in limestone at Russell, New York (C E. T.)

TRENCH, FREDERICK HERBERT (1865–1923), Irish poet and playwright, was born at Avoncore, Co. Cork, on Nov. 12, 1865. Educated at Haileybury and at Keble college, Oxford, he was elected a fellow of All Souls' college, and from 1891–1908 was an examiner in the Board of Education This appointment he gave up in 1908 in order to devote himself to literary work. In 1908 he became director of the Haymarket theatre, London, where he staged *King Lear* and Maeterlinck's *Blue Bird.* His first volume of poems, *Deirdre Wedded,* appeared in 1901. It was followed by further poems, notably "Apollo and the Seaman," included in *New Poems* (1907), and *Lyrics and Narrative Poems* (1911). Among his later publications were an *Ode from Italy in Time of War* (1915); *Poems: with Fables in Prose* (1918); and a poetic play *Napoleon* (1919), which was produced in London by the Stage Society in 1919 He died on June 11, 1923. His collected works, edited by H. Williams, were published in 1924, and a volume of selected poems in the same year.

See Abel Chevalley, *Herbert Trench: Notice sur sa Vie et ses Oeuvres* (1925).

TRENCH, RICHARD CHENEVIX (1807–1886), Anglican archbishop and poet, was born at Dublin on Sept. 9, 1807. He was educated at Harrow, and Trinity College, Cambridge. While incumbent of Curdridge Chapel near Bishops Waltham, Hants, he published (1835) *The Story of Justin Martyr and Other Poems*, which was favourably received, and was followed in 1838 by *Sabbation, Honor Neale, and other Poems*, and in 1842 by *Poems from Eastern Sources*. He became rector of Itchenstoke (1845), Hulsean Lecturer (1845–46) and professor of divinity at King's college, London In 1851 he wrote *The Study of Words*, followed by *English Past and Present* (1855) and *A Select Glossary of English Words* (1859) All have gone through numerous editions and have contributed much to promote the historical study of the English tongue His paper, read before the Philological Society "On some Deficiencies in our English Dictionaries" (1857), gave the first impulse to the great Oxford *New English Dictionary* His advocacy of a revised translation of the New Testament (1858) aided to promote another great national undertaking. In 1856 he published a valuable essay on Calderon, with a translation of a portion of *Life is a Dream* in the original metre In 1841 he had published his *Notes on the Parables*, and in 1846 his *Notes on the Miracles*, popular works which are treasuries of erudite and acute illustration

In 1856 Trench was raised to the deanery of Westminster. Here he instituted evening nave services. In January 1864 he was advanced to the more dignified but less congenial post of archbishop of Dublin. He died in London on March 28, 1886.

See his *Letters and Memorials* (2 vols., 1886).

TRENCHARD, SIR HUGH MONTAGUE, 1ST BART, cr. 1919, K C B. 1918 (1873–), British air marshal, was born on Feb. 3, 1873. Commissioned in the Royal Scots Fusiliers in 1893, he served in the South African War with the Imperial Yeomanry and the Canadian Scouts From 1903 to 1910 he served in West Africa In 1912 he qualified as an air pilot and became an instructor at the central flying school at Upavon, where he was appointed assistant commandant the following year. On the outbreak of the World War Trenchard assumed charge at Farnborough, but before the end of 1914 was summoned to France, and became head of the military wing of the Royal Flying Corps. His strong personality, foresight and power of command made his name a household word in France, and with the expansion of the air service he rose from major to major-general in little over a year After the formation of the Royal Air Force he became, in March 1918, chief of the air staff This position he resigned a month later, owing to disagreement with the first air minister, Lord Rothermere But a few weeks later he received command of the newly formed independent air force, whose mission was to raid Germany, a post that gave scope to his gift for inspiring men and to his development of the strategical rôle of aircraft In 1922 he was promoted air chief marshal

TRENCK, FRANZ, FREIHERR VON DER (1711–1749), Austrian soldier, was born on Jan 1, 1711, of a military family Educated by the Jesuits at Sopron (Oldenburg), he entered the Imperial army in 1728 but resigned in disgrace three years later He then married and lived on his estates for some years. Upon the death of his wife in 1737 he offered to raise an irregular corps of "Pandours" against the Turks, but this offer was refused and he then entered the Russian army. But after serving against the Turks for a short time as captain and major of cavalry he was accused of bad conduct, brutality and disobedience, and condemned to death, the sentence being commuted by Field Marshal Münnich to degradation and imprisonment. He returned to Austria, where his father was governor of a small fortress, but there too came into conflict with every one and actually "took sanctuary" in a convent in Vienna But Prince Charles of Lorraine obtained for him an amnesty and a commission in a corps of irregulars, where he rose to be lieutenant-colonel (1743) and colonel (1744). But at the battle of Soor he and his irregulars plundered when they should have been fighting and Trenck was accused (probably falsely) of having allowed the king of Prussia himself to escape. He was court-martialled in Vienna, and condemned to death; but the sentence was commuted by the queen into one of cashiering and imprisonment. The rest of his life was spent in mild captivity in the fortress of Spielberg, where he died on Oct. 4, 1749.

His cousin, FRIEDRICH, FREIHERR VON DER TRENCK (1726–1794), the writer of the celebrated autobiography, was born on Feb 16, 1726, at Königsberg, his father being a Prussian general. He was educated at the University of Konigsberg, entered the Prussian army in 1742 and became an orderly officer on Frederick's own staff. But within a year he fell into disgrace because of a love affair—whether real or imaginary—with the king's sister Princess Amalie, and in 1743 Frederick had him arrested and confined in the fortress of Glatz, whence in 1746 he escaped Making his way home and thence to Vienna, in the vain hope of finding employment under his now disgraced cousin, he finally entered the Russian service On succeeding to the family estates on his cousin's death, he returned to Germany In 1754 he visited Prussia, but was there arrested and confined in Magdeburg for ten years, making frequent attempts, of incredible audacity, to escape. After the close of the Seven Years' War, Maria Theresa requested his release Trenck then spent some years in Aix-la-Chapelle, and eventually returned to his Hungarian estates Here he composed his celebrated autobiography and many other writings, and undertook various diplomatic or secret service missions. He went to Paris in 1791 to witness the Revolution He was denounced as an Austrian spy and guillotined on July 24, 1794

His autobiography first appeared in German at Berlin and Vienna (13 vols) in 1787 Shortly afterwards a French version, by his own hand, was published at Strasbourg His other published works, in eight volumes, appeared shortly after the autobiography at Leipzig. A reprint of the autobiography appeared in 1910 in "Reclam's Universal Series"

See Wahrmann, *Leben und Thaten des Franz, Freiherr von der Trenck* and *Friedrich, Freiherrn von der Trencks Leben, Kerker und Tod* (both published at Leipzig, 1837).

TRENDELENBURG, FRIEDRICH ADOLF (1802–1872), German philosopher and philologist, was born on Nov 30, 1802, at Eutin, near Lübeck He was educated at the universities of Kiel, Leipzig and Berlin He became more and more attracted to the study of Plato and Aristotle, and his doctor's dissertation (1826) was an attempt to reach through Aristotle's criticisms a more accurate knowledge of the Platonic philosophy (*Platonis de ideis et numeris doctrina ex Aristotele illustrata*) He spent seven years as tutor in a private family, occupying his leisure in preparing a critical edition of Aristotle's *De anima* (1833; 2nd ed by C Belger, 1877) In 1833 Altenstein, Prussian minister of education, appointed Trendelenburg extraordinary professor in Berlin, and four years later he was advanced to an ordinary professorship In 1865 he engaged in an acrimonious controversy on the interpretation of Kant's doctrine of Space with Kuno Fischer, whom he attacked in *Kuno Fischer und sein Kant* (1869), which drew forth the reply *Anti-Trendelenburg* (1870) He died on Jan. 24, 1872

Trendelenburg's *Naturrecht* may be taken as in a manner the completion of his system, his working out of the ideal as present in the real The ethical end is taken to be the idea of humanity, not in the abstract as formulated by Kant, but in the context of the State and of history Law is treated throughout as the vehicle of ethical requirements In Trendelenburg's treatment of the State, as the ethical organism in which the individual (the potential man) may be said first to emerge into actuality, we may trace his nurture on the best ideas of Hellenic antiquity

Trendelenburg was also the author of the following: *Elementa logices Aristotelicae* (1836; 9th ed, 1892; Eng trans., 1881), a selection of passages from the *Organon* with Latin translation and notes, containing the substance of Aristotle's logical doctrine, supplemented by *Erlauterungen zu den Elementen der Aristotelischen Logik* (1842; 3rd ed 1876); *Logische Untersuchungen* (1840; 3rd ed. 1870), and *Die logische Frage in Hegels System* (1843), important factors in the reaction against Hegel; *Historische Beiträge zur Philosophie* (1846–67), in three volumes, the first of which contains a history of the doctrine of the Categories; *Das Naturrecht auf dem Grunde der Ethik* (1860); *Lücken im*

Volkerrecht (1870), a treatise on the defects of international law, occasioned by the war of 1870

On Trendelenburg's life and work *see* H. Bonitz, *Zur Erinnerung an F.A.T* (1872), P. Kleinert, *Grabrede* (1872), E. Bratuschek, *Adolf Trendelenburg* (1873), C von Prantl, *Gedachtnissrede* (Munich, 1873), G. S Morris in the *New Englander* (1874), xxxiii

TRENT, the chief river in the midlands of England, the third in length in the country, exceeded only by the Thames and Severn. It rises in north Staffordshire, and discharges through the Humber into the North Sea, having a course of about 170 m The source is on Biddulph Moor The course is first southerly, and it skirts the Potteries, passing Stoke-on-Trent Passing Stone, the course becomes south-easterly, and the united waters of the Sow and the Penk are received on the right. Near Rugeley the direction becomes easterly, and near Alrewas the Trent receives the Tame (right), and turns to the north-east The river now passes Burton-on-Trent, in this part of its course forming the boundary between Staffordshire and Derbyshire The valley opens out as the stream, dividing into several channels at Burton and receiving on the left the Dove, enters Derbyshire. It then separates that county from Leicestershire and Nottinghamshire, receives in succession the Derwent (left), Soar (right) and Erewash (left), enters Nottinghamshire, and passes Nottingham, 81¼ m. from the mouth. The next important town is Newark, the Devon (right) joins here The valley becomes flat, though the river is rather deeply entrenched in some parts Forming the boundary between Nottingham and Lincolnshire, the Trent passes Gainsborough, receives the Idle (left) and, entering Lincolnshire and skirting the Isle of Axholme, joins the Yorkshire Ouse near Faxfleet The lower part of the valley resembles the Fens in character The highest tides are about 40 m up river, and the phenomenon of a bore is seen rising on spring tides to a height of 4 or 5 ft, 15 m above the mouth of the river

The Trent is navigable for 94¾ m from its junction with the Ouse, to a point a short distance above the junction of the Derwent It is also navigable for barges of 120 tons as far as Nottingham There are eight locks Below Gainsborough the navigation is open, and vessels drawing 9 ft can reach this point on spring tides. From the Derwent mouth the Trent and Mersey Canal follows the Trent valley upward, and gives connection with the inland navigation system of the midlands and west of England Short canals give access to Derby and the Erewash valley, the Leicester Navigation, following the Soar, connects with the Grand Junction canal; and the Grantham Canal carries a little traffic between that town and Nottingham The Fossdyke, connects the Trent with Lincoln and the Witham, and lower down the Sheffield and South Yorkshire canal joins the river from the west at Keadby There is also a canal, little used, to Chesterfield

TRENT (ITALY) *see* TRENTO

TRENT, COUNCIL OF. The Council of Trent (1545–1563) has a long antecedent history of great significance for the fortunes of the Catholic Church During the 15th and the earlier half of the 16th century, the conception of an "ecumenical council" remained an ideal of which the realization was expected to provide a solution for the serious ecclesiastical difficulties which were then prevalent The emperor Charles V urged on the papacy the necessity of convening a general assembly of the church The passive resistance of the Curia was so stubborn that the decisive step was postponed time and again But the goal was finally attained, and this result was the work of Charles, aided by three powerful cardinals

The bull *Laetare Hierusalem* (November 19. 1544) fixed the meeting of the council for March 15, 1545, in Trent, and assigned it three tasks: (1) the pacification of the religious dispute by doctrinal decisions. (2) the reform of ecclesiastical abuses, (3) the discussion of a crusade against the infidels

The opening of the council was deferred once again Towards the end of May 1545, twenty bishops were collected at Trent; but there was no sign of action, and the papal legates—Del Monte, Corvinus and Reginald Pole—delayed the inauguration, the emperor and the pope being at cross purposes as to procedure In the eyes of Paul III the council was simply the means by which he expected to secure a condemnation of the Protestant heresy, in hopes that he would then be in a position to impose the sentence of the Church upon them by force. For him the question of ecclesiastical reform possessed no interest whatever In contrast to this, Charles demanded that these very reforms should be given precedence, and the decisions on points of dogma postponed till he should have compelled the Protestants to send representatives to the council The pope, however, alarmed by the threat of a colloquy in Germany, at last ordered the synod to be opened (December 13, 1545).

The procedure adopted secured the predominance of the Roman chair from the first As the voting was not to be by nations, as at Constance, but by individuals, the last word remained with the Italians, who were in the majority.

The council began its work in the region of dogma by defining the doctrines of the Church with reference to the most important controversial points—a procedure which frustrated the emperor's hopes for a reconciliation with the Protestants. The doctrines dealt with, up to March 1547, were the Holy Scriptures and tradition (*sessio* iv), original sin (*sessio* v), justification (*sessio* vi.), and the sacraments in general, and baptism and confirmation in particular (*sessio* vii) In March the council was moved to Bologna on the pretext that an epidemic was raging in Trent (*sessio* viii.), though, at the imperial command, part of the bishops remained behind But on the 2nd of June the council of Bologna resolved (*sessio* x) to adjourn its labours At the Diet of Augsburg the emperor secured a *modus vivendi*, leavened by the Catholic spirit, between the adherents of either religion, and this provisory settlement—the so-called *Interim* of Augsburg—was promulgated as a law of the empire (June 3, 1548), and declared binding till the council should reassemble But the confusion of ecclesiastical affairs had grown worse confounded through the refusal of the pope to continue the council, when his death (November 10, 1549) changed the situation

Pope Julius III, the former legate Del Monte, caused the council to resume its labours on May 1, 1551 (*sessio* xi), under the presidency of Cardinal Crescentio The personnel was, for the most part, different, and the new members included the Jesuits, Laynez and Salmeron The French clergy had not a single delegate, while the Spanish bishops maintained an independent attitude under the aegis of the emperor, and Protestant deputies were on this occasion required to appear at Trent Their participation, however, was useless, for the discussion of doctrine on the basis of Holy Writ was from the Catholic standpoint impossible, and the revolt of the elector Maurice of Saxony (March 20, 1552) compelled the emperor to leave Innsbruck, and dissolved the conclave Its dogmatic labours were confined to doctrinal decrees on the Lord's Supper (*sessio* xiii), and on the sacraments of penance and extreme unction (*sessio* xiv) On April 28, 1552, the sittings were suspended

Ten years elapsed before the council reassembled for the third time in Trent During the intervening period, the religious problem in Germany had received such a solution as the times admitted by the peace of Augsburg (1555); and the equality there guaranteed between the Protestant estates and the Catholic estates had left the former nothing to hope from a council The incitement to continue the council came from another quarter. It was no longer anxiety with regard to Protestantism that exercised the pressure, but a growing conviction of the imperative need of more stringent reforms within the Catholic Church itself. In France and Spain—the very countries where the Protestant heresy had been most vigorously combated—a great mass of discontent had accumulated, and France already showed a strong inclination to attempt an independent settlement of her ecclesiastical difficulties in a national council. Pius IV. therefore announced (Nov 29, 1560) the convocation of the council; and on Jan. 18, 1562, it was actually reopened (*sessio* xvii.)

The Protestants indeed were also invited but the Evangelical princes, assembled in Naumburg, withheld their assent To secure freedom of action, France and the emperor Ferdinand required that it should rank as a new council; Pius IV, however, designated it a continuation of the earlier meetings. Ferdinand, in

addition to regulations for the amendment of the clergy and the monastic system, demanded above all the legalization of the marriage of the priesthood, while France and Spain laid stress on the recognition of the divine right of the episcopate, and its independence with regard to the pope. In consequence of these reformatory aspirations, the position of the pope and the council was for a while full of peril But the papal diplomacy, by concessions, threats, and by exploiting political and ecclesiastical dissensions, broke the force of the attack. In the third period of the council, which, as a result of these feuds, witnessed no session from September 1562 to July 1563, doctrinal resolutions were also passed concerning the Lord's Supper *sub utraque specie* (*sessio* xxi), the sacrifice of the Mass (*sessio* xxii.), the sacrament of ordination (*sessio* xxiii.), the sacrament of marriage (*sessio* xxiv.), and Purgatory, the worship of saints, relics and images. On Dec. 4, 1563, the synod closed.

The dogmatic decisions of the Council of Trent make no attempt at embracing the whole doctrinal system of the Roman Catholic Church, but present a selection of the most vital doctrines, partly chosen as a counterblast to Protestantism, and formulated throughout with a view to that creed and its objections

The reformatory enactments touch on numerous phases of ecclesiastical life—administration, discipline, appointment to spiritual offices, the marriage law (*decretum de reformatione matrimonii "Tametsi," sessio* xxiv), the duties of the clergy, and so forth. The resolutions include many that marked an advance, but the opportunity for a comprehensive and thorough reformation of the life of the Church—the necessity of which was recognized in the Catholic Church itself—was not embraced No alteration of the abuses which obtained in the Curia was effected, and no annulment of the customs, so lucrative to that body and deleterious to others, was attempted

The Council of Trent in fact enjoyed only a certain appearance of independence For the freedom of speech which had been accorded was exercised under the supervision of papal legates, who maintained a decisive influence over the proceedings and could count on a certain majority in consequence of the overwhelming number of Italians That the synod figured as the responsible author of its own decrees (*sancta oecumenica et generalis tridentina synodus in spiritu sancto legitime congregata*) proves very little, since the following clause reads *praesidentibus apostolicae sedis legatis;* while the legates and the pope expressly refused to sanction an application of the words of the Council of Constance—*universalem ecclesiam repraesentans.*

The whole course of the council was determined by the presupposition that it had no autonomous standing, and that its labours were simply transacted under the commission and guidance of the pope This was not merely a claim put forward by the Roman see at the time, it was acknowledged by the attitude of the synod throughout The legates confined the right of discussion to the subjects propounded by the pope, and their position was that he was in no way bound by the vote of the majority. In difficult cases the synod itself left the decision to him, as in the question of Clandestine Marriages and the Administration of the Lord's Supper *sub utraque specie.* Further, at the close of the sessions a resolution was adopted, by the terms of which all the enactments of the council *de morum reformatione atque ecclesiastica disciplina* were subject to the limitation that the papal authority should not be prejudiced thereby (*sessio* xxv *cap.* 21). Every doubt as to the papal supremacy is removed when we consider that the Tridentine Fathers sought for all their enactments and decisions the ratification (*confirmatio*) of the pope, which was conferred by Pius IV. in the bull *Benedictus Deus* (January 26, 1564); and in its last meeting (*sessio* xxv) the synod transferred to the pope a number of tasks for which their own time had proved inadequate. These comprised the compilation of a catalogue of forbidden books, a catechism, a short conspectus of the articles of faith and an edition of the missal and the breviary. Thus the council presented the Holy See with a further opportunity of extending its influence and diffusing its views. The ten rules *de libris prohibitis* were published in March 1564; the *Professio fidei tridentinae* in November 1564; and the *Catechismus a decreto concilii tridentini ad parochos*, early in 1568

The oecumenical character of the council was never seriously questioned. On the motion of the legates, the resolutions were submitted to the ambassadors of the secular powers for signature, the French and Spanish envoys alone withholding their assent The recognition of the council's enactments was, none the less, beset with difficulties So far as the doctrinal decisions were concerned no obstacles existed, but the reformatory edicts—adhesion to which was equally required by the synod—stood on a different footing In their character of resolutions claiming to rank as ecclesiastical law they came into conflict with outside interests, and their acceptance by no means implied that the rights of the sovereign, or the needs and circumstances of the respective countries were treated with sufficient consideration The consequence was that there arose an active and, in some cases, a tenacious opposition to an indiscriminate acquiescence in all the Tridentine decrees, especially in France, where only those regulations were recognized which came into collision neither with the rights of the king nor with the liberties of the Gallican Church. In Spain Philip II. allowed, indeed, the publication of the *Tridentinum*, but always with the reservation that the privileges of the king, his vassals and his subjects, should not thereby be infringed

In his official confirmation Pius IV had already strictly prohibited any commentary on the enactments of the council unless undertaken with his approval, and had claimed for himself the sole right of interpretation. In order to supervise the practical working of these enactments, Pius created (1564) a special department of the Curia, the *Congregatio cardinalium concilii tridentini interpretum;* and to this body Sixtus V entrusted the further task of determining the sense of the conciliar decisions in all dubious cases. The *resolutiones* of the congregation—on disputed points—and their *declarationes*—on legal questions—exercised a powerful influence on later development of ecclesiastical law

The Council of Trent attained a quite extraordinary significance for the Roman Catholic Church, and its pre-eminence was unassailed till the *Vaticanum* subordinated all the labours of the Church in the past—whether in the region of doctrine or in that of law—to an infallible pope On the theological side it fixed the results of mediaeval scholasticism and drew from it all that could be of service to the Church. Further, by pronouncing on a series of doctrinal points till then undecided it elaborated the Catholic creed; and, finally, the bold front which it offered to Protestantism in its presentation of the orthodox faith gave to its members the practical lead they so much needed in their resistance to the Evangelical assault. It showed that Church as a living institution, capable of work and achievement, it strengthened the confidence both of her members and herself, and it was a powerful factor in heightening her efficiency as a competitor with Protestantism and in restoring and reinforcing her imperilled unity Indeed, its sphere of influence was still more extensive, for its labours in the field of dogma and ecclesiastical law conditioned the future evolution of the Roman Catholic Church

Bibliography —Supreme among the sources for the history of the council stands the splendidly planned work *Concilium tridentinum; diariorum, actorum, epistularum, tractatuum nova collectio*, ed Societas Goerresiana (in successive volumes, 1901 ff) The following deserve special mention: P Sarpi, *Istoria del concilio tridentino* (London, 1619); Cardinal Sforza Pallavicini, *Istoria del concilio di Trento* (Rome, 1656–57, a counterblast to the preceding); Brischar, *Zur Beurteilung der Kontroversen zwischen Sarpi und Pallavicini* (1844); J. TRENTE ET QUARANTE (called also *Rouge et Noir*), a game of French origin played with cards and a special table. It is one of the two games played in the gambling rooms at Monte Carlo, roulette being the other. The diagram illustrates one half of the table, the other half precisely corresponding to it. Two croupiers sit on each side, one of them being the dealer; behind the two on the side opposite to the dealer a supervisor of the game has his seat. Six packs of fifty-two cards each are used; these are well shuffled, and the croupier asks any of the players to cut, handing him a blank card with which to divide the mixed packs There are only four chances at trente et quarante. *rouge* or *noir*, known as the *grand tableau*, *couleur* or *inverse*, known as the *petit tableau*. At Monte Carlo the stakes are placed on the divisions indicated on the table, the maximum being 12,000 francs and the minimum 20 francs which must be staked in counters. The dealer, who has placed all the cards before him, separates a few with the blank card, takes them in his left hand and invites the players to stake with the formula, "Messieurs, faites votre jeu!" After a pause he exclaims "Le jeu est fait, rien ne va plus!" after which no stake can be made. He then deals the cards in a row until the aggregate number of pips is something more than 30, upon which he deals a second row, and that which comes nearest to 30 wins, the top row being always distinguished as *noir*, and the lower as *rouge* In announcing the result the word *trente* is always omitted, the dealer merely announcing *un*, *trois*, *quatre*, as the case may be, though when 40 is turned up it is described as *quarante*. The words *noir* and *inverse* are also never used, the announcement being *rouge gagne* or *rouge perd*, *couleur gagne* or *couleur perd* Gain or loss over *couleur* and *inverse* depends upon the colour of the first card dealt. If this should be also the colour of the winning row, the player wins. Assuming, for example, that the first card dealt is red, and that the lower row of the cards dealt is nearest to 30, the dealer will announce "Rouge gagne et le couleur." If the first card dealt is red, but the black or top row of cards is nearest to 30, the dealer announces "Rouge perd et le couleur." It frequently happens that both rows of cards when added together give the same number. Should they both, for instance, add up to 33, the dealer will announce "Trois après," and the deal goes for nothing except in the event of their adding up to 31. *Un après* (*i e.*, 31) is known as a *refait;* the stakes are put in prison to be left for the decision of the next deal, or if the player prefers it he can withdraw half his stake, leaving the other half for the bank. Assurance against a *refait* can be made by paying 1% on the value of the stake with a minimum of five francs. When thus insured against a *refait* the player is at liberty to withdraw his whole stake. It has been calculated that on an average a *refait* occurs once in 38 coups After each deal the cards are pushed into a metal bowl let into the table in front of the dealer. When he has not enough left to complete the two rows, he remarks "Les cartes passent"; they are taken from the bowl, reshuffled, and another deal begins.

DIAGRAM SHOWING HALF OF TRENTE ET QUARANTE TABLE

TRENTINO, a mountainous area of North Italy, extending E. and W. of the middle course of the Adige. Before the World War it was part of the Austrian province of Tirol. The Trentino frontier, which had been delimited after the war of 1866, was strategically most unfavourable to Italy, as it left the mountain ranges wholly in Austrian hands and formed a wedge whence a dozen military roads branched outwards threatening the richest and most fertile parts of Italy It also left 400,000 Italians under Austrian rule. During the war the Trentino was the scene of heavy fighting, which extended from the Stelvio pass to the Ampezzo valley and spread over into the Asiago plateau within the borders of Italy. Early in the war the Italian troops occupied a number of positions beyond the frontier, especially east of the Adige, whence their line extended from north of Mori, along the Terragnolo valley, Costa d'Agra, across the Astico, Cima Mandriolo, across the river Brenta in the Val Sugana to the Cima d'Asta; farther east all the Ampezzo valley was occupied to the Tofana and Cristallo groups. There were many engagements in the autumn and winter of 1915, especially north of the Cadore and at the head of the Cordevole valley round the Col di Lana, the attacks on which caused serious losses to the Italians, until in April 1916 the summit was blown up by an Italian mine and the hill remained in Italian hands. The fighting on the Stelvio, the Adamello, the Ampezzo group and the peaks round San Martino di Castrozza was at a very high altitude, and the troops had to perform what even in ordinary times would be regarded as notable mountaineering exploits amid ice, snow and extremely difficult rocky terrain, exposed to intense cold, severe storms and heavy enemy fire, the Austrians usually holding the most favourable positions. Roads had to be built up the most precipitous mountains and heavy guns dragged up to a height of 2,000 to 3,000 feet The Italians managed to capture many of these positions, although at the cost of heavy losses; but in May 1916 the Austrians, after an intense artillery preparation with masses of heavy guns, launched a formidable attack on the Terragnolo–Val Sugana–Folgaria–Asiago area and drove the Italians back for a considerable distance. The object was to debouch into the Vicenza plain and cut the communications with the Isonzo army. There was desperate fighting along the whole line, but the key positions of Coni Zugna, Passo Buole and the Pasubio to the west and the peaks on the outer edge of the Asiago plateau on the east held firm. By June 16 the momentum of the Austrians had exhausted itself, and an Italian counter-attack recovered most of the lost ground After the Austrian break-through at Caporetto in Oct. 1917, an attempt was made to effect a breach also in the Asiago plateau. The Ampezzo and Cadore areas had to be evacuated by the Italians, and in the heavy fighting through Nov and Dec. some of the positions on the plateau were again lost, but the outer edge was held, and the Austrians failed to descend into the plain In the battle of June 1918, when the west sector of the Asiago area was held by British troops, another attack was delivered there, and although the Austrians at first broke through at several points they were driven back to their original line. When the final battle of the war began (Oct 23, 1918) the Italians, together with British and French forces, carried out a demonstrative action to prevent the enemy from shifting reserves to the Grappa and Piave areas where the main attacks were being delivered. It was from the Asiago plateau that the victorious troops on Nov. 1 poured into the Val Sugana, while the I. Army advanced up the Adige valley and the two forces converged on Trento, which was reached on Nov. 3.

TRENTO (Lat *Tridentum;* Ger. *Trent* or *Trient*), the capital of a province in the district of Venezia Tridentina, Italy. Pop. (1921), 31,881, town; 35,130, commune. It stands on the left bank of the Adige where this river is joined by the Fersina, and is a station on the Brenner railway, 35 m S of Bolzano and 56½ m. N of Verona, while a railway runs along the Fersina valley and the Val Sugana to Bassano (60 m.). There is also an electric railway to Malè (45 m. N.). It has a very picturesque appearance, especially when approached from the north, with its embattled walls and towers filling the whole breadth of the valley. A conspicuous feature in the view is the isolated rock Doss Trento (the site of the Roman *Verruca*), that rises on the right bank of the Adige to a height of 308 ft. above the city. The cathedral (dedicated to San Vigilio, the first bishop) was altered at various times between the 11th and 15th centuries, and was restored in 1882–89. Outside is the fine fountain of Neptune (1767–69). The Renaissance church of Santa Maria Maggiore, built in 1520–39, was the scene of the sessions of the famous Oecumenical Council (*see* p. 454) which lasted, with several breaks, from 1545 to 1563, during the episcopate of Cristoforo Madruzzo. To the east of the city rises the Castello del Buon Consiglio, for centuries the residence of the prince-bishops, which is decorated with interesting frescoes, and contains the museum of antiquities and fine arts

for the district. Opposite the railway station a statue of Dante by Zocchi was erected in 1896.

Tridentum, the capital of the Tridentini, was a station on the great road from Verona to Veldidena (Innsbruck) over the Brenner. It was later ruled by the Ostrogoths (5th century) and the Lombards (6th century) after the conquest of whom by the Franks (774) Trento became part of the kingdom of Italy. But in 1027 the emperor Conrad II bestowed all temporal rights in the region on the bishop (the see dates from the 4th century) and transferred it to Germany, an event which fixed all its later history. The Venetian attacks were finally repulsed in 1487, and the bishop retained his temporal powers till 1803 when they passed to Austria In 1814 the Trentino was formally annexed to the Austrian province of Tirol. Trento became an Italian city in 1919, when the Trentino passed from Austrian to Italian hands.

TRENTON, a city of Missouri, U S A., 100 m. N E of Kansas City, on the east fork of the Grand river, the county seat of Grundy county. It is on Federal highway 65, and is served by the Quincy, Omaha and Kansas City and the Rock Island railways Pop. (1920) 6,951 (96% native white); estimated locally at 8,000 in 1928. The Rock Island railway has repair shops here Trenton was platted as the county seat in 1841, incorporated as a town in 1857, and chartered as a city in 1893.

TRENTON, the capital city of New Jersey, U S A., and the county seat of Mercer county, on the Lincoln highway and the east bank of the Delaware river, 30 m N E of Philadelphia and 55 m S W of New York city It has a county airport, and is served by the Pennsylvania and the Reading railways, 4 interurban electric lines, numerous motor-bus and truck lines and small steamers and barges on the Delaware river and through the Delaware and Raritan canal to the Raritan river at New Brunswick Pop (1920) 119,289 (25% foreign-born white); 1928 estimate 139,000, with 35,000 more in contiguous suburbs.

Trenton is at the head of navigation on the Delaware, which falls 8 ft. at this point Three miles of the water front is occupied by Riverside park, and there are municipal docks, wharves and warehouses, with which a public roof-garden is combined. The city has an area of 8 5 sq m , of which 266 ac are in public parks; an assessed valuation for 1928 of $248,089,324; and commission form of government, adopted in 1911 It is the seat of a State normal school (1855), the State library, the State school for the deaf, the State home for girls, a State hospital for the insane (1848), the State prison (1836) and the State arsenal, occupying the old prison. The State House stands on high ground not far from the river In Mahlon Stacy park, adjoining the Capitol grounds, are the "Hessian" barracks, erected by the Colony in 1758 to mitigate the evils of billeting, and occupied by British troops during the Seven Years' War, and at different times during the Revolution by British, Hessian and American troops. Washington's crossing of the Delaware on Christmas night, 1776, took place 8 m above Trenton, and in the centre of the city stands a granite column 150 ft high, marking the spot where he planted his guns in the Battle of Trenton on the following day. Among the interesting old houses are "Woodland" (formerly called "Bloomsbury Court"), built early in the 18th century by William Trent, "The Hermitage," and "Bow Hill," a quaint colonial mansion in the suburbs, which for some time before 1822 was the home of Joseph Bonaparte Trenton is the see of Roman Catholic and Protestant Episcopal bishops There are 100 churches in the city, 33 public and 17 parochial schools, hospitals with about 900 beds and a number of homes and other charitable institutions under religious auspices. The Trenton Municipal Colony, on the outskirts of the city, is an assemblage of the city's institutions for the care of the sick and the aged, in connection with a farm of 25 acres. There are two daily papers: the *State Gazette*, established in 1792, and the *Times* (1882).

Trenton is an important industrial city, with 303 manufacturing establishments in 1925, producing goods valued at $126,516,024, of which $16,084,831 represented pottery (14% of the total produced in the United States) and $2,768,250 other clay products. Bank debits in 1927 aggregated $905,187,000.

In 1680 Mahlon Stacy, a Quaker of Burlington, erected a mill on the Delaware here, at the mouth of the Assanpink creek, and by 1685 a small settlement had grown up around it. In 1714 Stacy sold his plantation at "The Falls" to William Trent, later chief justice of New Jersey, after which the village came to be known as Trent-town, or Trenton. In 1745 Trenton was incorporated as a borough by a royal charter, but in 1750 the citizens voluntarily surrendered this privilege, deeming it "very prejudicial to the interest and trade" of the community. In 1783 Trenton was proposed by the New Jersey delegates in Congress for the seat of the Federal Government, and in Nov. 1784, while it was under consideration, Congress met here for a brief period. It became the capital of the State in 1790 and was chartered as a city in 1792 The modern pottery industry dates from 1852. In 1860 the population was 17,228; in 1880, 29,910; in 1900, 73,307; and in 1910, 96,815. There have been no annexations of territory since 1900.

TRENTON AND PRINCETON, BATTLES OF (1776-1777) These battles in the War of American Independence are noted as the first successes won by Washington in the open field. Following close upon a series of defeats, their effect upon his troops and the population at large was marked After the capture of Ft Washington on Manhattan island, on Nov. 16, 1776, the British general, Sir William Howe, forced the Americans to retreat through New Jersey and across the Delaware into Pennsylvania. Howe then went into winter quarters, leaving the Hessian general, Rahl, at Trenton on the river with a brigade of 1,200 men Although Washington's army was discouraged by the year's disasters, it could still be trusted for a promising exploit, and by reinforcements had been brought up to 6,000 effectives. Ascertaining that the Hessians at Trenton were practically unsupported, the American general determined to attempt their capture. He planned to recross the Delaware with three columns, but only his own got across The passage was made on the night of Dec 25, 1776, through floating ice, to a point 9m above the enemy, whom he expected to reach at dawn of the following day, the 26th. Dividing his force of 2,500 men into two divisions under Generals Sullivan and Greene, he approached the town by two roads, surprised the Hessian outposts, and then rushed upon the main body before it could form effectively. The charge of the American troops and the fire of their artillery and musketry completely disconcerted the enemy All avenues of retreat being closed and their general mortally wounded, the latter to the number of 950 quickly surrendered.

Elated by this success and eager to harass the enemy's advanced posts at other points, Washington again crossed the Delaware on Dec 30, and occupied Trenton Hearing of this move Lord Cornwallis at Princeton, 10m north of Trenton, marched down with about 7,000 troops upon the Americans on Jan. 2, 1777, and drove them across the Assanpink, a stream running east of the town The Americans, who encamped on its banks that night, were placed in a precarious position, as the Delaware, with no boats at their disposal at that point, prevented their recrossing into Pennsylvania, and all other roads led towards the British lines to the northward Washington accordingly undertook a bold manoeuvre Fearing an attack by Cornwallis on the next morning, he held a council of war, which confirmed his plan of quietly breaking camp that night and taking a by-road to Princeton, then cutting through any resistance that might be offered there and pushing on to the hills of northern New Jersey, thus placing his army on the flank of the British posts. His tactics succeeded At Princeton (*q v*) he came upon three British regiments, which for a time held him at bay. The 17th foot especially, under Colonel Mawhood, twice routed the American advanced troops, inflicting severe loss, but were eventually driven back toward Trenton. The other regiments retreated north toward New Brunswick, and Washington continued his march to Morristown, New Jersey Here he was on the flank of the British communications with New York, and hence Cornwallis retired to New Brunswick Washington, besides his success in breaking through Howe's lines, had placed himself in an advantageous position for recruiting his army and maintaining a strong defensive in the next campaign These two affairs of Trenton and

Princeton put new life into the American cause, and established Washington in the confidence of his troops and the country

See W. S. Stryker, *The Battles of Trenton and Princeton* (Boston, 1898); and Varnum L. Collins, ed., "A Contemporary Account of the Battles of Trenton and Princeton," *Princeton Hist. Assoc.*, Extra pub. No. 1 (Princeton, N.J., 1906).

TREPOV, DIMITRI FEODOROVICH (1855–1906), Russian general, chief of the imperial police, born at St. Petersburg (Leningrad), was city prefect of Moscow. In the disturbances of 1905 he was placed in command of St. Petersburg, when he immediately took steps to expel all those who had taken part in the procession led by Father Gapon to the Winter Palace The result was an epidemic of strikes throughout the empire. In the railway strike (Oct 20) Trepov gave the famous order to the troops "not to spare their cartridges" He was now made commandant of the imperial police, and used his great power to undermine the authority of Count Witte with the tsar. He then became assistant-minister of the interior An unsuccessful attempt to assassinate him was made on March 30, 1905 He died on Sept. 15, 1906.

TRESCOT, WILLIAM HENRY (1822–1898), American diplomatist, was born in Charleston, S C., on Nov 10, 1822 He graduated at Charleston college in 1840, studied law at Harvard, and was admitted to the bar in 1843 In June, 1860 he was appointed assistant secretary of State, and he was acting secretary of State in June-October, during Gen Lewis Cass's absence from Washington His position was important, because of his intimacy with President Buchanan and his close relations with the secession leaders in South Carolina He opposed the re-enforcement of Ft Sumter and used his influence to prevent any attack on the fort by South Carolina before the meeting of the State's convention called to consider the question of secession. He returned to Charleston in Feb. 1861; served as colonel on the staff of Gen. Roswell S Ripley during the Civil War, and later returned to Washington. He was counsel for the United States before the Halifax Fishery commission in 1877; was minister to Chile in 1881–82 and in 1882 with Gen. U S Grant negotiated a commercial treaty with Mexico. He died at Pendleton, S C, on May 4, 1898

His writings include *The Diplomacy of the Revolution* (1852), *An American View of the Eastern Question* (1854) and *The Diplomatic History of the Administrations of Washington and Adams* (1857).

TRESPASS, in law, any transgression of the law less than treason, felony or misprision of either. The term includes a great variety of wrongs committed to land, goods or person Up to 1694 the trespasser was regarded, nominally at any rate, as a criminal, and was liable to a fine for the breach of the peace, commuted for a small sum of money, for which 5 Will and Mar c. 12 (1693) substituted a fee of 6s 8d recoverable as costs against the defendant Trespass is not now criminal except by special statutory enactment, *e g*, the old statutes against forcible entry, the game acts, and the private acts of many railway companies. When, however, trespass is carried sufficiently far it may become criminal, and be prosecuted as assault if to the person, as nuisance if to the land At one time an important distinction was drawn between trespass general and trespass special or trespass on the case, for which *see* TORT.

In its more restricted sense trespass is generally used for entry on land without lawful authority by either a man, his servants or his cattle. To maintain an action for such trespass the plaintiff must have possession of the premises The most minute invasion of private right is trespass In addition to damages for trespass, an injunction may be granted by the court

Trespass may be justified by exercise of a legal right, as to serve the process of the law, or by invitation or licence of the owner, or may be excused by accident or inevitable necessity, as deviation from a highway out of repair.

In Scots law trespass is used only for torts to land. By the Trespass (Scotland) Act 1865 trespassers are liable on summary conviction to fine and imprisonment for encamping, lighting fires, etc., on land without the consent and permission of the owner.

In the United States, common law doctrines as to trespass hold in most of the States It means, more particularly, an injury to the person, property or rights of another, as the immediate result of a wrongful act committed with actual or implied force. The statutes have provided for criminal trespass in many States, but not to the extent as existed prior to 1694 in England. Trespass on the realty of another often is a criminal offence, through statutory enactment in the States.

TRES TABERNAE (Three Taverns), an ancient village of Latium, Italy, a post station on the Via Appia. It is probable that it stood at Cisterna, where a branch road running from Antium joins the Via Appia. Tres Tabernae is best known as the point to which St. Paul's friends came to meet him on his journey to Rome (Acts xxviii. 15). It became an episcopal see, but this was united with that of Velletri in 592

TRESVIRI or **TRIUMVIRI,** in Rome, a board of three, either ordinary officials or extraordinary commissioners.

1. *Tresviri capitales,* whose duty it was to assist the higher magistrates in their judicial functions, especially criminal, were first appointed about 289 B C. They possessed no criminal jurisdiction or *ius prensionis* (right of arrest) in their own right. They kept watch over prisoners and carried out the death sentence; took accused or suspected persons into custody, and exercised general control over the city police They went the rounds by night to maintain order, and had to be present at outbreaks of fire They assisted the aediles in burning forbidden books. They had to collect the *sacramenta* (deposit forfeited by the losing party in a suit) and examined the plea of exemption put forward by those who refused to act as jurymen In imperial times most of their functions passed into the hands of the *praefectus vigilum.*

2 *Tresviri epulones,* a priestly body, assisted at public banquets They were first created in 196 B C to superintend the *epulum Iovis* (banquet of Jupiter) on the Capitol, but their services were also requisitioned on the occasion of triumphs, imperial birthdays, the dedication of temples, games given by private individuals, and so forth, when entertainments were provided for the people.

3. *Tresviri monetales* were superintendents of the mint, up to the Social War occasional, afterwards permanent, officials. As they acted for the senate they only coined copper money under the empire, the gold and silver coinage being under the exclusive control of the emperor.

4 *Tresviri reipublicae constituendae* was the title bestowed upon Octavianus, Lepidus and Antony for five years by the lex Titia, 43 B C The coalition of Julius Caesar, Pompey and Crassus has also been called a "triumvirate," but they never had the title *tresviri,* and were not a formally appointed commission

TREVELYAN, GEORGE MACAULAY (C B E 1920), English historian (1876–), third son of Sir George Otto Trevelyan (*q v*), was born on Feb 16, 1876, and educated at Harrow and at Trinity college, Cambridge During the World War he served as Commandant of the 1st British Ambulance unit for Italy (1915–18). In 1927 he became regius professor of modern history at Cambridge.

His numerous publications include: *England under the Stuarts* (1907); *Garibaldi and the Making of Italy* (1911), *The Life of John Bright* (1913), *Lord Grey of the Reform Bill* (1920); *British History of the Nineteenth Century, 1782–1901* (1922); *Manin and the Venetian Revolution of 1848* (1923) and *History of England* (1926).

TREVELYAN, SIR GEORGE OTTO, O.M. 1911 (1838–1928), English historian, was born on July 20, 1838, at Rothley Temple, Leicestershire, the son of Sir C E. Trevelyan and his wife Hannah More Macaulay. He had a brilliant career at Harrow, which he entered in 1851, and at Trinity College, Cambridge. In 1862 he went to India as his father's private secretary, and while there wrote two humorous books, *The Dawk Bungalow,* and *The Competition Wallah,* and in 1865 his first serious work, *Cawnpore.* In 1864 he was again in London, and the following year was returned as Liberal M P. for Tynemouth. From 1868 to 1887 he represented the Hawick Burghs, and from

1887 until his retirement in 1897, the Bridgeton division of Glasgow. In 1868 he had become a civil lord of the Admiralty, but resigned two years later. He then completed his *Life* of his uncle Lord Macaulay, which was immediately recognised as a masterpiece of biography. He was for two years (1880–82) secretary to the Admiralty, and then became for a year chief secretary for Ireland, after the murder of Lord Frederick Cavendish The strain of this position told severely on his health, and he returned in 1884, and was given the office of the duchy of Lancaster, with a seat in the cabinet He was credited with a large share in the authorship of the measure extending household suffrage to the counties (1885) He was secretary for Scotland in the first Home Rule parliament, but resigned with Chamberlain two months later. With Chamberlain he joined the Round Table Conference on the Irish question at Harcourt's house. Finding, however, that Liberal Unionism could not stand alone, he took office under Gladstone in 1892 as secretary for Scotland, a post which he held also in Lord Rosebery's government His many honours were crowned in 1911 with the Order of Merit

His *Life and Letters of Lord Macaulay* (1876) still holds its place as a biography of the first importance, and a new edition was issued in 1923. His next work was *The Early History of Charles James Fox* (1880). The second volume which he intended to write, was put aside in favour of his history of *The American Revolution* This history led to a long and interesting correspondence with Roosevelt, to whom he sent a copy in 1904, some of Roosevelt's letters being published later in *Scribner's Magazine*.

He married in September, 1869, Caroline, daughter of R. N. Philips He died on Aug 16, 1928, and was succeeded in the baronetcy by his eldest son, Charles Philips Trevelyan, M P (b 1870) who was minister for education in Ramsay MacDonald's two administrations, in 1924 and 1928 His second son, Robert Calverley Trevelyan, is the author of admirable translations from the Greek drama, and of original verse His third son was George Macaulay Trevelyan (*q v*)

TREVES, SIR FREDERICK (1853–1923), British surgeon, was born at Dorchester on Feb 15, 1853, and was educated at Merchant Taylor's school, London, and the London hospital, where he became surgical registrar In 1881 he was appointed as professor of pathology and in 1885 as professor of anatomy at the Royal College of Surgeons, subsequently going into private practice He served as consulting surgeon during the South African War in 1900, and was made surgeon extraordinary to Queen Victoria in that year and surgeon to King Edward VII in 1901 He operated on King Edward VII when he fell ill in June 1902 He was created K C V O in 1901 and a baronet in 1902, and later serjeant-surgeon to King George and surgeon in ordinary to Queen Alexandra During the World War he assisted in the founding of the British Red Cross

His publications include several surgical and medical books, of which *Surgical Applied Anatomy* (1883) is well known, as well as a number of more popular books such as *The Tales of a Field Hospital* (1900), *The Riviera of the Corniche Road* (1921), *The Lake of Geneva* (1922), and *The Elephant Man and Other Reminiscences* (1923).

TREVET (or TRIVET), **NICHOLAS** (*c* 1258–*c* 1328), English chronicler, was the son of Sir Thomas Trevet (d 1283), a judge, and became a Dominican friar. After studying at Oxford and in Paris, he spent most of his subsequent years in writing and teaching, and died about 1328 His chief work is his *Annales sex regum Angliae*, a chronicle of English history covering the period between 1135 and 1307, this is valuable for the later part of the reign of Henry III. and especially for that of Edward I.

The *Annales* were published in Paris in 1668, in Oxford in 1719, and were edited by Thomas Hog for the English Historical Society in 1845 Manuscripts are at Oxford and in the British Museum.

TREVI (anc. *Trebiae*), a town of the province of Perugia, Italy, 30 m S E. of Perugia and 5 m S of Foligno by rail. Pop. (1921), 4,566 (town); 6,009 (commune). The town stands on a steep hill 1,355 ft above sea-level. Several of its churches are architecturally interesting, especially the Madonna delle Lacrime (1487) outside the town, and most of them (and also the municipal picture gallery) contain paintings by artists of the Umbrian school—notably Lo Spagna, a pupil of Perugino. The cathedral (S. Emiliano) has a group of three altars decorated with fine sculptures by Rocco da Vicenza (1521).

TREVISO (anc TARVISIUM), a town and episcopal see of Venetia, Italy, capital of the province of Treviso, 49 ft. above sea-level. Pop. in 1921, 35,366 (town); 49,737 (commune) It is situated on the plain between the Gulf of Venice and the Alps, 18 m by rail north of Venice, at the confluence of the Sile with the Botteniga The former flows partly round its walls, the latter through the town, and it has canal communication with the lagoons It has narrow irregular colonnaded streets and old frescoed houses The cathedral of San Pietro, dating from 1141 and restored and enlarged in the 15th century by Pietro Lombardo, with a classical façade of 1836, has seven domes It contains a fine "Annunciation" by Titian (1519), an important "Adoration of the Shepherds" by Paris Bordone (born at Treviso in 1500), and frescoes by Pordenone. There are also sculptures by Lorenzo and Battista Bregno and others The baptistery is Romanesque. The Gothic church of San Nicolò (1310–52) contains important works of art, including a large altarpiece by Fra Marco Pensabene and others, in the church and adjoining chapter-house are frescoes by Tommaso da Modena (1352), some frescoes by whom (life of S Ursula) are also in the Museo Civico The churches of S Leonardo, S Andrea, S Maria Maggiore, and S Maria Maddalena also contain art treasures The Piazza dei Signori contains picturesque brick battlemented palaces—the Palazzo dei Trecento (*c* 1207) and the Palazzo Pretorio (1218–68) The loggia dei Cavalieri (1195) is also fine.

The ancient Tarvisium lay off the main roads, and is hardly mentioned by ancient writers In the 6th century it appears as an important place and was the seat of a Lombard duke. Charlemagne made it the capital of a marquisate. It joined the Lombard league, and was independent after the peace of Constance (1183) until, in 1339, it came under the Venetian sway From 1318 it was for a short time the seat of a university Its walls and ramparts were renewed under the direction of Fra Giocondo (1509), two of the gates, the Porta Mazzini and Porta Cavour, dating from 1517–18 Treviso was taken in 1797 by the French under Mortier (duke of Treviso) In March 1848 the Austrian garrison was driven from the town by the revolutionary party, but in the following June the town was bombarded and compelled to capitulate.

See A Marchesan, *Treviso medioevale* (Treviso, 1923).

TREVITHICK, RICHARD (1771–1833), English engineer and inventor, was born on April 13 in the parish of Illogan, Cornwall, and was the only son of Richard Trevithick (1735–97), manager of the Dolcoath and other important Cornish mines His earliest invention of importance was his improved plunger pole pump (1797) for deep mining, and in 1798 he applied the principle of the plunger pole pump to the construction of a water-pressure engine, which he subsequently improved in various ways Two years later he built a high-pressure non-condensing steam-engine, which became a rival of the low-pressure steam-vacuum engine of Watt He was a precursor of George Stephenson in the construction of locomotive engines On Christmas Eve 1801 his common road locomotive carried the first load of passengers ever conveyed by steam, and on March 24, 1802 he and Andrew Vivian applied for a patent for steam-engines in propelling carriages In 1803 another steam vehicle made by him was run in the streets of London, from Leather Lane along Oxford Street to Paddington, the return journey being made by Islington He next built a steam locomotive for tramways, and in Feb. 1804 at Pen-y-darran in Wales he worked a tramroad locomotive which was able to haul 20 tons of iron; a similar engine was supplied to the Wylam colliery (Newcastle) in the following year. In 1808 he constructed a circular railway in London near Euston Square, on which the public were carried at the rate of 12 or 15 miles an hour round curves of 50 or 100 ft. radius. Trevithick applied his high-pressure engine with great success to rock boring and breaking, as well as to dredging. In 1806 he contracted with the board of Trinity House, London, to lift ballast from the bottom of the Thames, at the rate of 500,000 tons a year, for a payment of 6d a ton. Trevithick

was the first to recognize the importance of iron in the construction of large ships, and in various ways his ideas also influenced the construction of steamboats He was a pioneer in the application of steam to agriculture A high-pressure steam threshing engine was erected by him in 1812 at Trewithen, while in the same year, in a letter to the Board of Agriculture, he stated his belief that every process in agriculture might be performed by steam, and that such a use of the steam-engine would "double the population of the kingdom and make our markets the cheapest in the world." In 1814 he entered on an agreement for the construction of engines for mines in Peru, and to superintend their working removed to Peru in 1816. Thence he went in 1822 to Costa Rica He returned to England in 1827, and in 1828 petitioned parliament for a reward for his inventions, but without success. He died, penniless, at Dartford on April 22, 1833.

A *Life of Richard Trevithick, with an account of his Inventions* was published in 1872 by his third son, Francis Trevithick (1812–77).

TRIAL: *see* PRACTICE AND PROCEDURE

TRIAL BY BATTLE: *see* DUEL and WAGER.

TRIAL OF ANIMALS, an ancient legal custom which persisted in Europe until recent times and which is continued by various savage or barbaric peoples There is evidence that it grew out of the popular belief that animals are intelligent and consequently morally responsible for their acts However, the old doctrine of deodand (*q v*), which penalized inanimate objects that had taken human life, may be germane to the concept of the responsibility of animals, in which case both must be traced to the idea underlying animism. that not only human beings, but all other entities, are endowed with volition and consciousness An early example of legal procedure against animals is furnished by Exodus xxi, 28: "And if an ox gore a man or a woman to death, the ox shall be surely stoned " Plato, in *The Laws,* prescribed that "If a beast of burden or any other animal shall kill anyone, except while the animal is competing in the public games, the relatives of the deceased shall prosecute it for murder."

In Western Europe procedure against animals was settled, both in the ecclesiastical and civil courts; in all cases they were provided with counsel, were duly summoned to appear, exceptions taken in their favour were considered, and their sentences sometimes commuted on the grounds of relative youth, exiguity of body, or a reputation for respectability. a she-ass condemned to death in France in 1750 was pardoned because of good character.

TRIANGLE. A triangle, or more precisely a plane triangle, is the geometrical figure composed of three points called the *vertices* (not lying in one straight line), and the three straight lines joining these, called the sides Since no part of a plane can be inclosed by fewer than three straight lines, the triangle ranks as the simplest figure of its class, and plays a correspondingly important part in both practical and theoretical geometry

Congruence Theorems.—It is important to recognize the conditions under which two triangles may be known to be *congruent;* that is, alike in all respects except position in space, so that the one triangle is merely the other moved into a new position without change of form The most important theorems of this character have been known from very ancient times, and were handed down in the first book of Euclid's *Elements.*

Two triangles are congruent if two sides of the one are respectively equal in length to two sides of the other, and if these two sides are in each case inclined at the same angle.

Thus in figure 1, to be sure that the triangles ABC and abc are exactly alike, it is enough to know that $AB=ab$, $AC=ac$, and the angle at A=the angle at a It would *not* be enough to know that these same two pairs of sides were equal together with the angles at B and b, since in this case the triangle ABC might equally well have had the form of ABC' in the figure, and therefore not have agreed with abc in form.

Two triangles are congruent if the three sides of the one are equal respectively to the three sides of the other.

Two triangles are congruent if a side of one is equal to a side of the other, and if the angles at the ends of these equal sides are the same in both triangles.

Thus the triangles ABC and abc will be identical in form if

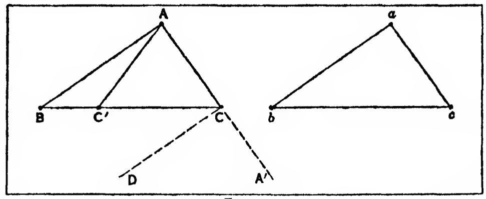

FIG. 1

$BC=bc$, the angle at B=the angle at b, and the angle at C=the angle at c

This theorem supplies the basis for the method of triangulation. If B and C are given stations whose position is known, the measurement of the angles ABC and ACB will determine, together with a knowledge of BC, the form of the triangle ABC, and so the position of A.

Two triangles are congruent if two angles of the one are equal to two angles of the other respectively, and if the sides opposite one of the equal pairs of angles are equal

This theorem is readily reduced to the one before by means of the property stated at the beginning of the next section The same consideration prepares us to accept the statement that two triangles may have the angles of one equal to the angles of the other without being congruent In such a case the triangles are similar in shape, but may be of different sizes.

Relations Between the Parts of a Triangle.—The foregoing remarks emphasize the fact that the three sides and the three angles are not six independent magnitudes to which any values whatsoever may be given For instance it is impossible to draw a triangle in which all the sides are equal and the angles unequal.

The simplest relation connecting the parts of a triangle in general is that *the sum of the three angles is two right angles.* This follows from the fact that, when one side is continued outside the triangle, the angle so formed on the outside is equal to the sum of the angles inside the triangle at the other two vertices. The latter relation is exhibited in figure 1 for the triangle ABC, the line CD, drawn parallel to BA, dividing the exterior angle into two parts, of which DCA' is equal to A, and DDC' to B. The relation between the three angles enables one to find the value of the third when two of the angles are known. Thus, if two of the angles are 60° and 70°, the third is 180°–60°–70° = 50°.

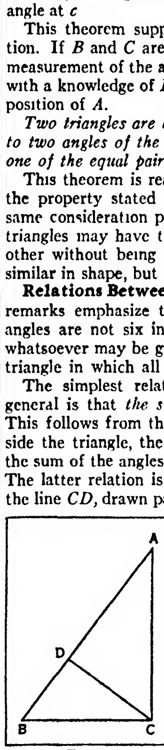

FIG. 2

It is convenient to consider here certain special forms of triangle. A triangle with two equal sides is called *isosceles.* Such a triangle has the angles opposite to these sides also equal. This is easily proved by joining the middle point of the unequal side to the opposite vertex and deducing the congruence of the two triangles so formed. The proof given by Euclid was much more elaborate, because Euclid did not permit the use of the middle point at a stage when the problem of finding it had not been taken up; and the theorem was nick-named the *pons asinorum,* and regarded at one time as a notable obstacle to the beginner in geometry.

A *right triangle* is one which has one of its angles a right angle. In figure 2 the triangle ABC has a right angle at C. Evidently $CB=AB\times s$, and $AC=AB\times k$, where s and k are proper fractions depending on the angle A, and not on the size of the triangle.

The ratios s and k are called the sine and cosine respectively of the angle A, and their theory constitutes the science of trigonometry (*q.v.*). If CD is perpendicular to AB, by the similarity of the three triangles, $BD = CB \times s = AB \times s^2$, *and* $AD = AC \times k = AB \times k^2$. Since $AD + BD = AB$, it follows that $s^2 + k^2 = 1$. On multiplying this equation by AB^2, it is seen that $BC^2 + AC^2 = AB^2$. Here the meaning of BC^2 may be understood to be the

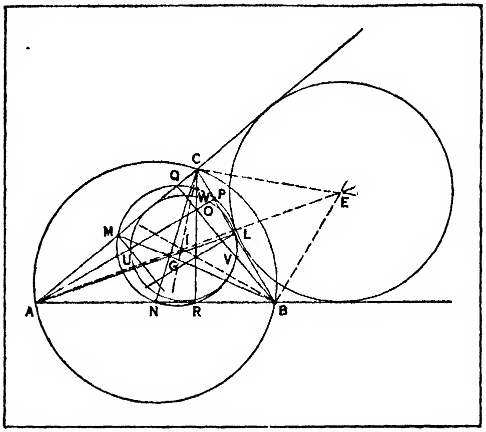

FIG 3

arithmetical square of the number of units in BC The side AB opposite the right angle is called the *hypotenuse* of the right triangle, and the result just obtained is that *the square of the hypotenuse is equal to the sum of the squares of the other two sides*, a theorem ascribed to Pythagoras (*q v*), and of the utmost importance in geometry.

Allusion may be made to two triangle inequalities. (1) *The sum of any two sides is greater than the third side;* (2) *the greater of two unequal sides has the greater angle opposite to it*

As supplementing the preceding statement (2) we have the *sine formula.* In fig. 3, if CR is perpendicular to AB, the sines of A and B are respectively $\frac{RC}{AC}$ and $\frac{RC}{BC}$. These are proportional to BC and AC, so that *the sines of angles are proportional to the lengths of the opposite sides* Also $BC^2 = RB^2 + RC^2 = (AB - AR)^2 + (AC^2 - AR^2) = AB^2 + AC^2 - 2AB\,AR = AB^2 + AC^2 - 2AB \cdot AC\,k$, where k is the cosine of A These two relations are of great importance in triangle computations.

Associated Lines and Circles.—It is only possible to quote summarily a few of the more interesting configurations that arise in connection with the triangle. The construction for the circumscribed circle (which passes through the vertices) reveals that the three straight lines drawn perpendicular to the sides through their middle points meet at a common point, the centre of the circle in question.

The centre of the inscribed circle (which touches the sides and lies between them) is the intersection of another set of concurrent lines, the three internal bisectors of the angles of the triangle.

The bisectors of two exterior angles, as BE and CE in fig. 3, meet at a point on the bisector of the interior angle at the other vertex, this point being the centre of another circle touching the three sides. Four circles in all are found to touch the sides.

The lines joining the vertices to the middle points L,M,N, of the opposite sides meet in a point G called the *centroid.* The perpendiculars AP, BQ and CR meet in a point O, called the *orthocentre.*

There is the remarkable theorem that the points L,M,N,P,Q,R and the middle points U,V,W of AO, BO, CO lie on a circle (the *nine-point circle*), and the still more striking result (Feuerbach's Theorem) that this circle touches the four circles touching the sides of the triangle.

TRIANGLE, in music, an instrument of percussion of indefinite musical pitch, consisting of a rod of steel bent into the form of a triangle. Suspended by a loop, it is played by means of a short steel rod. The tone of the triangle is clear and ringing, but it should have no definite pitch.

TRIANON, TREATY OF. The treaty of peace between the Allied and Associated Powers and Hungary was signed at the Trianon on June 4, 1920. Owing to the outbreak of Béla Kun's revolution in Hungary, the delegates of that nation were not summoned to the Peace Conference till Nov. 1919. Previous to that date, however, on June 13, 1919 the Supreme Council had decided upon the new frontiers of Rumania and Czechoslovakia and had published them The Hungarian Government received the treaty in Jan. 1920 and on June 4 it was signed at Trianon.

Though the separation of Hungary from Austria and its complete independence were recognized, the details of the Hungarian Treaty were otherwise very closely akin to those of the Austrian, the most important difference being that, while the Treaty of St. Germain was signed with the republic of Austria, that of Trianon was signed with Hungary, or with "the national Government of Hungary," a phrase permitting her to be regarded as a Government where the monarchy is temporarily in suspense Though Charles never abdicated the kingship of Hungary and there is no provision in the treaty for his deposition or for that of any Habsburg, he was formally deposed by a law passed by the Hungarian Assembly (after his attempted *Putsch*, Oct 1921) at the insistence of the Allies. (*See* HABSBURG.) On her admission to the League of Nations in 1922 Hungary submitted to the League a document pledging herself not to restore the Habsburgs without the consent of the Allies, and confirming the undertaking to the Conference of Ambassadors of Nov. 10, 1921.

Territorial Clauses.—The territorial clauses of the Hungarian Treaty reduced her to a population of 7,500,000 (1910 census), of whom approximately 6,250,000 are Hungarians (Magyars); 500,000 are Germans, 500,000 are Jews, 230,000 are Slavs and Slovaks and 50,000 are Rumanians Fiume was ceded to the principal Allies by article 53 and, after being erected into a free city, was eventually annexed by Italy (1924). Hungary lost to other nations over 3,000,000 Magyars, of whom 1,500,000 go to Rumania, nearly 1,000,000 to Czechoslovakia and 500,000 to Yugoslavia. Much of the Magyar population lost (as *e g*, the Székler area) consists of Magyar islands isolated amid a sea of Slavs or Rumanians The Pécs area, with its valuable coal mines, was returned and a line drawn in this area so as to give Hungary a defensible frontier. For economic reasons the three Magyar towns of Satul-Mare (Szatmár) Oradea-Mare (Nagyvárad) and Arad and the surrounding Magyar zone were given to Rumania.

Part V.—The military, naval and air clauses were almost exactly similar to those of the Austrian Treaty except that Hungary was allowed an army of 35,000 instead of Austria's 30,000. Part VI, *Prisoners of War and Graves*, and Part VII, *Penalties*, were the same as in the Austrian Treaty. (*See* ST. GERMAIN, TREATY OF)

Part VIII.—Reparation.—This section is verbally almost identical with the Austrian section, and both are a close imitation of the German. For various reasons it was not possible to fix the exact amount of reparation. But Hungary was forced to surrender all rights to her merchant ships on "the ton for ton, class for class basis," and her reparations in kind were to be fixed in three months by the Reparation Commission, which was to deliver cattle to Italy, to Rumania, and to the Serb-Croat-Slovene kingdom (Annex iv. to Part viii.).

Financial and Economic Clauses.—Articles 180–199 are mainly concerned with liquidating the Austro-Hungarian National Bank, thus separating the last link with Austria Part X., the economic clauses, calls for no special remark, nor does Part XI, Aerial Navigation The economic clauses are the same as the Aus-

trian, the latter like that of both German and Austrian Treaties Part XII, ports, waterways and railways, is mainly concerned with the regulation of the Danube, for which a statute was eventually drawn up. As in the case of the Austrian Treaty (Article 311), the Hungarian in Article 294 provides for the free access of Hungary to the Adriatic, though practically nothing has been done to secure it. Part XIII., labour, is the same in all treaties and Part XIV, miscellaneous provisions, calls for no remark

TRIASSIC SYSTEM or **TRIAS,** geological terms used to designate the lowest major division of the Mesozoic era—given by F. von Alberti (1834) owing to the division of the system into a threefold series in Germany, in contradistinction to the twofold division (Dyas) of the underlying Permian

Like the Permian (*q v*) the Trias is represented by two phases of sedimentation, the one continental as in Germany, the other marine—the latter being the normal aspect

Where the marine facies is developed the division between the Permian and Triassic systems, or in other words between the Palaeozoic and Mesozoic eras, can best be drawn by means of the faunas Where the continental facies occurs fossil evidence is scanty, and the general similarity of the deposits, together with their rapid changes in lithological type, makes it difficult to define the boundaries of the two systems. In Britain they are so closely knit that the term New Red Sandstone was formerly suggested by Goodchild for the combined Permo-Trias; and there is a tendency to revert to that grouping

Records of the continental phase reside in breccias, conglomerates, red and mottled sandstones, marls and clays, with beds of dolomite, limestone and coal, and layers of gypsum, anhydrite or rock-salt The coarser deposits consist of frost- or sun-riven scree material accumulated almost *in situ*, or as widespreading torrential fans Conglomerates afford evidence of transportation by water, whilst the oblique bedding of certain sandstones, coupled with the perfect rounding of many of the grains and the *dreikanter* form of some of the enclosed pebbles, point to the action of wind Some of the sands may represent dunes, but the majority were deposited with layers of mud in sheets of water which were shallow and subject to frequent desiccation Of this we have evidence in reptilian footprints, fossil rain-pits, ripple-marks, sun-cracks and precipitated salts. Fresh influxes of water are shown by pellets of sun-dried mud and salt-pseudomorphs included in the sandstones

GERMANY

The Trias occupies a larger area than any other formation in Germany and is classified as follows —

Keuper	Rhaetic	Sandstones and clays with *Avicula contorta* Bone bed
	Gypsekeuper	Steinmergel and Stubensandstein Gypsekeuper and Schlifsandstein
	Kohlenkeuper	Grenzdolomite Lettenkohlensandstein Dolomitic limestones and marls
Muschelkalk	Haupt-Muschelkalk	Trigonodus beds Nodusus beds Prochiten Kalk
	Anhydrite group, dolomite, and marls and limestones with rock-salt, gypsum and anhydrite	
	Wellenkalk, with Schaumkalk zones near top	
Bunter	Upper or Roth variegated clays or marls with plants	
	Middle or Hauptsandstein (and Vosgessandstein), with subordinate conglomerates	
	Lower: Sandstones (some clayey) and shales, with oolite (Rogenstein)	

In North and Central Germany the Zechstein clays are succeeded conformably by clayey Bunter beds. In other districts there is unconformity, with overlap of higher members of the Bunter.

The Röth contains rock-salt and bivalve-bearing beds of limestone and dolomite (Rhizocorallum Dolomite)

The Muschelkalk—mainly calcareous—is the only division with a considerable fauna, which is poor, however, in comparison with that of the marine deposits of the Alps. In extent it is inferior to the Bunter, its westward limits stopping short of central France, although it occurs near Toulon and Montpellier In Alsace-Lorraine the Lower Muschelkalk takes on a sandy facies (Muschelsandstein) as does the Middle division in part of Luxembourg The Upper Muschelkalk is the richest in fossils, being characterized by *Ceratites nodosus, C. semipartitus* and *C enodis.*

The Keuper (*Marnes irisées* of France) comprises red and variegated clays, pale sandstones, limestones, dolomites and impure coals Estuarine conditions in the Kohlenkeuper are shown by *Myophoria goldfussi* and *Estheria minuta* as well as relics of fishes (*Acrodus, Ceratodus*, etc.), and terrestrial conditions by Labyrinthodonts and Saurians (*Mastodonsaurus*, etc) The Gypsekeuper contains rock-salt in Lorraine Stubensandstein and Schlifsandstein occur in south Germany The former yields saurian remains (*Aetosaurus ferratus* and *Belodon kappfi*), the latter plants (*Equisetum arenaceum*, etc)

Rhaetic beds, typical of the Rhaetic Alps, mark the return into western Europe, by a wide-spread marine transgression, of the seas that characterized the subsequent Mesozoic era, and form a passage between Keuper and Lias (Infra-Lias of France), although the molluscan fauna and the flora suggest a Triassic age In Germany the Rhaetic consists mainly of pale sandstones and grey shales. The fauna—with *Avicula* (*Pteria*) *contorta, Protocardium rhaeticum,* and other forms—is not rich, but highly important, because of its great extent Remarkable features are the bone-beds, a few inches thick, which occur at several horizons, crowded with teeth, bones, scales and coprolites of fishes and reptiles. Here are found *Ichthyosaurus* and *Plesiosaurus*, anticipating their maximum development; while remains of *Belodon* and *Mystriosuchus* serve as a link with Triassic Stegocephalian reptiles Teeth of *Microlestes antiquus,* the oldest known mammal, occurred near Stuttgart

Trias of German type, including Muschelkalk, extends at intervals beyond the Pyrenees to the south of Spain. Triassic rocks occur in Heligoland and there is an outlier of Upper Triassic in the south of Sweden which includes coal-bearing Keuper and marine Rhaetic Trias with Muschelkalk extends from Silesia into Poland In north-west Russia the beds belong chiefly to the Tartaric stage—in part only Triassic.

BRITAIN AND IRELAND

As in Germany (excluding the Rhaetic) the Trias of Great Britain is of continental facies Its outcrop in England and Wales is narrow in the south-west, but expands in the Midlands and bifurcates at the southern end of the Pennines, one extension projecting into Durham, the other into Cumberland and Westmorland, whence it extends into parts of south Scotland. Other occurrences are found in the Western Isles and on the opposed shores of Moray firth Denudation has removed the Trias from all but north-eastern Ireland.

No representative of the Muschelkalk has been found.

The deposits usually follow the Permian (where developed) with conformity, although minor discordances occur here and there Tending to fill up the Permian basins, they spread, in many cases, further afield and rest upon still older rocks, their higher members often overlapping their lower divisions The typical sequence is as follows, and is compared with that occurring west of the Pennines:

The relationship of Trias to Permian is difficult to determine. As stated elsewhere (*see* PERMIAN) it has been claimed that part, if not all, of the Bunter of Nottinghamshire is equivalent to a great part of the Permian Zechstein of Durham. This awaits more general acceptance or denial: what may be conceded

	S. Lancashire and the Midlands	Maximum thickness	Furness (Lancs.), Westmorland, Cumberland and Isle of Man	Maximum thickness
	Rhaetic beds (marine)		? Rhaetic beds .	..
Keuper	Marls with gypsum	Over 2,000	Stanwix Shales (saliferous) .	About 1,000
Keuper	Waterstones	200		
Keuper	Lower Sandstones and, or, .	200	? Waterstones . .	
Keuper	Basement conglomerates and breccias	400		
Bunter	Upper Mottled Sandstone .	500		
Bunter	Pebble Beds . .	700	Kirklinton Sandstone St. Bees Sandstone	Over 3,000
Bunter	Lower Mottled Sandstone (? Permian)	650	St Bees Shales, with gypsum (Permian-Trias) .	Brockrams 200

is that probably the Lower Mottled Sandstone of South Notts may represent some of the highest Permian strata occurring farther north The Lower Mottled Sandstone of Wirral[1] (Cheshire) is possibly also of Permian age, whilst there are grounds for the belief that the St. Bees Shales (correlated with the Durham Permian Marls) are transition beds and may represent, in part at least, Lower Mottled Sandstone of other areas

The Mottled Sandstones consist typically of alternations of soft red and variegated sandstones, generally without pebbles In Nottinghamshire and south Yorkshire the Upper group is absent The Pebble Beds are harder red and brown sandstones, with, in places, strong false-bedding, aeolian sand grains, dreikanter, etc In some localities they contain abundant quartzose pebbles, probably derived from local sources now concealed In the Midlands they form undulating country typically expressed in Cannock Chase and Sherwood Forest and furnish a first-class water-bearing horizon In Devon is the "Budleigh Salterton Pebble-bed," with pebbles derived both from Normandy and from a northern local source These Pebble beds were accumulated chiefly in shallow water, but some of the coarser deposits may represent dune sands The absence of pebbles, and the finer grade of material, makes it difficult to distinguish the Bunter of north Yorkshire and Durham from the Keuper. The St. Bees and Kirklinton Sandstones also are almost devoid of pebbles. Breccias (Brockrams) were formed continuously to the west of the Cumberland hills both before and during the deposition of the Zechstein, St Bees Shales, and part of the St. Bees Sandstone —emphasizing the intimacy of these deposits

Keuper deposits extend into most of the above described regions, in places slightly unconformable to the Bunter, beyond the limits of which they frequently extend, and may have local breccias at the base Of these the best known is the "Dolomitic Conglomerate" (Bristol district), a shore-line breccia of the inland Keuper sea which gradually buried a well-dissected landscape of older rocks It is largely composed of Carboniferous Limestone set in a dolomitic matrix, but local patches contain Old Red Sandstone It has yielded reptiles (*Thecodontosaurus, Palaeosaurus*) The Keuper of Charnwood Forest, Leicestershire, conceals mountains of which the tops only are now visible

Typical Keuper Marl consists of rhythmic alternations of chocolate red marls, red shales and pale dolomitic sandstones (skerries). In the Midlands is the Arden Sandstone with *Estheria, Hybodus, Acrodus,* Labyrinthodonts and plants The Waterstones are variegated shales and marls with soft red sandstone; whilst the Lower Keuper Sandstones are false-bedded freestones—not always present. In Worcestershire the latter have yielded scorpions, and, near Birkenhead, Cheshire, footprints of reptiles.

At the top of the Keuper is a belt of "tea-green marls" which, in the south-western counties, pass up into fossiliferous grey shales (Sully Beds). These shales have been classed with the Rhaetic.

Gypsum and alabaster appear at several horizons, the most important occurring in the Midlands at 60–70 and 160 ft. respectively below the Rhaetic. They are extensively mined (Newark, Chellaston, etc) In Cheshire and Worcestershire great beds of salt set in at lower horizons, and this mineral appears also at Puriton in Somerset The Stanwix Shales of the Carlisle district carry gypsum, whilst those of the Isle of Man, Walney Island and Preesall, Lancashire, have deposits of rock-salt.

In Britain the Rhaetic (or Penarth) Beds usually consist of White Lias (well developed in the south-west) on dark *Avicula (Pteria) contorta* Shales Certain smooth-textured White Lias limestones yield a landscape marble (Cotham): at the top is the sun-bed or "jew-stone" At the base of the *Avicula* Shales is a bone-bed with fossils similar to those of Germany, including the mammal *Microlestes*, which is also found in the Sully Beds

In South Scotland the Annan Sandstone is correlated with the St. Bees Sandstone, whilst in Arran the Bennan Shales and Auchenshaw Sandstones and Shales are considered to be Bunter, and the overlying marls and shales (Levencorroch and Torr nan Uain) Keuper. At the top are grey-green marls succeeded by Rhaetic Beds Triassic rocks occur also in Skye, Raasay and Mull—breccias, conglomerates, marls and cornstones, with gypsum in the upper beds—and at Morven and Ardnamurchan (Argyllshire) and Gruinard bay (Ross-shire) There is a complete passage into the Lias here The Trias of Elginshire south of Moray Firth contains sandstones with a reptilian fauna. That of the lower beds is allied to the Karroo forms, whilst the upper beds (Lossiemouth) contain *Hyperodapedon gordoni, Ornithosuchus woodwardi*, etc, which are undeniably Triassic.

In Ireland existing Triassic deposits have been largely protected by Tertiary basalts Both Bunter and Keuper are represented (Lagan valley) very similar to that of the Cumberland coast at Carrickfergus and Kilroot, near Belfast, rock salt is found in the Marls Rhaetic beds with *Avicula contorta*, etc., link the Keuper with the Lias (Larne; Collenglen, near Belfast).

THE ALPS

The marine Trias is frequently referred to as "Alpine," "Mediterranean" or "Pelagic" In Europe and eastwards through Asia it forms part of the deposits of the great Mediterranean sea, or "Tethys," situated north of Gondwanaland (*See* article PERMIAN) The facies is distributed widely in southern Europe, particularly in the eastern Alps, Apennines, Sicily, Balearic Islands, Spain, Balkan Peninsula and part of the Carpathians

In the Alps, where the rocks form a broad zone on both sides, sandy rocks are subordinate to limestones, dolomites and marls, whilst the fauna makes that of the German Muschelkalk appear poor by comparison The following divisions are recognized, chiefly in the eastern Alps —

Keuper	Rhaetic	Dachsteinkalk and Kossener beds	with *Megalodon triqueter* and *Avicula contorta*
Keuper	Noric	Dachsteinkalk and Hauptdolomit (or)	„ *Megalodon triqueter, Worthenia solitaria*, etc
Keuper	Noric	Hallstatterkalk	„ *Pinacoceras metternichi, Cladiscites, Halorites*, etc
Keuper	Karnic	Raibl beds	„ *Tropites subbullatus* and *Trachyceras aonides.*
Keuper	Ladinic	St Cassian beds	„ *Trachyceras aon*
Keuper	Ladinic	Wengen beds	„ *Daonella lommeli*
Keuper	Ladinic	Buchenstein beds	„ *Protrachyceras reitzi, Ceratites, Arcestes*, etc
Muschelkalk	Anisic	Alpine Muschelkalk (with Mendola-dolomite, etc.)	„ *Ceratites trinodosus, Athyris trigonella, Spiriferina fragilis, Pinacoceras, Gervillia socialis*, etc.
Bunter	Scythic	Werfen beds	„ *Myophoria costata, Avicula clarai, Ceratites cassianus, Tirolites*, etc

The Werfen beds (Salzburg) are conformable to the underlying Permian and consist of red sandy shales and beds of gypsum and rock-salt, with impure limestone in the upper part The

Alpine Muschelkalk is highly fossiliferous and differs in many respects from that of Germany, being of truly marine character. Typically the Ladinic consists of limestones, dolomites, tuffs and lavas, though there is also a calcareous and a dolomitic facies. In the St Cassian beds the fossils are dwarfed

The Raibl beds indicate a regression of the sea, evidenced by plant-bearing sandstones (Lunz), and marls with gypsum The Rhaetic consists generally of marly limestones forming a thin but continuous sheet

The small masses of limestone of Bogdoberg (Kirghiz Steppes, south Russia) overlying red sandstones and marls are portions of Muschelkalk of Alpine type on the equivalents of the Bunter.

Marine Trias occurs also in Asia Minor, many parts of Asia as far east as China, the Indo-Pacific islands, Japan, Spitsbergen, New Zealand, New Guinea, Timor, Peru, Colombia, Mexico and western North America With the exception of the last these areas lie north of or on the margins of Gondwanaland. Certain of these occurrences are dealt with below.

ASIA

In India the finest development of marine Trias occurs in the Himalayas In Spiti (Lilang), Garhwal and Kumaon and on the north-west extension of the same geo-synclinal axis in Kashmir the rocks comprise three subdivisions corresponding to the Alpine Bunter, Muschelkalk and Keuper (with Rhaetic). The Bunter, which rests conformably on the Permian Productus Shales, consists of 50 ft. of shales and limestones with an ammonite fauna (*Otoceras, Ophiceras, Meekoceras*) The Muschelkalk is chiefly concretionary limestones, 400 ft thick, with *Ceratites, Siberites,* etc., and, at the top a Daonella (lamellibranch) limestone. The Keuper comprises 2,000 ft of shale and marl beneath thick limestones and dolomites with a cephalopodan fauna The lower division corresponds to the Karnic and Noric stages, whilst the limestones probably represent the Rhaetic

In the north-west Himalayas (Sirban Mountains, Hazara) Trias rests unconformably on Devonian shales and limestones (Infra-Trias). Felsitic lavas are succeeded by limestones from 500–1,200 ft thick, with characteristic fossils

Trias of reduced thickness and comprising only the Lower and part of the Middle division occurs in the western part of the Salt Range where it caps the Permian Productus Limestone The Lower division consists of thin limestones with an extraordinary abundance of *Ceratites.* The Middle, or Muschelkalk, contains many cephalopods

In north Baluchistan shales and slates with a few limestones represent the Rhaetic stage It contains *Monotis* and cephalopods (*Didymites, Halosites*) and rests unconformably on Carboniferous Fusulina limestone. A similar development occurs in the Arakan Yoma of Burma whilst in the Northern Shan States the Noping beds, with *Avicula contorta,* suggest a Rhaetic age

Peninsular India was at this time joined up to Australia and Antarctica, Madagascar, South Africa, and South America, and formed part of the continent named Gondwanaland (*See* article PERMIAN) The Trias is represented by the Middle Gondwana Series which is divided into three groups:—Panchet, Kamthi and Maleri (or Denwa) corresponding approximately to the divisions of the German Trias In the type area (Satpura Range) the rocks consist of massive sandstones, conglomerates, grits and shales devoid of coal seams and are unconformable to the Permian Damuda Series. Vegetation, hitherto profuse, became scanty or failed

The Panchet group (1,500 ft) is of restricted development and is overlapped by the Kamthi division (3,000–8,000 ft.), whilst the Maleri is of variable thickness and occurs but locally. In the Panchet group vertebrate remains include fishes, Labyrinthodonts (*Stegocephala*), Amphibia (*Glyptognathus,* etc.) and reptiles (*Dicynodon,* etc.), whilst the Kamthi group contains similar forms as well as a flora with *Glossopteris, Gangamopteris, Phyllotheca,* etc. The clayey Maleri group has remains of fishes (*Ceratodus*), Labyrinthodonts (*Gondwanosaurus*) and reptiles (*Hyperodapedon,* etc.). Biologically the fauna agrees closely with the English Trias.

AFRICA

In South Africa the Triassic deposits are continental and form the greater part of the Karroo Beds covering much of what is now the Union They occur also in south-west Africa, along the borders of the Kalahari, over parts of Rhodesia, Portuguese Africa and regions farther north.

In the Cape Province, the Permian Ecca Beds are followed by the Beaufort and Stormberg Series, the former divided into Lower, Middle and Upper Beds, the latter into Molteno Beds, Red Beds, Cave Sandstone and Drakenberg Volcanics In central Transvaal the Beaufort Series is absent and the Stormberg Series is represented by Bushveld Marls, Sandstone and Amygdaloids. The Lower Beaufort Beds, with their reptilian remains (*Pariasaurus, Dicynodonts,* etc), are considerd by du Toit to be Upper Permian and the Volcanics to cover the period from Rhaetic to Lias, the Middle Beaufort are Lower Triassic and the remainder (Upper Beaufort–Cave Sandstone) Upper Triassic.
